The two facts you have before you, *viz.*, the existence of organisms in vaccine matter, and the occurrence of similar organisms (not ascertained to be identical with the other) in the lymphatics, suggest the probability of their having to do with the morbid process, but cannot be accepted as an adequate proof that they possess the property of reproducing or propagating the disease. For the establishment of such proof with respect to any contagium, it would have to be shown either that when deprived of its organisms, though otherwise unal-

tered, it is deprived of its activity; or that when the organisms are introduced alone, they manifest the contagious property of the liquid or tissue from which they were derived. An imperfect approach towards the first of these demonstrations was made in Chauveau's experimental investigations; for it was shown that many contagious liquids lose their activity when they are deprived of the suspended particles in which whatever organisms they contain are included. The second demonstration must, with our present means of observation, be regarded as impossible, on the ground that the bodies in question are so minute that there is not the slightest prospect of our being able to separate them in anything like purity.

Another reason why no method based on the separation of the living contagious particles could possibly be successful is, that the particles themselves, if removed from the conditions adapted to them, would in all probability, as a direct consequence of that change, entirely alter their properties. Even organisms much higher in the scale, for example, many plants containing active principles, become inert when removed from an appropriate to an inappropriate soil. Much more, therefore, should we expect a similar result in the case of organisms, the vital processes of which are so much more under the influence of conditions.

Considering these difficulties, I set myself last year to consider whether there might not be methods of investigation within reach, which, if they did not come up to the strict requirements of the problem, might help us to approach it. If, it occurred to me, in any disease capable of propagation by the insertion of a contagium containing recognisable living organisms, however minute, it were in our power to observe the behaviour of these organisms during and after the act of infection, even if it were impossible to separate them from the contagious liquid or substance along with which they were introduced into the body of the infected person or animal, we should be able, by comparing the transformations or other manifestations of vital activity in the lower organism or parasite, with the functional derangements and textural changes in the higher organism resulting from the infection, to ascertain with the utmost precision the nature of the relation, if any, between the two series of phenomena. If this method could be carried out, I thought it might be anticipated with great certainty that it would be possible by means of it to determine in the particular case, that the one process is or is not the efficient cause of the other.

As regards many infective or contagious diseases, the application of such a method would be impossible, for we have no sufficient knowledge either of the door by which the contagium enters, or of its whereabouts in the organism after its entrance. In the case of small-pox these difficulties do not exist; and of all human contagious diseases it is theoretically the most fitting for such an inquiry. We have the virus, we have the organism, we have the process. We know how the virus enters. We know how it is scattered over the surface as thistle down is scattered over a field; and how each seed sown serves as a centre of origin for a morbid process, complete in itself. If we could—imitating Dr. Weigert's method, but carrying it out much further than he did—not merely search for our organisms at the sixth day, but at each successive period in the local process, from the first sign of functional disturbance in the rete Malpighii at the seat of the future papule, to the maturation of the pustule, and could trace the two developments—that of plant-life life on the one hand, and that of pathological and structural change on the other—going on side by side; and, as has been already explained, see that both were correlative manifestations of the same action, the object would, as regards small-pox, be accomplished.

But here we are met by an insurmountable practical difficulty. No opportunity is ever likely to be afforded us of investigating the pathological anatomy of small-pox in those early stages, about which it is most important to obtain information. Happily, comparative pathology affords us a means of circumventing this difficulty. In the sheep there is a disease which, as regards its origin, progress, and local manifestations, is the very counterpart of human small-pox.

The virus of sheep-pox, as I had the opportunity of observing in 1869, contains organisms similar to those of small-pox and vaccine. The analogy, therefore, is complete—so complete, indeed, that whatever can be ascertained by observation as to the behaviour of the organism of sheep-pox within the body of the infected animals, might be applied with the greatest confidence to the elucidation of the corresponding processes in human disease. On these grounds, I suggested to the Chief of the Medical Department of the Government that my colleague at the Brown Institution, Dr. Klein, should be requested to undertake an anatomical investigation of the disease, for which I was enabled to obtain material through the kindness of Professor Chauveau of Lyons and Professor Cohn. The results have been already communicated to the Royal Society, and will shortly be published in the *Philosophical*

* The reader will find a full account of these investigations in a prefatory paper entitled Recent Researches on the Pathology of the Infective Processes, in the first of the series of scientific contributions about to be issued by the Medical Officer of the Privy Council. It is expected that the first number will be out in a few days.

† For the information of the reader, I transcribe the passage referred to. "The drawing given by Dr. Sanderson conveys no idea of the actual appearance of the matter represented. A few minute circles may be made to indicate very fairly the appearance of microscopic fungi; but they are no more like the particles of vaccine lymph, or any contagious poison, or any kind of living matter known, than an oil-globule or an air bubble is like a white blood corpuscle or a pus-corpuscle. Such illustrations only help to retard investigation, and to convey erroneous ideas regarding the character of the matters referred to" (*Disease-Germs*, second edition, p. 237). There can be no doubt that my drawings are not like those of Dr. Beale; but that they give a true notion of the objects represented, the reader may satisfy himself by comparing them with those of Professor Cohn; the resemblance between them is complete. No doubt Dr. Beale, regarding us both as "blind leaders of the blind", would find both representations alike faulty. The explanation of the discrepancy is obvious. I had before me certain spheroidal bodies of extreme minuteness, which I represented in my woodcuts in the usual conventional way—*i.e.*, by what Dr. Beale calls "minute circles". Professor Cohn's figures are of the same character. Dr. Beale had before him "bioplasts" of various shapes and sizes, all admirably drawn (see *Disease-Germs*, fig. 66). It could hardly be expected that the pictures should be like each other.

Transactions, as well as in the forthcoming Report of the Medical Officer of the Government.

Before giving a short account of them, I must refer for a moment to well known facts relating to the development of the pustule in human small-pox. Each pustule must be regarded as what is called in pathology a focus of inflammation—an acute process which has a centre of origin. Where is this centre? If we refer to a diagram of the skin, as to a map, we fix the first localisation of the process at the junction-line between corium and epithelium, *i.e.*, between the structure called the rete Malpighii, and the very vascular layer beneath it which forms the papillae. Let us consider what lies on each side of that line. Above it there are small cells, polygonal and closely packed—the growing cells of the epithelium. As you trace the stratum upwards, they flatten, then suddenly change their character and become horny. This we call the natural *stratum corneum*. Below the line referred to, there are papillae composed of a dense but transparent tissue, so closely packed with loops of capillaries that, when these are distended, it looks as if it were all blood-vessels. Below this is a layer where there are fewer vessels, but they are still very numerous.

The anatomical changes in the structures of the corium and epidermis which result in the formation of the small-pox pustule have their principal seat and origin on either side of the well defined line, which, as I have just said, separates in a vertical section of skin the rete Malpighii from the vascular tissue of the papillae. Above that line, the pathological processes consist at first merely in overgrowth—*i.e.*, in germination of the cells of the deep layer of the epidermis; but, as it progresses, two remarkable changes occur. Cavities (the future "vesicles" or "cells") form in the Malpighian layer, which are at first full of clear liquid, afterwards of pus; and, secondly, the epidermis-elements appear to fuse together into a horny material. This horny material constitutes not only the covering of the vesicles, but the septa by which the adjoining cells are separated from each other; and it is by the shrinking which attends its formation that the central depression afterwards observed is produced. In the corium, on the other hand, the lymphatic spaces fill, the tissue swells, and thus the prominence or "papule" is formed.

In sheep-pox, the same changes take place; but they have been much more completely studied, as I have said, by Dr. Klein. To save time, I must carefully avoid all that, however interesting, is not essential. Let me draw your attention once more to the rete Malpighii and to the superficial lymphatics of the cutis. In the rete, there is at first a general germination. Then certain cells become distinguished as being larger; these expand by vacuolation; they become cysts. The cysts coalesce, and thus are formed cavities (the cells of the older pathologists) in the thickened rete. In the corium, we have filling out of the tissue by liquid which occupied the interfascicular spaces of the lymphatic network. Then (tracing the process further) we observe that, in the rete, the vesicles continue to enlarge, and their contents alter. Instead of containing clear liquid with granules, they are full of pus-corpuscles. In the corium, the change is of the same nature, but goes on earlier; the whole tissue becomes inundated with leucocytes.* This inundation begins from the lymphatics, the appearances being such as to suggest an obstruction or blocking up of these vessels. Rapidly the tissue of the corium becomes fuller and fuller of corpuscles, the final act being the extension of the cellular inundation to the rete Malpighii. How do they get there? They are certainly not formed in the vesicular cavities. Dr. Klein has no doubt that they migrate into the vesicles from the papillary layer below, by virtue of their amoeboid movements.

As yet I have said nothing about the organisms. It will be remembered that Dr. Weigert found them only in the early stage of the pustule of small-pox; so here it would be in vain to look for them in the stage of suppuration. With this consideration in mind, Dr. Klein devoted his whole attention to the early changes. I may as well state at once that the anticipation that the early stages of the papule would be accompanied by the development of vegetation has been realised. The process has been studied both in the primary inoculation-pustules and in the general eruption, with results which may be thus stated. From the first, the cavities in which liquid collects, whether the lymphatics of the corium or the vesicular cavities of the skin, begin to show indications of containing organic forms. As the process is observed in sections made at various stages, its nature becomes more and more manifest. At first, it might be said, "Oh, these are merely the ordinary septic organisms with which we are familiar". Soon, however, this becomes impossible. First, the form which is most cha-

racteristic—that of the *rod*—is entirely absent. Secondly, the stage of the process is not that at which ordinary septic bacteria present themselves. In all infective inflammations, when they assume the destructive character, bacteria may appear in the inflammation-products, but they never appear in the early stages of the process.

Then, finally, the development of the vegetations, whether it was examined in the primary pustules or those of the general eruption, whether in the corium or epidermis, presented everywhere the same characteristics—characteristics which differed entirely from anything we have up to this moment had under our consideration. It consisted in the formation of a felt-work of extremely delicate filaments, which, although they were not jointed, were unquestionably branched, and gave off at the growing ends minute acro-pores or conidia, after the manner of the fungi of the penicillium group. These *mycelia* were first discovered in the initial stage of the disease in the lymphatics. Although the most scrupulous precautions were used—the portions of skin examined being plunged in the absolutely fresh state into alcohol—the fact was so strange, so unexpected, that it could hardly be credited. Whatever doubt, however, existed, was at once removed when it was found that the development was repeated in the "cells" or vesicular cavities of the epidermis, the same forms exactly presenting themselves; and the intimate relation of the whole process to the disease was rendered still more certain when it was observed that, on the appearance of the secondary eruption at the tenth day after inoculation, each of the small papules was an epitome of the large one, not only as regards the structural changes, but also as regards the evolution of plant life which was associated with it.

[In the remaining portion of this lecture, with which the subject will be concluded, were noticed the results of recent researches regarding the only other diseases in respect of which a definite relation between contagious processes and specific forms has, as yet, been made out, *viz.*, relapsing fever and the splenic fever of cattle.—J. B. S.]

ON THE APPLICATION OF COTTON-WOOL TO THE MEATUS AUDITORII.

IN the JOURNAL of January 9th and February 20th, correspondents accuse cotton-wool of being injurious to the ears; and they seem acquainted with only this, the smallest (and avoidable) portion of its effects. It is true that, if dry cotton-wool be pushed far into an ear whose cutaneous lining is already in a congested or irritable condition, it will most likely do much more harm than good. The value of cotton-wool, properly employed, in cases of otorrhoea and perforated or lost membrana tympani, is beyond price, and none the less real because not in vogue with German aurists, who somehow seem to have adopted modifications of Toynbee's India-rubber artificial membrane, rather than Yearsley's cotton-wool substitute. In England (and in America too, I believe), the preference is quite the reverse; and I should say that, in this country alone, there must be hundreds of persons who are daily introducing and wearing these little pledgets of cotton-wool, pushed home against the remnants of their "drums", not only without the slightest inconvenience, but with immense benefit. I know of a goodly number myself. As a rule, these drosses are not introduced dry, but saturated with plain water, glycerine, oil, or other fluid, according to circumstances; and it is a good plan to remoisten before withdrawing them, if they have been in any time. I see that the ear-fungus from which D. McD. suffered is said by one German aurist (Bezold) to be caused by the use of olive-oil; but, if that be so, one would think that the parasite would more frequently be met with than it is.

G. F. HENDERSON, Brighton.

POISONING BY BICHIROMATE OF POTASH.

A PHOTOGRAPHER in this neighbourhood recently drank a quantity of a strong solution of bichromate of potash, having mistaken the jug for another which contained ale. I found him very prostrate, sweating profusely, and complaining of severe abdominal pains. He was also slightly purged, the evacuations being of a greenish yellow colour. The pupils were dilated, and the pulse very weak and fluttering. I administered sulphate of zinc in water two or three times, until vomiting and active purgation had been induced. Subsequently, olive-oil was given him. He remained very weak for some time, and the stomach could only tolerate the mildest food.

LOUIS LEWIS, M.R.C.S., Albert Street, N.W.

* From an abstract just received of Dr. Weigert's further researches on small-pox, it appears that the migration of leucocytes takes place in the pustule of this disease in the same way as above discussed in sheep pox.

THE CROONIAN LECTURES ON ADDISON'S DISEASE.

Delivered at the Royal College of Physicians, London.

By E. HEADLAM GREENHOW, M.D., F.R.C.P., F.R.S.,
Physician to and Lecturer on Medicine at the Middlesex Hospital.

LECTURE II.

(Concluded from p. 371 of last number.)

It will be remembered that, in dealing with the total number of three hundred and thirty-two cases bearing upon the subject of Addison's disease, I set aside, in the first instance, for subsequent discussion, all those which I found reported as bronzing or discoloration of the skin without disease of the suprarenal capsules. These cases are twenty-one in number; and a brief analysis will show that, in almost all of them, the abnormal pigmentation was due to one or other of the pathological conditions which I have mentioned.

Two of the twenty-one cases published by Vernois and Averbeck precisely resemble the case of the woman exhibited by me at the Pathological Society; the age, circumstances, meanly habits and state of health, as well as the characters of the discoloration, having been nearly identical in all the three patients. The patients in these two cases died, and the capsules were found to be normal. It is significant of the confusion which prevails on this subject, that Averbeck, who did not consider his own case as a true example of Addison's disease, nevertheless tabulated the parallel case of my patient, who recovered, among the so-called cured cases of that disease; which, as he justly observes, must be received with suspicion. In three other cases published by Puech and Gordon, there was constitutional syphilis. In two cases recorded by Sloane and Luton, the darkening of the skin was associated with phthisis. The first patient had suffered from liver-complaint with permanent discoloration of skin; and, although the whole surface was bronzed, the mammae round the nipples were much paler than the surrounding parts, and there were many white spots on the breast and back. In two other cases related by Gibb and May, there was disease both of the lungs and the heart. Dr. Gibb's patient had aortic disease, which sufficiently accounted for the pale bronze hue of the face and neck; whilst in Mr. May's case the patient had also had gout, and the small brown spots scattered over the normal coloured skin point to the possible remains of some gouty eruption. In four cases published by Hutchinson, Harley, and Fricke, the discoloration dated from attacks of fever, jaundice, and hepatic derangement. Mr. Hutchinson's patient died of pneumonia, after an illness of fourteen days. His skin had been dark from the time he had had yellow fever in the Crimea. The entire surface was more or less bronzed, and the pigment was chiefly situated in the rete mucosum, but the face and hands were the lightest parts; whereas I need not say that they are generally the darkest parts in Addison's disease. In one of Dr. George Harley's cases, the darkening of the skin followed an attack of jaundice, and the patient remained five years in good health. The face, neck, and arms were dark; but the discoloration of the body was diversified with irregular white patches. The patient died of diseased liver and ascites. In Dr. Harley's other case, the patient had suffered during four years from occasional hepatic symptoms and gastric disorder. The face, arms, and trunk were all of a dark bronze colour, except the scar of a burn on the breast; but apparently the discoloration was quite uniform, and, unfortunately, the condition of the liver was not noted. In Dr. Fricke's case, the bronzing was limited to the forehead, face, and neck, and merged into jaundiced skin. The patient had suffered from ague, and died of cirrhosis of the liver. A case allied to these, but much more complicated, is reported by Dr. Merkel. The man's skin had been always dark; he had suffered from ague, and died of bronchitis and pleurisy. He was found, on *post mortem* examination, to have a large liver and spleen; and there was fatty degeneration of the heart, liver, and kidneys. The whole surface was bronzed, equally on covered and uncovered parts; and there were large grey-black patches on the buccal mucous membrane. Two cases of discoloured skin without disease of the suprarenal capsules, recorded by Dr. Bucknill and M. Regnard, occurred in women who were maniacal at the climacteric period of life—circumstances in which extreme dusking of the skin is by no means uncommon. Two cases of internal cancer, not involving the suprarenal capsules, are reported by Mitchell and Fremy as presenting a certain degree of discoloration of skin;

though of the first, it is only said that the skin became of a leathern hue, much darker in eczematous scars and in the site of a blister than in other parts; and of the second case, that, some days before death, the skin assumed in places an evident bronze hue. Dr. Hodges found on the bodies of two old men, one of whom died insane, and the other of age and debility, general darkening of the skin, with a bronze hue on the genital organs; but the face and other parts were much less discoloured.

There still remains one case of bronzed skin without disease of the suprarenal capsules, published by Rossbach in Virchow's *Archiv* for 1870, which requires more special notice. The case is most fully reported, and, on the supposition that it is a true case of Addison's disease, is made the basis of a new theory on the pathology of that disease, to which I must hereafter revert. The patient, a lady aged 62, had always been prone to excitement and sleeplessness; and these natural tendencies had been aggravated by long continued distress of mind. She suffered from anæmia, debility, loss of appetite, occasional vomiting, and also from pains in the epigastrium and in the right scapula, which she had hurt by a fall. These pains gradually extended round her body with all the violence of the neuralgia of shingles, and were always worst at night. Scleroderma began to develop on the right hand and forearm, and spread more or less to other parts of the body. The skin and subcutaneous tissue became as hard as stone, split, and formed fissures; and, together with this rare and peculiar cutaneous affection, appeared a dark and extensive pigmentation of the skin, of which large patches sometimes developed in a single night. Meantime, the patient's restlessness of mind and body increased; she could bear no position in or out of bed for fifteen minutes together, and at length she became totally sleepless and actually deranged at night. Towards the close of life, her pulse was quick, hard, and occasionally intermitting. She had albuminuria and anasarca, and sank under a slight attack of pneumonia, after nine months' illness. The cerebellum was very soft; the brain and lungs were oedematous; and there was some fatty degeneration of the heart, liver, and kidneys; but the suprarenal capsules and neighbouring nerves were perfectly normal. The pigmentation of the skin was coextensive with the scleroderma. In the paler parts, it was produced by innumerable dark points, and on the darkest parts there were dendritic patches of colourless skin. On examination under the microscope, the pigment was seen to be deposited chiefly in the papillæ and upper layers of the cutis. I need not point out in detail the totally opposite characters of this discoloration of skin from those of the discoloration in Addison's disease. The chief constitutional symptoms—namely, the morbid excitement of mind and body—were also conditions totally uncharacteristic of Addison's disease; whilst the anæmia, loss of appetite, and other symptoms, which did resemble some of those of Addison's disease, were all fully accounted for by the obvious mental and physical ailments of the patient.

From this analysis of the twenty-one cases I have found published as cases of bronzing of skin without disease of the suprarenal capsules, I think it is evident that in all of them the discoloration of the skin was due to other pathological causes, and that it presented in none of them the really characteristic features of the bronzed skin of Addison's disease. I should add, what is even more important, that in none of these cases are any constitutional symptoms recorded but such as are easily referable to the morbid conditions I have mentioned as present in each. They are of course only representative cases, as others of similar characters are continually occurring, though I have not found them brought forward with reference to the question of bronzed skin and suprarenal disease.

The second allegation against the truth of Addison's discovery, viz., that disease of the suprarenal capsules not unfrequently exists without discoloration of the skin, is also, as I have said, perfectly true. Apart, however, from the small number of cases which have terminated before the development of the bronzing, it may be positively enunciated, that disease of the suprarenal capsules which is not attended with discoloration of skin, presents totally different characters from the particular lesion of those organs which I have described. Out of the thirty-seven cases which I have found published as examples of disease of the suprarenal capsules without bronzing of skin, twenty-four are cases of cancer of one or both capsules, invariably secondary to cancer of other neighbouring organs. In three of the other thirteen cases, the capsules had undergone fatty or amyloid degeneration. In one case, there was cirrhosis of the capsules, associated with kidney disease. In three cases, there were cysts; in three, apoplexy; in three, sarcomatous, fatty and plastic tumours, respectively; and, in seven cases out of the nine, only one of the two capsules was diseased. It is obvious that none of these lesions bear any resemblance to the one particular lesion of the suprarenal capsules which is attended by discoloration of skin; nor were any constitutional symptoms present in any of these

cases except such as were due to disease existing in other organs. I have myself, moreover, seen in the Middlesex Hospital several cases of cancer, in which the suprarenal capsules were involved, some of which I had had the opportunity of observing during life. The structure of the capsules was entirely destroyed in all those cases, yet in none of them had there been any constitutional symptoms or discoloration of skin resembling those of Addison's disease.

Hence, therefore, although it is quite true that bronzed skin does occur without the existence of any disease in the suprarenal capsules; and, again, that disease of the suprarenal capsules does exist, to the extent of entirely destroying their structure, without producing any bronzing of skin; it is also, on the other hand, equally clear that, in the one case, the bronzing of skin is not the peculiar discoloration indicative of the existence of Addison's disease; and that, in the other case (with the few exceptions already explained), the lesion in the suprarenal capsules is not the particular lesion of those organs which constitutes Addison's disease.

Were these the only misconceptions with regard to the relation of suprarenal disease to discoloration of skin, I might here quit this part of my subject; but, unfortunately, a small number of misunderstood cases have given a certain degree of prevalence to another opposite misapprehension, viz., that "any disease of the suprarenal capsules involving destruction of their tissues will produce the same effects as the particular lesion characteristic of Addison's disease".

Had not attention been too entirely directed to the bronzing of skin, to the neglect of the constitutional symptoms, and of Addison's original reservation that other pathological causes must first be excluded, such a misconception could never have arisen. It began, however, with Addison himself, who published four cases of cancer of the suprarenal capsules, as having been attended by some discoloration of the skin. I have also found published since his time, five cases of so-called cancer of the suprarenal capsules, and five cases of other diseases of the capsules, associated with bronzing of the skin. A glance at these fourteen cases will show that they afford no true cause for this misconception.

In the first of Addison's four cases, the patient was a woman aged 60—a time of life when the skin, even in healthy subjects, is apt to assume a dry brownish appearance; and she was suffering from extensive cancer of the left breast, lung, and surface of the liver. The only discoloration noted was a light brown swarthy hue on the face, arms, and chest. The second case was that of a woman, aged 53, who died of cancer of the stomach. She had previously had an eruption on the body; her skin was harsh, dry, and of a darkish hue; the folds of the axillæ were dark, and dark-coloured patches of the size of the palm of the hand were observed, raised in wrinkles and resembling slight ichthyosis. The third case was that of a woman, aged 28, who died of cancer of the uterus, and the only discoloration noticed was a peculiar dingy appearance of the skin, not very strongly marked. The fourth case was that of a man who died of cancer of the thorax and the lungs. When cancer was unexpectedly found in one of the suprarenal capsules, it was ascertained from the clinical notes, that the patient's face had presented a dingy hue. Addison had seen none of these cases during life, and knew nothing of their history or symptoms. Two more recent cases of cancer of the capsules, with discoloration of skin, are recorded by Drs. Gibb and Cayley. Dr. Gibb's patient had cancer of the liver and right capsule, associated with a proliferous ovarian cyst, and the only darkening of the skin observed was a brownish discoloration of the abdomen, especially below the navel; and of the chest, especially over the sternum. Dr. Cayley's case was that of a woman, aged 45, who died of cancer of the uterus, with secondary deposits in most of the abdominal organs. There was only a small nodule of cancer projecting from the surface of the suprarenal capsule; but during the last month of life the surface was very dusky and sallow, especially on the face and neck. I need scarcely point out that, in none of these six cases, was the discoloration observed in any degree characteristic of Addison's disease, and in none of them were any constitutional symptoms present, but such as were due to the disease in other organs.

The three remaining cases of so-called cancer of the capsules, with discoloration of skin, are of a very different character, having all presented, in a typical form, the constitutional symptoms and bronzing of skin described in my first lecture; and having been, in fact, as I believe, three typical cases of Addison's disease. In the first of these cases, Dr. Mettenheimer merely says, that the capsules were replaced by cancerous deposits; but he was so little clear as to the nature of such deposits, that he further reports the presence of some tuberculous or cancerous indurations of the left lung; and I think, as no cancerous disease was found in any other organ, there is no doubt that the deposits in the capsules were also of the so-called tuberculous character. Dr. Duclos, in the second case, says that the disease in the capsule was perfect scirrhus, but he had apparently made no microscopical examina-

tion, and his account of the condition of the organs is, on the contrary, a perfect description of the lesion peculiar to Addison's disease. The capsules formed tumours of the size and shape of eggs, were very hard, and much nodulated; and, on section, they grated against the scalpel and presented the appearance of lardaceous tissue. The third case, which is published by Dr. Gage of Worcester, United States, had a history which evidently led to the inference that cancer existed in the capsules, though it is not expressly asserted. The patient, a lady, aged 51, was said to have had scirrhus of the right breast, which, though of several years' growth, had not involved any of the neighbouring lymphatic glands, and had been removed two years before her death without recurrence. Her last illness was of six months' duration, and both the constitutional symptoms and the bronzing of the skin were characteristic of Addison's disease. Both the capsules were much enlarged, and joined together by a thickened mass of enlarged and diseased lymphatic glands. The right capsule was adherent to the under surface of the liver; and it is stated that from the point of attachment several broad lines of reddish-white deposit, resembling soft cancer, radiated into the substance of the liver for one inch and a half. In this case, also, there seems to have been no microscopical examination of the diseased organs; and, although the description is less clear than in the previous cases, the conviction that the disease was cancer having evidently been present to the mind of the writer, it bears on the whole a greater resemblance to Addison's disease than it does to cancer. Besides, it must be borne in mind that, if these three cases were indeed cases of cancer of the suprarenal capsules, they are the only cases on record in which cancerous disease of those organs has ever given rise to the constitutional symptoms and bronzing of the skin characteristic of Addison's disease, or has ever been attended by fatal results without the implication of other important organs—circumstances so incredible that they seem to justify the hypothesis which I have ventured to form concerning their real character.

Of the five cases of other diseases of the suprarenal capsules accompanied by discoloration of the skin, two are cases of amyloid disease. In one of these, published by Averbach, the patient, a man aged 53, presented a dirty grey brown colour of the skin, deepest on the shoulders and back, whilst the face was of a lighter hue. In the other case, recorded by Wolff, the patient had suffered for several years from a large hydatid cyst in the left kidney. A year before death, the face and forehead had assumed a dark sunburned hue, but the mucous membranes were anæmic, and the only signs of discoloration on the body were a few black spots on the neck, abdomen, and extremities. The debility, loss of appetite, vomiting, and epigastric pains, present in this case, were all, as well as the emaciation, obvious results of the general abdominal disease, and increasing discharge of fetid pus. In the remaining three cases, there was fatty degeneration of the capsules. One, related by Sir H. Thompson, was the case of an old woman, aged 81, who died of bronchitis. The skin was bronzed except on the face and hands, and the whole skin was permeated by colouring matter. In another of these cases, recorded by Charcot, the patient, a man aged 57, showed brown patches on most parts of the body, with a slight lichenoid condition of skin; the face, hands and feet remained of normal colour. The third case, published by Schet, is worthy of fuller notice, because the discoloration of the skin was, according to the description, identical with that seen in Addison's disease. It dated, however, from nine years' work under the glowing sun of a tropical climate, where the man had suffered from repeated attacks of intermittent fever, which continued at intervals during the four years he lived after returning to Europe, when he died of an epileptiform attack following copious spirit-drinking. The spleen was found to be much enlarged, and the blood contained pigment-granules and an excess of white corpuscles. The discoloration in this case, therefore, was doubtless due, in part to the effects of climate, but mainly to melanæmia, arising from malarious poisoning and enlarged spleen. It seems tolerably clear that these cases afford no real ground for the misconception that any disease of the suprarenal capsules, involving destruction to their tissues, may produce the same effects as Addison's disease of those organs.

Another misconception, nearly allied to the last, appears to exist in some quarters, to the effect that any abnormal condition of the suprarenal capsules is sufficient to raise the question of the existence of Addison's disease. Under the influence, apparently, of this misconception, a considerable number of cases have been published, in which the descriptions of the condition of the suprarenal capsules are too vague to justify any conclusions as to the nature of the lesion; whilst, in others, it seems doubtful whether there was any pathological lesion at all, and not rather some *post mortem* change. A few cases, also, of doubtful and anomalous affections of the suprarenal capsules have been published, as, for instance, one by Dr. Tuckwell, to show the necessity of caution in forming a diagnosis of such cases.

It is impossible to discuss in detail the thirty-two cases I have placed in this group; but it is certain that the characteristic features of the suprarenal lesion in Addison's disease are not described in any one of them. I must, however, advert to the most recent of these cases, published by Dr. Wickham Legg, in the last volume of the *St. Bartholomew's Hospital Reports*. The patient, a woman aged 37, unquestionably exhibited some of the constitutional symptoms of Addison's disease, for she suffered for eighteen months from debility, shortness of breath, occasional vomiting of food, and constipation, and she died after five weeks' residence in the hospital, of vomiting and exhaustion. But, on the other hand, there was a distinct bilious tendency to explain the vomiting; the appetite was fair, and there was great thirst, with a red fissured tongue, swollen spongy gums, and a temperature above the normal. Moreover, the patient had lost four stones in weight during her illness: an absolutely unprecedented circumstance in Addison's disease, unless when resulting from some serious coexisting wasting disease. The discoloured skin, also, was harsh, dry and warm, instead of being soft and cool, and was not more deeply pigmented in the axillæ or areolæ of the nipples than at other parts. At the *post mortem* examination, the right suprarenal capsule could not be found, its place being filled by a mass of yellow fat; and the left was only represented by a black body as thin as paper. This was a most peculiar and interesting condition of the suprarenal capsules, but it obviously bore no relation whatever to Addison's disease of those organs; nor were the constitutional symptoms and discoloration of skin, taken as a whole, characteristic of that disease. The most difficult point in the case is the absence of any apparent cause of illness and death.

One case remains of the whole number collected, which represents another mis-conception so remarkable, that it cannot be entirely passed over. The case is related by Dr. Gilliam of the United States, and is that of a man aged 45, who suffered from many of the constitutional symptoms of Addison's disease. Gradually increasing debility, dyspnoea and palpitation on exertion, loss of appetite, and tendency to vomiting, which became more and more obstinate until the patient died of exhaustion—were symptoms which, in the absence of any other discoverable cause might fairly lead to a diagnosis of Addison's disease, although no discoloration of skin was present. But when, after death, not only were the suprarenal capsules found to be healthy, but advanced degeneration and atrophy of the gastric tubules were discovered, which, as the author himself observed, fully accounted for all the symptoms, the diagnosis had clearly been a mistake. From this case, however, Dr. Gilliam concludes, first, that the bronzing of the skin is quite an unimportant feature of Addison's disease; and, secondly, that Addison's disease itself consists, not in a lesion of the suprarenal capsules at all, but in disease of the gastric tubules. The mis-conception lying at the root of this singular theory seems to be, that the presence of constitutional symptoms resembling those of Addison's disease was, in itself, sufficient evidence of the existence of that disease, and that the lesion which produced them might safely be regarded as the essential lesion constituting Addison's disease. That, in the case referred to, the lesion found in the stomach was the cause of the gastric and other symptoms, is obvious enough, but I trust I have made it equally clear that no symptoms, obviously referable to other morbid conditions can justify any assumption as to the existence of Addison's disease.

The question naturally arises, how mis-conceptions, so baseless in fact and disproved by such conclusive evidence, can have been so widely propagated and have survived so long. I believe this has been mainly due to the great rarity of the disease, which has prevented all but a small minority of medical men from acquiring even the degree of practical acquaintance with its true characters which the observation of a single typical case would afford.

If, however, the relation between the clinical phenomena and the specific suprarenal lesion in Addison's disease may be considered as proved, the obscure pathological processes involved in that relation, and the equally obscure causes of the suprarenal lesion itself, will still afford ample field for investigation. To these parts of the subject, I must endeavour to address myself in my next lecture, although perfectly conscious of the insurmountable difficulties they present, in the present vague and imperfect state of our knowledge with respect to many essential facts.

ACUTE GLOSSITIS IN SCARLATINA.—AN instance of this extremely rare complication has lately been published by Dr. Wm. Moore, of Dublin. It occurred in a young gentleman aged 18, and was the only example Dr. Moore had ever seen in this disease. He strongly advocates the treatment by iron and stimulants, when this complication takes place. A somewhat similar case has been described as occurring in the practice of Dr. Banks, but the complication is unusual.

THE GOULSTONIAN LECTURES ON PUERPERAL FEVER.

Delivered at the Royal College of Physicians, London.

By ROBERT J. LEE, M.D., F.R.C.P.,

Assistant Physician at the Hospital for Sick Children, Great Ormond Street.

LECTURE III.—(Continued.)

WHEN Professor Lister remarks, "We now see it is not essential to assume the existence of a special virus at all, but that organisms common to all the sores in the ward may, for aught we know, assume specific properties in the discharges long putrefying under the dressings" (*Microscopical Journal*, vol. xiii), it is clear that he is indisposed to allow that a poison apart from bacteria can be brought into existence. It is not really because these points, so difficult at present to decide, are of practical importance that I refer to them. But they are interesting, as showing pretty clearly where the various parties of investigation have started from in search of fresh knowledge. We have claimed the privilege of testing all reports thus returned by the rules of general experience, supposing there is any great difference of opinion as to their correctness. There has been little occasion, however, to do this as yet; for the most valuable contributions we have received are the results of the labours of men of practical experience in the clinical phenomena of the disease produced by septic infection. It seems to me that, for this reason, we may accept the conclusions of Virchow, Lister, Billroth, Heiberg, and others, who are quite able for themselves, and are in the habit, of applying to their researches the test of clinical experience.

There is one case, for instance, in which we might find it difficult to explain, by the theory of bacteria, certain morbid phenomena, if we confined ourselves to the limited effect which the particles produce on the tissues: those changes, namely, which we term inflammatory. It is well known that there are cases in which we find no collections of pus, or secondary abscesses, and no well marked pathological alterations, cases usually of the acute form of puerperal fever, and where the constitutional symptoms have been the chief evidence of septic infection. In such instances, morbid anatomy reveals conditions not unlike those which we meet with in certain other contagious diseases: enlargement and softening of the spleen, congestion of the mucous and serous membranes, fluid condition of the blood, and slight general congestion of the pulmonary tissue. It is in these cases that Heiberg felt a difficulty in retaining the use of the term pyæmia; for there is neither a primary focus of purulent matter, nor are there any evidences of the presence of pus in any part of the body.

This is the reason why Professor Billroth uses the term *septhæmia* to signify the resorption of septic stuff, and pyæmia the resorption of pus. We have also septicæmia contrasted with ichthæmia in some recent German works. These terms are intended to separate cases of acute septic infection from those of longer duration; for, as it is well known, in cases of abortion, retained placenta, and others, where the origin of the decomposing substance is not very doubtful, we observe a series of symptoms which lead to the belief that a slow process of poisoning is going on in the system of the patient. Such a process would be termed ichthæmic.

If we follow Professor Heiberg, as certainly we are inclined to do, on the grounds of clinical experience, we should regard these puerperal processes, in whatever form they present themselves, and whatever characters the symptoms and pathological changes may assume, as depending on one and the same cause, the action of which on the nervous system, the organs of circulation and respiration, on the temperature, and on the fluids and tissues of the body, may be modified by circumstances similar to those which we know to be capable of modifying the action of poisons generally.

For some reasons, therefore, we might feel disposed to rest satisfied with the old term putridity, which involves no such theory as septicæmia, pyæmia, and others; or we might fall back on the simple classical term sepsis as a convenient one for general use. In the clinical observation of cases in which septic agents are more or less actively at work in the system, whether in simple puerperal fever, in cases of abortion or retained placenta, in carcinoma uteri, or under any other circumstances, we are led to divide our attention between local

and constitutional symptoms; that is, between local pathological changes and general constitutional disturbance.

This evidently becomes necessary for the purposes of treatment. Allowing that the local action of septic agents is the production of those changes of tissue which we term inflammation, the question arises whether there are other causes for the same effects as well as septic material.

This question is answered by some in the following manner. "It is possible that inflammation may be excited by various causes other than the presence of bacteria; and we would distinguish the former from the latter by the term simple traumatic pyæmia and specific traumatic pyæmia, pyæmia being used in the general signification of sepsis. From simple traumatic pyæmia may follow metritis, endometritis, parametritis, perimetritis simplex, or diffuse peritonitis. In surgical cases, this disease assumes the form of erysipelatous rubor around the wound; that is to say, conditions depending on local causes. Phlebitis and thrombosis may also be consequences of simple traumatic pyæmia. The only difference between these and the specific form of pyæmia is the presence of bacteria." These are the views of Billroth, Heiberg, and others.

Now, it does not unfrequently occur that cases present themselves in which we find only those alterations of tissue which are attributed to simple traumatic causes, and yet the history and other circumstances of these cases are the same as those in specific traumatic inflammation. What must always be a difficulty appears to me to be the diagnosis between the one and the other form of inflammation. It is difficult, I think, to obtain a very clear idea of what simple traumatic inflammation is, as distinguished from the other. Does it not seem that we are defining it by negative characters; in fact, that, instead of being simple, it is a very complex expression, for it may be anything: that is, any substance or force except bacteria? If we are to call one simple in its nature, the most definite ought to have the first claim to the title. We are aware that, pathologically considered, there is no difference, as far as we can tell at present, between cellulitis or phlebitis of the thigh, as it occasionally occurs in men, or as we meet with it in the puerperal condition in women; so that, in any particular case, we are obliged to depend upon the history for information as to the origin of the disease, and upon the general symptoms for evidence of septic infection.

This is the clinical aspect which the subject presents, and, regarded in a practical point of view, it appears doubtful whether the division proposed is consistent or useful. We may have cases of metritis which have originated in abortion; but, by active treatment, the decomposition of organic matter within the uterine cavity has been prevented from infecting the system, and no symptoms are present which enable a diagnosis to be made between simple traumatic metritis and specific metritis. It may be remarked, that the difference which is assumed and appears to exist between simple and specific inflammation was present to Cullen's mind when he observed: "Whether there be any belonging to the order of phlegmasia is doubtful." (*Op. cit.*, p. 80.) In speaking of erysipelas, he remarks: "It is doubtful if this disease be properly, in nosology, separated from phlegmasia." (*Op. cit.*, p. 377.) Or, again, "It is probable that an erysipelas is sometimes attended with, or is a symptom of, a putrid fever." (*Op. cit.*, p. 379.) Looking at the question from a common sense point of view, we may reasonably ask whether there is not a danger of making confusion in our views of the symptoms, pathology, and treatment of the disease we are considering by allowing the use of an indefinite or ill-defined word like "traumatic" into the terms of definitions. It sometimes happens that we can discern the flaw in an argument or proposition without much trouble; at other times, we are withheld from consent by a feeling that, though the logical process by which the conclusion is arrived at be correct, there is a certain want of character in it which makes us hesitate. If we take the trouble to examine carefully any proposition of this kind,—and we know how frequently they present themselves to the physiologist and physician,—we shall find that there is some slight incorrectness in the premises of the argument. It is quite open to discussion whether metritis in all its forms, which are said to be traumatic, may not have been occasioned by the influence of an organic poison developed under certain conditions, or of external forces, such as cold, injury, and others. It is not difficult to perceive the direction which such reflections must give and are giving to pathological research. To return, however, to puerperal fever—a disease which, we are induced to believe, is to be explained in all respects by the influence of septic poison—it would appear that, in most cases, we are to search for the focus of decomposition in the cavity of the uterus or the surface of the mucous membranes which are connected with it. Whether we can prove that there is organic substance undergoing decomposition or not, we are to be satisfied by the symptoms which are

present that such is the case. We are also required to admit that, under several conditions, all of which involve the presence of septic substance, symptoms similar to puerperal fever may be developed; and that, whatever differences are observed in the acute or chronic character of such symptoms, we are to refer them to the rate of admission of the poison into the system. We assume that we may explain the peculiarly acute form of puerperal fever with which we are acquainted by the fact of the existence of venous sinuses in the walls of the gravid uterus, and of large lymphatic vessels by which the septic material easily enters the circulating fluids; and, when asked to define what we mean by a septic agent, by sepsis, or by any other term involving the same idea, we may make the basis of our definition the existence of active living organisms resulting from the decomposition of organic matter, having special microscopical characters, producing special effects on the system of man and beast, and the transmission of which is regulated by ascertained principles.

(To be continued.)

ON THE ACTIONS OF PICROTOXINE, AND THE ANTAGONISM BETWEEN PICROTOXINE AND CHLORAL HYDRATE.

By J. CRICHTON BROWNE, M.D., F.R.S.E.,
Medical Director of the West Riding Asylum.

THE admirable report of the Committee of the British Medical Association, appointed to investigate the antagonism of medicines, which we owe to Dr. Hughes Bennett's powers of lucid exposition, suggested to me, when reading it, various instances beyond those which received the attention of the Committee, in which a direct physiological antagonism between the actions of remedies in all probability exists. Of the conjectures which thus occurred to me, I have as yet been able to put one only to the test of actual experiment; but the results which this single investigation has afforded me are so interesting and important as to appear to me to merit early publication.

It was when perusing the description given of the effects of chloral hydrate in reducing the force and frequency of the tetanic convulsions which follow a fatal dose of strychnia, that I began to speculate that, in all likelihood, the same agent might exercise a similar influence over the somewhat analogous symptoms which follow the administration of a fatal dose of picROTOXINE. An inquiry, which I commenced some years ago, into the actions of that substance had satisfied me that, in some respects, its effects upon the living organism resemble those of strychnia. Tonic and clonic spasms of great severity and violence, culminating speedily in death, are induced by large doses of it, and opisthotonos and gasping and respiration are frequently present. The very particular in which the toxic effects of picROTOXINE differs from those of strychnia, in that they are exercised to a greater extent over the cerebral and to a less extent over the spinal centres, seemed to hold out an additional hope that chloral hydrate would effectually counteract them; for chloral hydrate powerfully diminishes the activity of the brain, and so might be expected to mitigate the influence of any agent which irritates that organ and stimulates it to excessive and irregular discharges of energy.

In proceeding to put to trial the theory thus formed as to the antagonism of picROTOXINE and chloral hydrate, it was thought desirable, in the first instance, to arrive at definite notions as to the physiological actions of the former. And these could scarcely be derived from books; for, although *cocculus Indicus*, of which picROTOXINE is the proximate principle, has been recognised as a medicine since the days of the Arabian physicians, by whom it was designated *Materadech*, its modes of operation and uses may still be said to be undetermined. Christison says of it, that it was probably first known in Europe as a means of taking fish, which it first throws into violent irregular motion and then stupefies; and that it is an active poison, adequate to occasion death, producing chiefly giddiness, staggering, tetanic convulsions and coma. He adds, that nothing is known of its medicinal properties or actions in small doses, more than that it is beneficial as an external application in scabies, ring-worm, and porrigo. Taylor intimates that it gives rise to nausea, vomiting, and gripping pains, followed by stupor and intoxication; and he describes one of the few recorded cases in which it has proved fatal, and in which these symptoms were present, and extended over a period of nineteen days. Dr. Glover describes it as a narcotico-acrid poison that acts on the spinal cord, raises the animal temperature, and causes great congestion at the base of the brain. Dr. Roebber of Berlin, who experimented with picROTOXINE,

and whose researches, published originally in the *Archiv v. Reichert und Du Bois Reymond*, 1869, are quoted in the *Journal of Anatomy and Physiology*, found that, in frogs, a comatose condition is first produced by it, and then a series of tetanic spasms, which, by and bye, become clonic. He further demonstrated that during the stage of clonic spasms, the inspirations are greatly exaggerated, so as abnormally to inflate the lungs; and that the heart's action is rendered slow, and the diastole prolonged. He alleges that the occurrence of spasms could not be prevented by the removal of the cerebrum or optic lobes, but that they never appeared after separation of the medulla oblongata from the medulla spinalis. He infers, therefore, that the spasms are dependent on stimulation of the medulla oblongata, and that the slowness and even stoppage of the heart's action, as well as the inflated condition of the lungs of the frog, are caused by this stimulant action affecting the vagus centre. To verify the observations of Koerber, and to obtain practical acquaintance with the action of picrotoxine, a few preliminary experiments were performed. In these, as in all subsequent experiments, the picrotoxine employed was obtained from one of the most trustworthy of sources, the house of Messrs. T. and H. Smith of Edinburgh, and was dissolved in ether, and administered by hypodermic injection.

Experiment I.—Rabbit weighing 2 lbs. 10 oz. One-fortieth of a grain of picrotoxine was injected under the skin of the shoulder. In four minutes, the animal was dull and lethargic. In ten minutes, it was exceedingly listless and stupid, and had lost its natural timidity, making no efforts to move when approached, touched, or pushed. It was not drowsy nor comatose, however, and its head did not droop nor nod; but it sat huddled together, its fur ruffled, and with a general aspect highly suggestive of a feeling of sickness and oppression. In twelve minutes, it voided a large quantity of urine, and its bowels acted copiously. In fifteen minutes, it was more lively, but somewhat unsteady in gait, and exhibiting stiffness and clumsiness in its movements, particularly in those of the hind limbs. In seventeen minutes, its bowels were again freely evacuated, the feces being of a rather soft and pulpy consistence. In twenty minutes, its breathing was very hurried and irregular, and there was slight shaking of the head. In four-and-twenty minutes, there were twitchings of the ears, which were held rigidly erect, and occasionally moved about in a singular jerking manner. In five-and-twenty minutes, the movements of the ears continued, and there were also munching movements of the lips, with dribbling of saliva from the mouth, which was drawn to the right. In thirty minutes, all movements had ceased, but there were considerable prostration and drowsiness; the animal lay upon its belly, with its legs stretched out as if helpless. In forty minutes, there was more liveliness. In sixty minutes, there was restlessness and uneasiness. In ninety minutes, recovery might be said to be complete.

Experiment II.—Rabbit weighing 2 lbs. 12 oz. One-twenty-fourth of a grain of picrotoxine was injected under the skin of the back. In five minutes, there were stupidity and lethargy. In seven minutes, there were a large evacuation from the bowels, and hurried and embarrassed respiration. In fifteen minutes, there was restlessness; the animal was moving about stilly, manifesting no apprehensions of the persons around, but trembling a little from time to time, especially in the hind legs. In twenty-two minutes, there were twitchings of the ears, which had a distinctly paroxysmal character. The ears were raised, and rapidly jerked about for eight or ten seconds, and then remained at rest for twenty or thirty seconds. In twenty-three minutes, there were shakings of the head and clonic spasms of the eyelids and eyebrows, causing forcible winking. In twenty-four minutes, the ear-twitching still continuing with increased severity, the head was drawn slowly and rigidly backwards, until the erect ears rested upon the back; the fore-paws were spread out, and the body was then, with convulsive starts, drawn backwards and upwards, until the fore-paws were raised in the air, and the animal sat in the position of a squirrel when eating, all its muscles, however, being agitated by clonic spasms. In a few seconds more, the animal tumbled backwards, and, the clonic spasms suddenly ceasing, it scrambled on to its feet. In twenty-six minutes, there was another convulsive seizure, like the former one, and also ending in a tumble backwards; and, in twenty-seven minutes, there was another, in which the head was drawn round to the right side, until the nose was pressed against the shoulder; the animal then turned round rapidly three times from left to right, after which all the muscles were affected by clonic spasms; these were at first coarse in character, causing sudden startings, and then fine, causing tremblings and twitchings. There was dribbling of saliva from the mouth, with incessant movements of the lips, whiskers, and cheeks; the eyeballs were drawn upwards and backwards, and were occasionally affected by nystagmus. The pupils became dilated at the close of

each fit. In twenty-eight and in twenty-eight and a half minutes, there were further seizures, and, at the close of the last, the animal fell on its left side, and was unable to regain its feet. The convulsions then became continuous. The head was thrown back, the ears were jerked about, the limbs were all extended, and worked rapidly, as in running, and there were incessant munching movements of the lips and cheeks. Peculiar murmuring noises or little short cries were emitted, and a large quantity of viscid saliva streamed from the mouth. Universal clonic spasms of this kind continued uninterruptedly for ten minutes; but their severity gradually abated. In thirty-eight minutes after the injection, there was a brief period of freedom from convulsions, and thereafter snatches of rest became more frequent and prolonged. In fifty minutes, the rabbit was lying quietly on its side in a drowsy state, broken in upon by occasional sudden irregular muscular twitchings, but giving no evidence of sensibility, or even of reflex excitability. Pinching of the tail or paws did not evoke movement of any kind. In two hours after the injection, the rabbit was still on its side, and subject to slight twitchings. Then, however, it got on to its feet, and endeavoured, in a helpless stumbling way, to move about; but, for three hours more, it was sickly and feeble, and not until five hours after the injection was it quite itself again.

Experiment III.—Rabbit weighing 3 lbs. One-quarter of a grain of picrotoxine was injected under the skin of the shoulder. In two minutes, it was sickly and frightened-looking, and its respirations were much quickened. In five minutes, it was able to move about, but was very unsteady, and dragged its hind legs after it. In seven minutes, there were quiverings of the ears, shaking of the head, and sudden startings. In nine minutes, munching movements of the mouth began; every effort at voluntary movement at once increased the twitchings of the ears and lips. In ten minutes, there were violent twitchings of the eyebrows, cheeks, and mouth, and the head was drawn first downwards, the ears at the same time becoming erect, and then backwards. At the same time, the bowels acted, and saliva began to trickle from the mouth. In eleven minutes, there was a distinct and violent convulsive seizure, characterised by sharp twitchings of the ears, drawing of the head first to the right side and then backwards, munching movements of the lips, lapping movements of the tongue, and clonic spasms of the paws, causing the animal to jump and prance upon the floor. The fit lasted twenty-five seconds, and then ended abruptly, and was followed by four other similar fits, each, however, more severe than that which preceded it. These four fits, with the intervals between them, were spread over three minutes. It was quite obvious that any attempt at voluntary movement on the part of the rabbit during the intervals between the fits at once brought on tonic and clonic spasms. At the end of the fifth fit, the rabbit, after manifesting some restlessness, suddenly sprang forward in the wildest and most precipitate manner, and ran about the room with great unsteadiness and recklessness, dashing itself against obstacles, and struggling violently. In ten seconds, however, it fell upon its side, and was strongly convulsed. The head was drawn backwards, the back formed a curve, with its concavity upwards, and the tail was raised and drawn towards the head. The ears, which felt hot, were twitched, and so were the eyebrows, eyelids, and eyeballs, the latter being drawn upwards and backwards, and oscillating a good deal. The pupils were widely dilated; the nostrils were distended; the lips were retracted, so as to expose the teeth, which were ground together; and the tongue was forcibly protruded every now and then. Large quantities of saliva, mixed with blood from the tongue, which had been bitten, flowed from the mouth. The limbs were extended, and were in incessant movement, as in vigorous running, and the toes also, with each clonic spasm, were extended and abducted. From this time, there were no distinct interparoxysmal periods; but convulsions of the kind just described continued without interruption and with extraordinary violence. In nineteen minutes, however, it was observed that the movements of the limbs were feebler, though those of the head and face were as severe as ever. The head was drawn back to the extreme possible point, and was shaking incessantly. The crunching of the teeth was loud and frequent, and the contortions of the nose and lips were unmitigated. The animal was quite unconscious; but peculiar short cries and murmuring expiratory noises were emitted from time to time, and saliva still drained away in large quantities from the mouth. The pupils were dilated to the fullest extent, and a considerable amount of a milky whitish secretion trickled from the eyelids. There was no sensibility nor reflex irritability. In twenty-two minutes, the spasms were much weaker; and, in twenty-three minutes, death took place.

Experiment IV.—Rabbit, weighing 3 lbs. 12 oz. One-fortieth of a grain of picrotoxine was injected under the skin of the back at

5.55 P.M. Normal temperature taken for 12 consecutive minutes, 103.2 deg. Fahr.

Temperature		Temperature	
6 P.M.	103.2 deg. Fahr.	6.45	100.1 deg. Fahr.
6.5	103.2	6.50	99.8
6.10	102.9	6.55	99.4
6.15	102.4	7.0	100.0
6.20	102.0	7.5	100.2
6.25	101.5	7.10	100.1
6.30	100.9	7.15	100.8
6.35	100.4	7.20	102.1
6.40	100.2		

Experiment V.—Rabbit, weighing 2 lbs. 8 ozs. One-thirtieth of a grain of picrotoxine was injected under the skin of the shoulder, at 6.54 P.M.; the normal temperature having been, by observations extending over 15 minutes, ascertained to be 102.0 deg. Fahr.

Temperature		Temperature	
6.55 P.M.	103.0 deg. Fahr.	8.5	96.9 deg. Fahr.
7.5	103.2	8.15	97.6
7.15	100.9	8.25	97.9
7.25	99.9	8.35	98.4
7.35	98.4	8.45	99.2
7.45	97.8	8.55	101.3
7.55	97.4		

Experiment VI.—Rabbit, weighing 2 lbs. 10 lbs. One-third of a grain of picrotoxine was injected under the skin of the shoulder at 3.44 P.M.; the normal temperature having been ascertained to be 99.8 deg. Fahr.

Temperature		Temperature	
3.45 P.M.	99.9 deg. Fahr.	4.5	96.6 deg. Fahr.
3.50	98.2	4.10	96.1
3.55	96.8	4.15	95.2
4.0	96.6	Death took place at 4.16 P.M.	

Experiment VII.—A terrier dog, weighing 10 lbs., had three-eighths of a grain of picrotoxine injected under the skin of the back. In eleven minutes, there were general tremor and shivering; and in twelve minutes, convulsions, ushered in by rotation of the head to the right, and twitchings of the cheeks, mouth, and fore-paws, and rapidly becoming general. The fit lasted nearly two minutes, and ended abruptly, when the head fell forwards as if the muscles of the neck had become powerless, and the breathing became stertorous. After a minute's interval, convulsions again came on with marked opisthotonos, in which the head was drawn back and the tail became erect and rigid. After four more fits, all terribly severe, and lasting each about two minutes, the convulsions became continuous, and then very soon feebler in character, while deep coma set in. The animal died just ninety-one minutes after the injection. On opening the head, the dura mater and its sinuses were found to be enormously engorged with dark blood. In the cavity of the arachnoid, was a large soft layer of dark clot covering the anterior half of the left hemisphere. All the vessels of the brain were much engorged with dark blood, as were also those of the spinal cord. The grey matter was much injected. The right side of the head was full of dark and clotted blood, and the left side was uncontracted, and contained a small quantity of dark fluid blood. The lungs were unusually pale and anæmic; and the liver was in the same condition. The bladder was empty, although no urine had been passed during the experiment. During the action of the picrotoxine, the respirations and cardiac pulsations of this dog were from time to time carefully counted, and its temperature was taken in the rectum.

TABLE I.—Showing Number of Respirations and Cardiac Pulsations and Temperature in a Dog after a Fatal Dose of Picrotoxine.

No. of minutes after injection	Condition	Re-spirations	Cardiac Pulsations	Temperature
2	Somewhat agitated	—	138	100.
8	Quiet and natural	17	66	99.7
11	General tremor	30	126	99.4
15	Much convulsed	38	164	98.1
18	Severely convulsed	—	132	98.6
20	"	—	69	98.8
22	"	36	63	99.3
28	"	18	—	99.4
33	"	18	25	99.4
43	Coma	33	—	99.4

Experiment VIII.—Guinea-pig, weighing 1 lb. 6 oz. One-fortieth of a grain of picrotoxine was injected under the skin of the back. In six

minutes, it was dull and stupid, and its respirations were much hurried. In nine minutes, there were general shuddering and quivering of the upper and anterior part of the left ear. In thirteen minutes, sharp paroxysms of general shivering continued to recur every few seconds. In nineteen minutes, it voided a large quantity of urine, and its bowels acted. In twenty-four minutes, the head was drawn to the right, there were munching movements of the right side of the mouth and right cheek, and the left paw was raised off the ground, and performed a number of rapid beating movements in the air. The fit lasted twelve seconds. In twenty-seven minutes, there was another and more severe fit, in which the head was drawn to the left, and there were violent twitchings of the face and fore-paws. Throughout the fit, consciousness was not apparently lost, and after it the animal was quite lively and well.

Experiment IX.—Guinea-pig, weighing 1 lb. 3 oz. One-thirtieth of a grain of picrotoxine was injected under the skin of the back. In eight minutes, it was drowsy, and there was quivering of the ears. In fifteen minutes, there were shakings of the head. In sixteen minutes, the head and mouth were slightly drawn to the left. In thirty-five minutes, the bowels acted, and the animal was very unsteady in its movements, stumbling as it endeavoured to walk about. In thirty-nine minutes, there was a fit. The head shook, the mouth twitched, the body was thrown first on to the left and then on to the right side, after which the animal regained its feet. By a series of jerky movements, the body was then raised, the fore-paws drawn backwards until they were off the ground, and the animal tumbled over when the fit ceased, upon which there were violent sneezing, and severe foaming at the mouth. In forty-four minutes, there was another fit, followed by repeated yawning and drowsiness. After this, there were several violent fits, accompanied by unconsciousness, incessant low cries, and copious flow of saliva, distinct nystagmus, and crunching and grinding of the teeth. Then came continuous clonic spasms, gradually becoming feebler, coma, and death sixty-two minutes after the injection.

(To be continued.)

SOME NEW RESEARCHES ON THE CAUSE AND ORIGIN OF FEVER FROM THE ACTION OF THE SEPTINOUS POISONS.*

By B. W. RICHARDSON, M.D., F.R.S.

THIS was a continuation of the author's paper read before the Society ten years ago, viz., in 1865. The author commenced his present lecture by giving a *résumé* of that which he had read in 1865. In that communication he had shown, from a series of experiments made with the serous fluids derived from a patient suffering from pyæmic fever, and under the care of Mr. Spencer Wells, that such fluid when inoculated into healthy animals, produced a distinct and fatal disease which could be transmitted to other animals through several series or generations. To the poisonous matter thus produced he had given the name of *septime*, and he had laid before the society specimens of salts obtained from the septinous matter, viz., a hydrochlorate and a sulphate, both of which possessed poisonous properties similar to those belonging to the mother liquor. He had inferred, therefore, that the poisonous substance was of an alkaloidal character. He had also, in the same paper of 1865, stated the following conclusions as the result of his experimental researches.

1. All the organic disease-producing poisons are modified, *i. e.*, poisonous secretions.
2. The secretions are rendered poisonous by two processes: (a) by contact with organic poison pre-existing; (b) by direct decomposition.
3. The poison of each secretion possesses several qualities: it can only be absorbed by particular channels, and it can only provoke farther disease by coming into contact with a secretion allied to that from which it was itself derived.
4. The reproduction of the poisons depends on the continuance of the process of physical changes in a continuous secretion. The force of secretion is the force of reproduction.
5. The poisons kill by various means: (a) by the secretion causing obstruction of necessary function; (b) by exhaustion from excessive secretion; (c) by extreme irritation of nerve and reflex injury; (d) by the absorption of the poisoned secretion into the blood and disorganisation.

From this point Dr. Richardson went on to describe that since the announcement of the facts had been put forward originally respecting septime, similar results had been obtained by Coze and Felz, Davaine,

* Abstract of a paper read at the Society of the Medical Officers of Health.

Béhier, Vulpian, and MM. Thin and Clementi. It had further been discovered by Davaine that the intensity of the poisonous matter increased in the most marked degree, and in a manner that seemed to defy computation, with the transmission of the poison through fresh series of animals.

The author now proceeded to the details of his new research, illustrating it step by step by experiment. He had put to himself the question, Why does the poisonous septinuous matter produce a definite order of morbid symptoms, and why, specially, does it produce fever? In the first parts of this inquiry he had put aside altogether the animal body, and had tried to learn what effect the poisonous substance would exert when it was brought into contact with other organic bodies of unstable composition. Would it act like ferment on saccharine substances? Would it modify the process of acetification? Would it interfere with the oxidation of readily oxidisable matters? Without entering into details that were negative, he found, he said, one affirmative fact from his experiments, upon which he should base to-night a new theory on the cause of the fever and other symptoms that occur in the living animal under the influence of septine. He found that it was the property of all the septinuous poisons to liberate oxygen from that solution of oxygen known as peroxide of hydrogen. This fact was illustrated by showing the action of minute portions of pyæmic poison, vaccine, pus, decomposing blood, and other similar bodies. The solution, which contained ten volumes of oxygen, was placed in tubes, and was inoculated with the various specimens of septinuous matter, with the effect in each case of causing a rapid evolution of the oxygen. The same result was produced by the action of fibrine on cellular tissue, but was shown to be negative with mucus, upon which fact, the author incidentally remarked, a new diagnostic test between mucus and purulent matter is established. The septinuous matter in every form seemed, from its action upon peroxide of hydrogen, to have been derived, either from fibrine or from cellular tissue, or from derivations of these bodies.

From the action of the septinuous product on oxygenised water, the author indicated their action on oxygenised blood. To a specimen of blood which had been charged with oxygen, he added solution of the peroxide to saturation. Into this he now plunged a thermometer, the bulb of which was armed with a little fibrine. Upon this oxygen began to liberate from the blood with evolution of heat, the mercury in the thermometer rising four degrees.

After adding some other experimental facts and summing up the results of all the facts he had placed before the Society, Dr. Richardson stated the theory at which he had arrived as to the effects of the septinuous matter on the living organism, with special reference to the febrile state. The theory was that the septinuous product acts upon the blood in the extreme circulation, when it has accumulated in sufficient quantity by liberating a portion of the oxygen. Upon this occur the same phenomena as had now been observed in experiment; but, as the poisonous organic product is itself destroyed in the process, the effects it produces may remit until a new charge of the poison has been produced in sufficient quantity to cause a repetition of the febrile state. Thus the theory suggested a simple reason for the remittency of fevers.

The various phases of febrile disturbance were next adverted to. It was indicated that in some instances, as in the most malignant forms of small-pox, the blood may be so charged with septinuous matter as to be unable to take in oxygen in the process of respiration, then death takes place by asphyxia after a brief period of febrile heat. In another variety of cases the liberation of the oxygen is so persistent that remission of the fever is hardly perceptible; and in other exceedingly light cases, where the quantity of poison is very small and is not reproduced, one sharp paroxysm of febrile phenomena may be all that is witnessed. In cases of abscess or of cavity in the lung this same order of phenomena may be observed in a modified degree.

The lecturer continued by showing that some chemical agents added to water charged with the peroxide solution tended to fix the combination and to neutralise the action of substances which liberate the oxygen. An experiment illustrating this fact by the action of quinine brought the lecture to a close.

OBSTETRIC MEMORANDA.

DOUBLE MONSTROSITY: MATERNAL IMPRESSION.

ON November 18th, 1874, I was called to assist Dr. Bourns of Oxford in a case of difficult labour. I found that the patient, who had borne several children without misadventure, had had labour-pains, more or less for two days; that, six hours before my visit, the head had been delivered by forceps, having been within reach, and making no progress for some hours previously; and that all the effort and power that had

been applied had been insufficient to deliver the body. The woman was tired, and full of apprehension, but her condition otherwise was not unfavourable. On placing my hand on the abdomen, I was led, from the size of the womb, to pronounce at once that there were twins. A large head and shoulders protruded from the vagina, much decomposed, livid, and with cuticle peeling off at a touch. On carrying my left hand along the child's back in the hollow of the sacrum, I felt a small foot and leg packed down between the pelvic brim and the child's pelvis; and my impression was, that the case was one of locked twin, the obstruction to delivery arising from the lower extremity of the second child having descended below the pelvis of the first. I tried to push up this leg, but unsuccessfully. Taking a firm hold of the shoulders, and using all the force of which I was capable, I could not move the child in the slightest degree. I now extended the arms above the head, wrapped them in a towel, to give a firm hold, and, whilst using powerful traction, made an effort to rotate the trunk. This was successful in moving the body, and, by continuing the force, the lower part of the body was brought down. The leg which I had felt, proved to be a supernumerary limb attached to the sacrum of the child; and, by continuing my manipulations, I was soon able to bring down the breech and two proper legs of the child. But, now it was evident that a second body sprang from the abdomen of the first; and, by a little further forcible traction, the delivery was completed. The child had one pelvis, with two well-formed lower extremities and a third smaller one attached to the sacrum, forming a tripod. Male genital organs and rectum were apparently perfect; there were a single cord and umbilicus. From the level of the umbilicus there were two distinct trunks, each with perfectly formed upper extremities and heads, well nourished and of full size. Plate 83 in Dr. Ramsbotham's *Obstetric Medicine* gives a fair idea of the monster, if a third leg be added. It was remarkable that the body of the second part was pink, and looked as though it were viable, whilst that first extruded was livid and decomposed. The cord did not pulsate; the placenta was removed without difficulty, and the uterus contracted well. When the delivery was accomplished, during which nothing had been said to give the woman a hint of what she had brought forth, I told her that she would do well, but had got a dead child, adding that it was deformed. She replied: "I thought it would not be all right; for I was frightened, at Limpsfield fair, by two men outside a show, who kept hugging each other closely and posturing. I was frightened by them, but could not keep my eyes off them." This fair happened when she was about three months pregnant. Anyone who has Ramsbotham's *Midwifery* will see at once that the figure in plate 83 resembles exactly two men hugging in a wrestling match. The mysterious subject of maternal impression has been so well handled in two good papers in the JOURNAL of February 6th, that I will add no more.

C. ROBERT THOMPSON, M.R.C.S.

CLINICAL MEMORANDA.

CASE OF POISONING BY CHLORAL HYDRATE: RECOVERY.

SHORTLY before one o'clock on the morning of February 26th, I was summoned to see a druggist's assistant, who, it was stated, had fallen down, and was totally unconscious. On my arrival, he was lying on the floor of the sitting-room adjoining the shop, quite insensible, breathing heavily, and at times almost stertorously; his face was dusky; pupils much contracted; pulse weak and about 76. He could not be roused, and he made no attempt to reply to questions put to him. I was informed that he had been out spending the evening with a friend, returned at 12.30 perfectly well, and conversed with the inmates of the house in his usual manner. He had been in the habit for some time of taking chloral hydrate; and, on leaving him alone in the sitting-room, the druggist charged him not to take any that night. On returning, however, after only three or four minutes' absence, his master found him lying on the floor in pretty much the state above described. He immediately sent for me, and not much more than twenty minutes elapsed before my arrival. A stomach-pump not being at hand, an emetic was immediately administered. He vomited freely, rousing himself at each act, and uttering some inarticulate sounds, but falling back into a more or less insensible condition. Gradually, however, the breathing improved; consciousness returned; he looked about him, answered questions, and soon after 2.30 was taken up stairs to bed. After a few hours' rest, he appeared perfectly well. He admitted having taken the chloral, and that he drank it out of the bottle used in the shop, containing a solution of the strength of a grain to a minim; and, from fear of being caught, drank it hurriedly, and took more than he intended. It is difficult to estimate the quantity that he took; but,

as an ounce and a half of the solution were gone from the bottle, and the druggist was only able to account for three drachms of it, and from the fact that drachm doses were known to have little effect on him, it would appear that the amount was considerable. He is forty-six years of age, and has been an inmate of an asylum, from which he was discharged only five weeks before. While there, he says, chloral was frequently administered to him.

STMEON SNELL, L.R.C.P.Lond., M.R.C.S.Eng., Sheffield.

THERAPEUTIC MEMORANDA.

USE OF TAR IN BRONCHIAL CATARRH.

DR. RINGER's communication, on the value of tar in bronchial catarrh and winter cough is likely to interest many others besides myself. But in seeking, at once, to prove the usefulness of the remedy, I was met by the difficulty of its administration. Tar is a liquid (in fact liquid pitch), and cannot be mixed with flour (as recommended by Dr. Garrod) even with the addition of compound tragacanth powder; and yet Dr. Ringer employs tar in two-grain doses, made into a pill, every three or four hours. Would he kindly tell us his method of doing this?

"Pitch is the altered resin resulting from the distillation of tar." Is it this which is prescribed by Dr. Ringer, and not tar?

Were the observations made by Dr. Ringer with ipecacuanha wine-spray last August published in the *BRITISH MEDICAL JOURNAL*? If not, would be very kindly explain the whole process? The quantity of wine in those who can bear it, and the intervals he advises between the applications?

R. R. CHEYNE, Nottingham Place.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

LONDON HOSPITAL.

CARCINOMA UTERI: UTERINE HÆMORRHAGE CONTROLLED BY HYPODERMIC INJECTION OF ERGOTIN.

(Under the care of Dr. HEAD.)

For the following notes we are indebted to Mr. H. T. SHAPLEY, Resident Accoucheur.

ELIZABETH S., aged 33, was admitted into Victor Ward on November 10th, 1874. She had been married fifteen years, and has been a widow for eight years. During her seven years of married life she bore five children. She first menstruated at the age of fifteen, and suffered from dysmenorrhœa until her marriage at eighteen. She enjoyed moderately good health till seventeen months ago, when considerable pain came on at her menstrual period, with profuse bleeding. Hæmorrhage had continued on and off ever since, but always worse at her periods, and was attended with sharp cutting and expulsive pains, especially referred to her right side. She had had a discharge for about the same time, but said that it had never been "particularly" foul smelling. Examination *per vaginam* revealed a very advanced malignant disease all around the cervix, and extending high up into the fundus. Her constitutional signs, also, were indicative of the character of her malady. During her stay in hospital, she had two hæmorrhages. The first followed an examination with the sound; it was not excessive, and was stopped by the introduction of ice. The next was more severe, and could not be arrested till the perchloride of iron was applied. Hæmorrhage returned on January 8th, 1875; it came on severely about seven o'clock P.M. Ice was tried, but to no purpose; plugging had not the slightest effect; the resident accoucheur was, therefore, compelled at last to swab the whole of the interior of the uterus with perchloride of iron. This took some time to arrest the flow of blood which was issuing freely from the irregular and scarcely distinguishable os. A plug of cotton-wool, saturated with solution of perchloride of iron, was left in the cervix, and the hæmorrhage ceased; since then, she had two hæmorrhages. On February 1st, the first took place, and was very profuse. The resident accoucheur injected at once two of Dr. Sansom's ergotin discs into the forearm, dissolved and introduced after his plan. (There is one-third of a grain in each disc.) No plug, ice, nor other means was employed. For the first five minutes, the quantity of blood seemed as much as before, but slowly

and surely afterwards the quantity decreased, till, at the end of half-an-hour, hæmorrhage had entirely ceased. She had not the slightest inconvenience following this treatment, neither had she the elevation of temperature (103.5 degs.) which she had after the perchloride of iron swabbing. So confident was the patient of its efficacy, that she said, "I hope, sir, that if the bleeding comes on, you will give me another of those things in the arm".

The next hæmorrhage occurred on February 17th. She had bled a little in the morning early; and, whilst the resident accoucheur was in the ward, it came on, but not so profusely as in the previous attack. This time three discs were used. They acted more quickly than on the former occasion, and hæmorrhage all stopped in about twenty minutes. No bad symptoms followed.

Her other treatment has simply been to relieve symptoms, opium and chloroform, stimulants, etc. She has had no hæmorrhage since.

BIRMINGHAM GENERAL HOSPITAL.

SYPHILOMA OF THE CEREBRAL MEMBRANES IN THE MIDDLE LINE, AND ALSO OF THE SPINAL MEMBRANES IN THE CERVICAL REGION: REPEATED EPILEPTIC AURA ON EACH SIDE OF THE BODY AT DIFFERENT TIMES; LOBULATED LIVER: ENLARGED SPLEEN.

(Under the care of Dr. RUSSELL.)

SOME points of interest are connected with the following case which may deserve a brief notice. In the first place, I may observe, in connection with the enlargement of the spleen, that the patient presented during life an anomaly which, for a short time, threw doubt upon the diagnosis: the splenic tumour was distinctly resonant on percussion, as though the intestine passed in front of it: the resonance, however, concerned only the inner portion of the tumour, leaving the outer portion dull, a circumstance which would not have happened had the colon been in front of the tumour. This resonance was correctly referred to the presence of the stomach over the enlarged spleen; though why that organ should occupy such a position, and should besides remain permanently distended, was not accounted for until we found, after death, that, through its adhesion to the liver, the stomach was tilted down over the spleen, whilst the adhesions around the pylorus rendered the free exit of flatus difficult.

I need not notice the thickened condition of the spinal membranes and their adhesion to the cord further than to point out how strikingly this portion of the disease, together with the thickening of the cranial dura mater, illustrated the local and limited character frequently observed in visceral syphilis. I may, however, ask the question whether the shivering and pain from which the patient suffered at times, and the remarkable perspirations which followed the fits, may not have been due to the disease of the spinal membrane partaking of the character of spinal epilepsy.

In remarking on the epileptic attacks (I use the word epilepsy in its widest application), I need do no more than mention Dr. Hughlings-Jackson's name as the author of the clear knowledge we possess as to the cerebral disorders which accompany foreign formations within the cranium. In the present case, we had two out of the three symptoms of cerebral tumour formulated by Dr. Jackson—severe headache and double optic neuritis. Moreover, the epileptic attacks which frequently accompany these intracranial formations often present that phenomenon known as an aura; the nature of the aura differing according to the position of the tumour, according, that is, to the arterial region within the cranium affected by it. When the tumour is seated in the region covered by the branches of the middle cerebral artery, the aura is seated in one of the limbs, of course, on the opposite side of the body, and by far most frequently in the upper extremity. In my present case, however, the attacks chiefly concerned the lower extremities; but two or three of them commenced in the left upper extremity, presenting the characteristic type, the thumb being first affected, afterwards the arm, and then the left side of the tongue and the left angle of the mouth.

It will be remarked that the intracranial growth occupied the middle line at the vertex, having much larger dimensions on the right side than on the left, but affecting both sides. Now, it is interesting to note, with this fact in view, that the fits affected each side of the body, but at different times; and that they were more frequent in the left lower extremity than in the right, corresponding to the larger size of the growth on the right hemisphere. The foreign formation on the vertex was still within the field occupied by the middle cerebral artery. We shall not fail to notice the success of the ligature in cutting short most of the fits.

The last remark which I would make is, that (as Dr. Jackson has often observed) the headache and the optic neuritis are neither of them localising symptoms; neither of them affords any information as to the

position of the tumour within the skull. In my present case, the growth was on the part of the cerebrum apparently most widely separated from the optic apparatus (on the vertex), and was equally removed from the parts of the head in which the headache was seated, the forehead and right temple.

The patient, aged 36, was admitted on May 25th, 1874, on account of diffused, deep-seated thickening, with some external enlargement, occupying the posterior and lateral regions of the upper part of the neck. This thickening was of three months' duration. During the fortnight preceding admission, a considerable amount of paralysis had attacked certain muscles of the upper extremities, with diminution of electro-muscular irritability and sensibility, but preservation of cutaneous sensibility. The paralysis was limited to particular muscles, and was evidently due to pressure on the anterior roots of certain nerves by the foreign matter deposited around the cord. During the first month of residence in hospital, the patient had frequent paroxysms of intense pain in the frontal and right temporal region; he had felt the pain for five months. There had been no vomiting. The man had had some indefinite venereal symptoms fourteen years ago, but no secondaries; and a severe attack of rheumatism seventeen years ago, lasting fifteen weeks. Iodide of potassium in full doses (twenty-five grains) procured considerable amendment; and the patient left the hospital on July 3rd, but with considerable remains of the cervical induration. He fully regained the use of his upper extremities.

The patient was readmitted on October 7th. The cervical thickening was now more consolidated; and a soft, but nearly painless, node had formed on the vertex of the cranium in the middle line.

Mr. Priestley Smith, at this period, discovered the presence of double optic neuritis. The liver and spleen were both considerably enlarged; there was extreme pallor, with subsequently (for a time) a faint lemon yellow tinge of the skin and conjunctiva, but no increase in the white corpuscles of the blood. The urine was free from albumen, and continued so; it was tested for sugar at a later period, but did not contain any. The treatment employed consisted of iodide and bromide of potassium, steel, cod-liver oil, subsequently minute doses of strychnia, with good diet; but, beyond the removal of the external node, little amendment was effected. The man progressively, but slowly, emaciated, and died January 7th of the present year.

I have now to mention some nervous symptoms of interest, presented chiefly during the second residence in hospital. Power over the lower extremities was gradually lost, though the paralysis did not become quite complete; cutaneous sensibility and electro-muscular irritability also became lessened in the lower extremities; finally, the sphincters became implicated.

Pain in the head was a less prominent symptom during the second, than it had been during the preceding, residence; but the patient suffered from repeated epileptic fits presenting a curious variety of type. Two only had occurred on the former occasion.

The most numerous attacks began with numbness or tingling over the entire left foot, not, however, selecting any particular toe (in this matter the patient was very positive), but felt most intensely on the plantar surface; a pain or sensation then ran up the leg, on some occasions along the course of the external saphenous nerve, behind the outer ankle, and, on reaching the middle of the thigh, or in some cases the trunk, the patient became insensible; the convulsions, when they occurred and could be ascertained, were bilateral. These fits, however, were generally interrupted by the ligature round the thigh, and convulsions occurred only three or four times. In other and different attacks, the right foot became cold, then the leg was "deadly cold", according to the report both of the nurse and of the patient (unfortunately, the thermometer was never employed). These attacks never ran into a fully developed fit, being always arrested by a ligature; but the coldness continued, and extended over the entire trunk, lasting for a whole night (these latter fits were very few, and occurred late in the evening), followed at length by very profuse perspirations.

Two or three times a different kind of fit took place. A tingling sensation began in the left thumb, then extended to all the fingers, and ran up the arm, extending over the trunk; last of all, it reached the left angle of the mouth and left side of the tongue; speech was never interfered with, but the patient broke out into most profuse perspirations; the sweating continued for hours, literally saturating the body, the bed-clothes, and the pillow. On one occasion, the thermometer, in the axilla, during the perspiration, registered 101 deg.

During the last two weeks of life, slight shiverings affected in paroxysms the upper part of the body; and it was then that the upper extremities first gave decided evidence of failing power. During the last two days of life, paralysis of the arms was nearly complete, and of the intercostal muscles also, with anaesthesia of the chest.

Post Mortem Examination.—The spleen weighed forty ounces, exa-

mined with the microscope, in its fresh state, by Mr. Bindley, the pathologist to the hospital; it was found free from any foreign element. The liver weighed ninety-two ounces; it presented the extremely lobulated character figured by Frerichs (Sydenham Society's Translation, vol. ii, p. 166), in his chapter on Syphilitic Disease of the Liver. Throughout its substance, bands of condensed connective tissue ran, giving it the so-called hobnail appearance. The capsule was not thickened, but the liver was generally adherent to all the surrounding organs. The condition of the stomach, resulting from its close connection with the liver, has been already described. The kidneys weighed each nine ounces; their capsule peeled off easily. In the cervical region of the spinal column, the tissues lying upon the arches of the vertebrae were found matted together and much indurated; from the atlas to the third vertebra inclusive, the membranes of the cord were matted together, and thickened nearly to the extent of one-third of an inch; the dense tissue thus formed closely surrounded the cord, and adhered so firmly to the anterior common ligament, that the knife was required to effect their separation. The interior surface of the first three vertebrae was eroded, and a small exostosis projected from the third vertebra. At the vertex, the cranial bones were deeply eroded for an extent corresponding to the diseased portion of the membrane, the erosion affecting alike the inner and the outer table. The dura mater was much thickened and very rigid along the median line, beneath the interparietal suture, for the extent of two inches and a half by one inch and a half on the right side of the falx, to a considerably less extent on the left side of the falx; the longitudinal sinus was completely obliterated in this part. A firm elastic flattened growth, of a lemon-yellow colour, divided into two lobes, grew from the inner surface of the thickened membranes on the right side, and compressed the corresponding convolutions. It commenced just half an inch behind the fissure of Rolando, and ran for two inches along the middle line of the hemisphere; the greatest thickness of the growth rather exceeded a quarter of an inch. On the left side, in the corresponding part, a similar growth existed, but of much smaller dimensions. The falx itself, the rest of the membranes, and the brain, were quite healthy.

Mr. Philip Bindley reports that the parts of the nervous centres invaded by the new growth presented the usual appearance of syphiloma. In the cord, the hyperplasia was confined to the outer layers of the dura mater; the part adjacent to the cord consisting of fibrous stroma, without any cell-elements. The cord itself was not involved. The roots of the nerves, especially the anterior, were much contorted in passing through the thickened membrane. Connective tissue-overgrowth, infiltrated with small cells and nuclei, extended through all parts of the liver, in many places being intercellular as well as interlobular. The uniformity and regularity of this overgrowth, as being universal, is worthy of note; it did not seem to have produced atrophy or destruction of the hepatic cells.

REVIEWS AND NOTICES.

A PLEA FOR THE GENERAL HOSPITAL SYSTEM. By J. M. GRANT, M.D., Deputy-Surgeon-General and Principal Medical Officer, Curragh District, 1875.

WE recently received a pamphlet entitled *The Present State of the Army Medical Service as a Life Career for the Surgeon*, and written by Dr. E. Hamilton, Vice-President of the Royal College of Surgeons of Ireland. (See the *BRITISH MEDICAL JOURNAL* of January 9th, p. 48, and, more particularly, the *JOURNAL* of January 23rd, p. 121.) In this pamphlet, Dr. Hamilton decried the system of army medical administration by general hospitals, and strongly recommended a return to the regimental system of organisation which was in vogue prior to the change made by the Warrant of March 1873. Dr. Hamilton's remarks on this head have now led to a rejoinder by Deputy-Surgeon-General Dr. GRANT, under the title which has been placed at the head of these remarks. Although the pamphlet is marked "printed for private circulation", we presume, it has been forwarded to us, that a brief notice of it may not be unacceptable.

Dr. Grant confines his remarks to the strictures which Dr. Hamilton has made in his pamphlet on the system of general hospitals in the army, and to each of these strictures he replies in succession. At the same time, Dr. Grant expresses very freely his feelings of gratitude to Dr. Hamilton for the disinterested efforts which he has made to advance the interests of the army medical officers in respect to the improvements in their pay, promotion, and retiring allowances, which he has advocated in his publication.

The first of Dr. Hamilton's allegations against the general hospital system which Dr. Grant notices is, that the status of the medical officer

has been materially damaged by breaking up the regimental system. To this Dr. Grant replies that, inasmuch as the duties and responsibilities of medical officers are the same—the difference between the two systems being only one of detail—the status of the medical officers can hardly be said to be affected by the change from one to the other; if, however, it be at all affected, then, inasmuch as the medical officers are under the command of military officers of higher rank than formerly, their military status is rather raised than lowered. Dr. Hamilton's remarks on the extravagance of a system of general hospitals is answered by an enumeration of the expenses entailed in the maintenance of a separate hospital establishment for each regiment at a station, and the contrast afforded by a general hospital calculated to meet the requirements of all. "Imagine," writes Dr. Grant, "such an arrangement adopted in our city hospitals—one set of wards being exclusively set apart to one street or district, and another to another—and the extra outlay in buildings, fuel, and attendants that would follow, will be more apparent than it seems to be to our brethren in civil life". Dr. Grant maintains, that the balance of advantage in economy, efficiency, and in comfort to the sick soldier, is all on the side of the general hospital system. When a regiment moved from its quarters, the worst cases in the regimental hospital "had always to be transferred to another hospital, and such of the sick as did accompany the regiment did so at the cost of much discomfort and very considerable risk. Regimental unity and regimental *esprit de corps* are not regarded by Dr. Grant as being of much concern to the army surgeon. "Medical officers, not having any military command, never could have any share in the military glory of their regiments, and with them *esprit de corps* should take a much wider range." On the other hand, unity in the medical service is very desirable; and, referring to the regimental system involving a division of the medical department into regimental medical officers and staff medical officers, Dr. Grant writes, "it has always appeared to me that the separation of the department into two classes, with different interests and looking to different quarters for support, has detracted from its strength and efficiency, and lowered its standing".

We have not space to notice Dr. Grant's remarks in reply to Dr. Hamilton's views on the necessity for regiments in time of war having surgeons of "their own"—not merely having a sufficient number of surgeons with them; but must conclude by quoting part of the summary which the author himself gives of the general hospital system and its advantages. "The general system," he writes, "provides for the embodiment of all the officers of the department into a corps, to be distributed throughout the districts at home and abroad, in which troops are stationed; the raising and maintaining in a state of efficiency a corps of trained hospital attendants; and the maintenance of hospitals with *fixed establishments* of medical officers and subordinates, in such number, and at such stations as the general wants of the military service may require; and its advantages to the public are, economy of hospital accommodation, fuel, and attendance; a more even distribution of medical aid to meet all contingencies during peace and war; a constant supply and sufficient reserve of trained hospital attendants, without drawing on 'the already too much attenuated British battalions' for them; saving of money and trouble in carrying about heavy and perishable hospital stores each time that a regiment changes quarters; and last, but not least, the sick remaining undisturbed in hospital when a regiment leaves a station, and their reception at all times into hospitals already in occupation, thoroughly warmed and aired, with all necessary appliances, fit for immediate use, where they can remain, with proper management, under the care of the same doctors till they are cured and fit to rejoin their regiments."

We have not adverted in the foregoing remarks to all the points on army hospital organisation to which attention is called in the pamphlet before us. We feel that those who are engaged in making a study of the subject will do well to read the pamphlet itself, and to compare for themselves the arguments adduced in it with those which have been recently circulated in the pamphlets by Surgeon-General Moutat and by Dr. Hamilton, on the same topic.

COLUMN FOR THE CURIOUS.

THE WHIPPING-POST AND DUCKING-STOOL.—The former of these two modes of punishment was in use at the beginning of the present century; the latter was discontinued about a hundred years since. The ducking- or cucking-stool was chiefly used, like the brank, to chasten scolds of the female sex. They were sometimes only exposed in it without being ducked, or the apparatus was wheeled to their doors and left there for a time. Mr. Acton will find the answer to his question in

the following quotation from the *Universal Spectator*. "Saturday, October 14th, 1738. Last week, at the Quarter Sessions at Kingston-on-Thames, an elderly woman, notorious for her vociferation, was indicted for a common scold, and the facts alleged being proved, she was sentenced to receive the old punishment of being ducked, which was accordingly executed upon her in the Thames by the proper officers, in a chair for that purpose preserved in the town; and, to prove the justice of the court's sentence upon her, on her return from the water-side, she fell upon one of her acquaintance, without provocation, with tongue, tooth, and nail, and would, had not the officers interposed, have deserved a second punishment even before she was dry from the first." The ducking-stool was also used to punish women upon the town and other notoriously bad characters.—J. H. AVELING, M.D.

AQUA VITÆ: AQUA MORTIS.—The following quaint lines on the history of alcohol well depict its disastrous effects on the human race. "Is 'aqua' alcohol? Yes; aqua fortis: '*Aqua vitæ*' once, Now '*aqua mortis*.'" In explanation of these lines, it must be stated that alcohol, when first introduced to the world in its concentrated form in the eleventh century, was invested by the imagination of men with a strange potency. Its vendors claimed for it the virtues of an elixir—of a catholicon; and physicians doled it out under the pretentious name of "*aqua vitæ*". But, passing from the shops of the apothecaries into general use, it soon earned a title to the appellation of "*aqua mortis*".

SELECTIONS FROM JOURNALS.

MIDWIFERY AND DISEASES OF WOMEN.

ELECTRICITY IN CASES OF ANTEFLEXION AND RETROFLEXION.—M. Tripiér was led to employ electricity in these cases by observing that, in a case of encysted hydrocele of the cord, the spermatic artery could be felt pulsating as long as the electric current was being applied, but not at any other time; from this he concluded that the electric current produces hyperæmia during its application. Also, since the contraction of a muscle determines the amount of its nutrition, if it can be incited to contract, its nutrition can be increased. If, therefore, it were possible to localise the electric current to one or other wall of the uterus, that part would be incited to contract, and so contract a flexion in the opposite direction. M. Tripiér has had a sound constructed with a curve corresponding to that of the sacrum. At its extremity is an olive-shaped knob, the stem being isolated. This can be passed into the rectum, and the extremity brought into contact with the posterior wall of the uterus. A similar sound, but without the sacral curve, is now passed into the uterus; and, when both sounds are connected with a battery, the current passes through the posterior wall of the uterus, causing it to contract, and thus lessening any ante-flexion that may be present. In cases of retroflexion, the second sound is passed into the bladder and placed against the anterior wall of the uterus; the result being, that retroflexion is lessened. In both cases, the uterine sound is connected with the negative pole of the battery. The pain is of two kinds: first, that caused by the sensibility of the mucous surface to the electric current, and, second, that caused by the contraction of the uterus, which is generally the more severe. M. Tripiér has never known inflammation caused by this proceeding, or the pains to persist after the circuit has been broken. At the commencement, the current should not be strong, but should gradually be increased till uterine action is aroused. As soon as this takes place, the current should be maintained at the same intensity for about three minutes. The sittings should be commenced about fifteen days after a menstrual period, and continued daily during the first month till the period. During the second month, the sittings may be less frequent. Fever contraindicates the use of electricity, as the pains are then very severe. In cases of simple congestion, relief has usually followed the second or third sitting. Absolute rest is not essential; on the contrary, exercise is beneficial to the patient, and any fatigue felt will be removed after the application of the electric current.—*Gazette Obst.*, July 5th, 1874.

THERAPEUTICS.

ACTION OF DIGITALIS ON THE EVOLUTION OF TYPHOID FEVER.—Dr. Bernheim, Professor Agrégé at the Faculty of Medicine at Nancy, publishes, in the *Memoirs of the Société de Médecine de Nancy* for 1873, his conclusions on this subject. They are as follows. 1. The thermometric evolution of typhoid fever is comprehended in the following formula, initial period from three to five days. Period of actual disease from one to two weeks, period of decline from six to

eight days. In serious cases, a second irregular period commences about the middle of the third week. 2. Digitalis, when administered in typhoid fever, always produces lowering of the temperature; either complete defervescence or remission. 3. The first effect of digitalis on the temperature shows itself two days after administration, the lowest temperature is obtained on the following day, sometimes only on the fourth day after its administration. 4. The lowering is generally progressive; sometimes it terminates by a more rapid fall. In some cases, there is a very rapid fall in the interval between two thermometric observations, from the evening to the morning, or from the morning to the evening. 5. During the action of the digitalis, the temperature may rise again in the evening, often it is equal, or inferior to that of the morning. Defervescence, or the greatest remission, may occur in the evening. 6. This defervescence, or greatest remission, lasts from a few hours to three days, the temperature then rises. In about two-thirds of the cases, it no longer rises to the same height as before the administration of the digitalis. 7. The action of digitalis on the thermometric evolution of typhoid fever may be thus expressed, the temperature is lowered. Taking into account the descent, the minimum, and the ascent, it may be said that the duration of the influence on the temperature varies from three to twelve days, the average being seven days. In two-thirds of the cases, the thermometer never reaches the original point. 8. The pulse generally falls gradually with the temperature; the temperature rarely falls before the pulse, or the pulse before the temperature. 9. It is very rarely that either the pulse or the temperature is alone influenced. 10. The pulse and the temperature fall together, but not in a parallel manner. Sometimes the pulse is lowered at night whilst the temperature still undergoes the evening exacerbation. 11. After the re-ascent of the temperature, the pulse generally remains low; it may even slacken still more, and attain its minimum several days later, even remaining slow during three weeks. 12. The lowering of the pulse varies from thirty to sixty pulsations. In the greater number of cases it falls below the normal. 13. The sphygmographic tracings undergo modifications through digitalis. Diastole between two pulsations appears on the line of descent. It rises again on that line. The pulse first becomes irregular, often reduplicate; then the line of descent becomes longer and more oblique, and tends to show a convexity above. These characteristics are explained by increase of tension and arterial tonicities. 14. Digitalis has never produced any unpleasant action on the nervous system nor on the digestive canal. The delirium often ceases or diminishes with the decrease of heat, and respiration is calmer. The intestinal hæmorrhage pointed out by Ferber as being probably produced by digitalis, does not appear in any case to have been due to this medication. 15. The fever may evolve itself with a slackened pulse. The acceleration of the heart's action is not necessary to fever, it is a secondary phenomenon which appears to be due to the augmentation of the heat itself. In the tracings of pulse and temperature taken about the beginning of an attack of fever, the thermometric tracing rises before that of the pulse. 16. The slackening of the pulse obtained by digitalis, is not the cause of the lowering of the temperature. 17. The physiological mechanism of the antipyretic action of digitalis is not explained. This action is at least partially independent of the heart and of the modifications of the arterial tension. Digitalis does not seem to act directly on organic combustion. A nerve-poison and not a blood-poison, it appears to act on the nervous system, the regulator of the animal temperature, an apparatus which, on one side, directs the waste of caloric notably by the vaso-motor nerves, and which, on the other hand, regulated the production of caloric by special ways, yet unknown, but admitted by most physiologists.

USE OF THE STOMACH PUMP.—Washing out of the stomach, and the aspiration of liquids secreted by it, is more and more practised in Germany, since Kussmaul highly praised this method. Dr. Schliep uses it in nearly all affections of the stomach, especially in chronic gastritis, with or without dilatation. The cure of chronic catarrh, according to his account in the *Deutsche Klinik*, vol. xiv, would require but a limited number of applications. In simple catarrh, five would suffice on an average. He uses this method even in the dyspepsia of consumptive patients. In dilatation of the stomach, he empties that organ with the pump every day. He performs the washing out even in cancer with pure water; or adds bicarbonate of soda to the water, if the liquids be very acid; or permanganate of potash, if these liquids show signs of fermentation; carbolic acid, when they contain vegetable parasites; boracic acid, as a disinfectant; and tincture of myrrh, in atonic dyspepsia with abundant secretion of mucus.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MARCH 27TH, 1875.

PROVIDENT INSTITUTIONS AND HOSPITALS.

I.—OUT-PATIENT DEPARTMENTS.

THE most difficult problem which presents itself to those who have earnestly studied the question of medical relief to the poor is, how to draw a line which shall, while admitting all applicants who are really deserving, rigorously exclude those who are able to pay, at any rate something, for medical attendance in the day of sickness. We propose to examine this question under various aspects, and to endeavour to show how a practical scheme of relief can be adopted by the authorities of hospitals having large out-patient departments, which shall enable them to materially diminish, or, as we believe, to entirely remove, the abuses complained of. Most hospital authorities admit that the present system of out-patient relief enables persons of all stations in life, who are mean enough to avail themselves of the opportunity it presents, to obtain skilled medical attendance, which they ought to be prevented from receiving, as they can well afford to pay for the advice their cases require. We are fully aware of the difficulties which surround this subject; and, as we are anxious to do full justice to it, we propose, while considering the question as a whole in reference to the bearing it has on the provident system, which has grown to so great an extent in the last twenty years, still to keep in mind the public and professional interests with which it is intimately associated.

We propose to give a brief outline of

1. The most important provident dispensaries, their systems of management and work;

11. The different hospitals and dispensaries which have some form of the provident scheme—working men's subscriptions, small payments for admission, Hospital Saturday collections, and so forth—associated with them;

111. The best way of utilising these means to secure a complete system of relief to all deserving cases, by which those members of the lower, middle, and upper working class who are able to pay something to their doctor, may secure the best advice without forfeiting their independence and self-respect.

All must readily agree that a working man—be he the artisan or labourer—should be taught to value highly his independence, and, to the utmost of his ability, to maintain himself and his family respectably, without the assistance of any charitable agency whatever. It is only natural, therefore, that the general public and many members of the medical profession should be strongly in favour of the provident system, because it enables the respectable poor to obtain adequate medical treatment and advice for their families and themselves, by paying weekly a certain fixed sum, which is probably less of a burden to them than the premium on a life insurance policy is to those poorer members of the upper middle class who, with equal foresight, adopt this means of providing for their families in case of death. Many members of the medical profession, however, are opposed to the establishment of provident dispensaries, because they declare that all such institutions are much abused in practice, and that those people who can best afford to pay their medical attendant liberally are usually the first to avail themselves of this means of defrauding the medical profession by obtaining their medicine and treatment for a merely nominal sum. We freely admit that at one

time we held somewhat similar views; but, after studying the subject with much care and examining thoughtfully the working of some of the largest provident dispensaries, we have come to the conclusion that, if proper precautions be taken by the managing committees to prevent abuse, objections of this kind come, in the main, to nothing. We are convinced that the profession are most anxious not to set up their interests as a class against any project which, after free and full discussion, is proved to be of vital importance to a large number of their fellow countrymen. No profession has done, or is doing, more public work without fee or reward than ours; and it is because we are convinced the gratuitous work done at the present time is far in excess of the requirements of the case, that we are anxious to see the provident principle brought into intimate connection with the working of the hospital out-patient departments throughout the country.

We believe that, if the public and the profession would calmly consider this question on its merits, their joint deliberations would result in a workable scheme, which would so sift that large class who now receive gratuitous medical relief in this country, by utilising the three great schemes which are now, as it were, working without any adequate method or control—viz., the provident dispensaries, the hospital out-patient departments, and the Poor-law medical system—that not only would the relief now given at our hospitals be reduced to reasonable proportions, but the whole country would be materially benefited in addition. At the present time, these three great schemes are practically opposed to each other, and so the mean and designing are able with impunity to make them available to as great or small an extent as they think fit. Unity of action, or a system which, while leaving the individual management of these schemes in the hands of the present authorities, would secure their harmonious working on one definite principle, would abolish imposition for ever by making it a practical impossibility.

We would warn those members of the profession who differ from us, that it is a mistaken principle to try to delay the inevitable by strenuous opposition; for, so soon as public attention is fully awakened to the abuses and anomalies of the present system of medical relief to the deserving and undeserving poor, the establishment of the provident principle in connection with the management of our medical charities will follow as a matter of course. Those who have studied this question from a truly liberal standpoint, agree that the interests of a class must never be allowed to override the welfare of the majority, and we are convinced the words of Mr. John Becke, who for thirty years has laboured in the cause of reform, and has devoted a large share of his time and attention to this subject, having during the whole of this period held the office of Honorary Secretary to the Northampton Provident Dispensary—probably the most successful in the kingdom—will meet with the hearty approval of, at any rate, many of our readers. He says:

"I quite agree that the true interests of the medical profession should always be considered by every thinking man; that anything that would tend to lower the love of that profession would be a national calamity. As a member of the community, I gratefully acknowledge the zeal and devotion they have always displayed in the care of the poor; but I unhesitatingly say that, with them as with any other profession, it is utterly impossible that their interests can be allowed to stand in opposition to the public weal. All questions affecting the public health must be discussed not with reference to the interests of any profession or class, but with reference to the good of the community."

Let us all endeavour to examine the provident system on the liberal basis here laid down, and then each of us will be able to judge it fairly and upon its merits.

There is one other point which we wish to allude to before concluding this article, and it is this. We are convinced that the philanthropic portion of the public, who give most liberally to the support of charitable institutions, are not sufficiently alive to the fact—as the Rev. Canon Millerwell put it the other day—"that there are a great many classes of working men, and it is not right to talk of working men and the poor together". It is not true that the great mass of the working men of this country are poor. Anyone who has lived in a large manufacturing district knows that the workmen not unfrequently dine off the greatest delicacies the market can

produce. People are too apt to judge by appearances, to look at the dirt and untidiness they often find in a workman's cottage, and to jump to the conclusion, from what they see, that the family are in great want, when actually they ought to be, and probably are, in receipt of high wages, enabling them to gratify all their inclinations and fancies without restraint. The working man of the present day does not regard the relief he receives at a hospital as a charitable gift at all. He not infrequently considers it his legitimate right, and will sometimes say, with some pride, and much commendable candour, that, since he contributed to "Hospital Saturday", or some similar movement, he considers himself not only entitled to receive medical advice for himself and his family at the hospital, but he further believes that his contribution entitles him to have a voice in the management of the institution also. We would not be mistaken; we would not discourage the contributions of the working man, but we would take care that he is not asked to contribute on a false principle alike injurious to the institution and to himself. Much reform is needed in the present system of hospital relief to the working classes, and we are anxious to see far less of the eleemosynary principle in the matter. The provident system does away with this abuse, and it not only secures to the working classes an independent position for themselves and their families in the time of sickness, but it enables them to provide it for themselves in a business-like way, and removes the reasonable and well founded grievance which the general practitioner has against all hospitals under the present system. Is it surprising that many thoughtful and earnest minded men are endeavouring to develop the provident system to its utmost legitimate limits, and that we are determined to aid them by all means in our power?

PYREXIA AND APYRETICS.

THE increasing use of the clinical thermometer by medical men generally, gives an importance to the subject of pyrexia, and renders a clearer comprehension of the matter than hitherto has existed eminently desirable. The mere insertion of the thermometer into the axilla of a patient, and its withdrawal after some minutes, and a reading of the temperature registered, do not constitute all that the thermometer can teach us. It is not the mere ascertaining an interesting fact, and the impression upon the mind of the patient and the surrounding friends, which should be the sole outcomes of thermometrical observation. The amount of rise of temperature is in itself certainly a matter of importance, from the effects of an increase of temperature upon the tissues of the organism. But there are other matters to be noted as well as the mere amount of the increment of body heat. In fact, the use of the thermometer necessitates an accompanying intelligence upon the part of the observer, just as much as in the case of the stethoscope. The mere increase in temperature is a barren fact, if it carry not with it a clear comprehension how that increase of temperature is arrived at. There are practical considerations associated with this question which are of much importance. It may then be desirable to consider briefly the various modes by which an increase in body heat may be attained.

Rosenthal has divided the body into an internal heat-forming zone, and an external or heat-losing surface, with an intermediate zone lying betwixt them. By the back and forward play of these two areas, the body-heat is maintained. When the surrounding temperature is low, the skin is cold, dry, and marbled. That is, there is little circulation through the skin; a small quantity of blood only is in the cutaneous area, and, consequently, little heat is lost. Not only that, but there is a corresponding increase in the bulk of blood in the internal parts—the heat-forming area; that is, there is, as far as is practicable, a diminution of heat-loss, and an increase of heat-production. On the other hand, in tropical climes, there is high vascularity of the cutaneous surface, a large bulk of blood in the heat-losing area, and a correspondingly small bulk of blood in the internal or heat-producing zone. Furthermore, as well as a large bulk of blood in the cutaneous vessels, there is the action of the sudoriparous glands with the cooling effects

of evaporation. The amount of heat rendered latent, when water assumes a gaseous form, is very large indeed, and the cooling effects of perspiration, sensible or insensible, are very pronounced. When much heat is evolved by muscular exertion, or the body is surrounded by a high temperature, free perspiration comes on; and, in the one case, dissipates the superfluous heat produced, while, in the other, it maintains the normal temperature of the body at a surrounding heat which would soon cook a corpse.

In fever, there is a disturbance of the balance normally existing betwixt the heat-forming and the heat-losing areas. This disturbance may arise in several ways. There may be an increased heat-production without corresponding heat-loss, or there may be merely diminished heat-loss. The first definite idea about fever was that of Cullen, and he attributed it to spasm of the cutaneous vessels and lessened heat-loss. This view of Cullen's has more recently received the support of Traube and of Senator. That there is diminished giving off of heat in febrile conditions, with a dry skin, is more than probable. The view of Leyden, as to the production of an increased temperature, is this—there is an increased heat-loss in fever, but there is also such an increased heat-production that there is a rise in the body-temperature. Leyden has made further observations; namely, that in increasing fever there is no evaporation of water, while the defervescence of apyrexia is accompanied by well-marked perspiration and exhalation of water; when this last is present, there is a rapid heat-loss and a fall of temperature till the norm is quickly attained. Senator also says, "The greater part of the waste of heat depends in pyrexia, as in health, upon conduction and radiation; but, in the critical defervescence, upon evaporation."

From this it would appear that there may exist a highly vascular condition of the cutaneous or heat-losing area, without any corresponding activity of the sudoriparous glands; in fact, according to Leyden, with entire loss of the insensible perspiration which normally exists. The loss of this heat-losing agent will account for the diminished dispersion of heat with a dry, burning skin, even though there be a large bulk of blood in the cutaneous area. It is, then, a matter of much importance to observe, along with the indications of the thermometer, whether the skin of the patient be moist or dry. An equal rise of temperature with a moist skin, indicates a greater increase of heat-production than the same rise with a dry skin.

There is no necessary incompatibility betwixt a pyretic condition and a moist skin. In rheumatic fever, there is notoriously a high temperature, with a skin bedewed with perspiration. In many pyretic conditions, and in puerperal conditions with accumulations of pus in the areolar tissue of the pelvis, there is usually a moist skin along with a fever-temperature.

What, then, are the practical indications furnished to us by these variations in pyretic states? For it is obvious that these different states point to different remedial measures for their relief. What the different apyretic measures are, and what are the indications for the use of each, will now engage our attention.

The measures which lower temperature are various. Our immediate forefathers were attached to venesection; and, recently, Bouchut has shown that venesection will lower the temperature of the body two or three degrees. Fresenius has found, however, that shortly it rises again; and it would appear that the effect upon the body-heat produced by bleeding should be maintained afterwards by those agents which depress the circulation, and at the same time act upon the cutaneous vessels, of which antimony and aconite are types. Such a line of practice is clearly indicated where the febrile condition embraces a bounding pulse, a strongly acting heart, and a dry skin; such conditions, in fact, as obtain in simple inflammatory fever, whether connected with any local inflammation or not. Now-a-days, no one would think of such practice in those febrile conditions mentioned above as being accompanied by a moist skin. It is in pyretic states with a dry burning skin, that those apyretic agents which induce perspiration are indicated. Here we want to restore the cooling effects of evaporation; and, for this

end, we resort to a class of agents which have recently received the term of depressants of the circulation, and which possess the double action of lowering the activity of the heart, and dilating the cutaneous vessels. By this double action, they produce a decided impression upon the production of heat. In depressing the action of the heart, they depress the circulation, and so lower the rate of chemical interchanges; while, at the same time, they increase the bulk of blood in the cutaneous or heat-losing area, and so tend to dissipate the body-heat; while they further tend to throw the sudoriparous glands into action, and to secure the cooling effects of the evaporation of water. It would appear that, in some febrile conditions, there may be a highly vascular condition of the skin without secretion in the sweat-glands, just as in the early stage of bronchitis there are high vascularity and tumidity of the bronchial lining membrane with arrested secretion. In both cases, the administration of vascular depressants induces a less turgid vascular condition, with a resumption of secretion. Of old, this end was secured by the administration of antimony in full doses, and, in the case of the dry burning skin, by the combination of antimony with opium; indeed, Hufeland regarded tartar emetic and opium, with bleeding, as the basis of all therapeutics. More recently, the use of aconite has been upon the increase; and the observations of Störck in 1763, have been corroborated by those of Fleming and Ringer, until the use of aconite in pyretic conditions may fairly be regarded as the treatment of the future in conditions of simple pyrexia. In chloral hydrate, we possess an agent which combines the properties and action secured by the union of opium and antimony. Hydrate of chloral not only affects the heart and cutaneous vessels, but it exercises no slight effect upon the nervous centres; consequently, it is highly serviceable where a pyretic condition is united to nervous excitability, and the nervous system, as well as the vascular system, needs to be calmed.

In many instances, the condition of pyrexia, associated with a dry burning skin, may be successfully alleviated by the use of the warm bath, which will often restore the arrested perspiration. There is no more efficient and yet convenient means of so acting upon the skin, than the bath proposed by the late Sir James Simpson. From its adaptability to the exigencies of the poor, it deserves description. It consists of from six to eight soda-water bottles filled with boiling water, and tightly corked; of as many woollen stockings, wrung out of hot water, each one being drawn over a soda-water bottle; and the bottles so covered being packed around the patient in bed. The moist stockings modify the heat, and convert it from dry to damp heat; so that, betwixt the heat and the moisture, the skin is thrown into action, and in from twenty minutes to half an hour free perspiration is induced, and with it increased loss of heat, and a reduction of the temperature of the body.

Such are the measures which are indicated when the pyretic condition is associated with a dry burning skin, and arrested action of the sudoriparous glands. They are not, however, the measures to be adopted when the skin is moist, while the temperature is abnormally high. Here there is already in action a decidedly pronounced heat-loss, including the effect of aqueous evaporation; and, consequently, the measures to be employed are rather those which strike directly at heat-production than those which increase heat-loss. Such agents we possess in cold, in quinine, and in digitalis. For careful and thorough investigation of the action of these agents, we are chiefly indebted to the Germans. As to the effect of cold in dispersing heat, whether given internally in the form of ice and iced fluids, or applied outwardly to the external surface, there is no question; its effect is direct and unmistakable. But, while cold is a direct disperser of accumulated heat, it does not check the production of heat. This last, it is asserted, quinine and digitalis do. Liebermeister found out, from a very large number of observations, that quinine distinctly lowered the temperature in typhoid patients. Kerner and Jürgensen found that quinine arrested the rise of temperature which ordinarily follows exercise. Wunderlich found digitalis to affect the temperature of typhoid patients. Ackermann has explained the apyretic action of quinine and

digitalis as lying in their effect upon the vaso-motor centre, and the increase of blood-pressure, which follow their administration. He states that, as the blood-pressure rose, the temperature fell. That there is a certain antagonism betwixt the amount of the blood-pressure and the temperature seems borne out by one's general experience, and that digitalis may so act as an apyretic remedy is probable enough: but that such is the explanation of the action of quinine is very questionable. The observations of Briquet and Eulenburg agree in showing that quinine produces decided lowering of the blood pressure, instead of the rise supposed by Ackermann to be the result of its administration. An elaborate series of observations and experiments by Binz, lead to the following conclusions as to the apyretic action of quinine. There is some effect produced upon the white blood-corpuscles, but Wood is of opinion that this exercises but little influence: though he says, "from the experiments of Binz himself upon the lower organisms, it would appear that quinia acts upon all animal germinal matter: and it is probable that the protoplasm of the nervous system, being more specialised than that of the white corpuscles, would be more susceptible of the influence of the alkaloid". That there is some effect exercised by quinine upon the nerve-centres which affect temperature is more than probable; though it is impossible to say what that influence exactly is. The work of Binz, however, leads one to suppose that the apyretic action of quinine lies to some extent in its checking the ozonising power of the blood. That quinine does possess an apyretic action, is unquestionable.

When, then, we meet with cases of febrile temperatures with a moist skin and distinct perspiration, the indications for treatment point to the remedies just mentioned, as preferable to the depressant and diaphoretic antipyretics. The effects of a few grains of quinine every three or four hours, especially if given along with mineral acids—the utility of which in febrile conditions is well known—is often very marked. Under such circumstances, too, alcohol is often very useful: and by means of quinine, supplemented by repeated doses of alcohol, many cases ultimately recover, which, under other circumstances, would in all probability have sunk. That they would have sunk under the use of depressant diaphoretics, is more than probable.

It is in the discrimination of the nature of each case, and the indications for treatment furnished by the observations made, that registration of temperature is so valuable in practice. But it is perfectly obvious from the foregoing, that the mere noting and registering of the patients' temperature will not give practically useful results, and that the application of the trained intelligence of the medical attendant to the clear comprehension of the how and why of the febrile state, is necessary to the selection of the appropriate remedy for the reduction of the pyretic condition.

In addition to the diagnostic aid furnished by the clinical thermometer, much information is afforded by it, when taken along with other information given by noting the condition of the skin when applying the thermometer, as to the cause of the rise of temperature; and, with that information, indications also for the proper selection of the apyretic measure suited exactly to the exigencies of each case.

THE RECOGNITION OF THE DEGREE OF MASTER IN SURGERY BY OUR HOSPITALS AND OTHER INSTITUTIONS.

OUR attention has been called by a correspondent to a very great and serious hardship to which he is subjected. He is a Master of Arts of the University of Cambridge, a Bachelor of Medicine and a Master of Surgery of the same University, and a Licentiate of the Apothecaries' Society; and he appears on the *Medical Register* with the three last named qualifications. He writes as follows:—"I apply for an appointment at a public institution, and am asked whether I am a member of the Royal College of Surgeons and a Licentiate of the Society of Apothecaries. I state that I am a Master in Surgery of the University of Cambridge, which degree gives me full power to practise as a sur-

geon. I am afterwards told that I am not eligible as a candidate because I am not a member or a Fellow of the Royal College of Surgeons. Now, of course, the authorities have a perfect right to stand by the wording of their bye-law, but, surely, are equally empowered to use it in a wider sense. Doubtless, the original intention was that the officer should be a legally qualified surgeon, and at that time the diploma of the College of Surgeons was the only one to be obtained. The requirements for the Master in Surgery from its foundation have been far greater than those for the membership." This, we need not say, is a very important matter, affecting deeply the credit, as well as the interests, of the Universities, and one which it becomes them at once to look into and to have rectified, as, indeed, it ought to have been ere this. A similar rule to that which thus bars our correspondent from the candidature for a post in the institution to which he refers, exists in the case of many other institutions: and the fact is, that at the present time a literal rendering of the rules and bye-laws excludes the University graduates from not a few surgical appointments. Even in the instance of the Poor-law service, the consultant in cases of operation must be a Member or Fellow of the College of Surgeons. Doubtless, as our correspondent remarks, there was no intention of excluding other legally qualified surgeons; but, at the time in which these laws and regulations were passed, or most of them, the College of Surgeons was the only body granting a qualification to practise in surgery. Now, however, nearly every University in the United Kingdom confers the degree of Master in Surgery after a special examination, which, in most instances, if not in all, is as good as that for the membership of the College of Surgeons; and this we say without in the least depreciating the latter. At Cambridge, the candidate for the examination must have passed the general examinations required for a degree in Arts, or nearly the same, have gone through all the curriculum, and passed the three examinations required for the degree of Bachelor of Medicine, and must have, in addition, attended lectures on anatomy and surgery, have practised dissection a second season, have attended the surgical practice of a hospital for three years, and been house-surgeon or dresser for six months. The examination for the surgical degree is, as we happen to know, an exceedingly thorough one. The examiners are selected, in part at least, from among the most eminent metropolitan surgeons. The examination is conducted in a practical manner in the dissecting-room and the hospital, as well as in writing. Indeed, the provisions, both as regards the curriculum of study and the examination for insuring competency in the graduates, can scarcely be exceeded. The regulations and provisions in the other Universities are of a similar kind. In each instance, the candidate is required to have passed the examinations required for the degree in medicine before he presents himself for the surgical examinations. It is obviously, therefore, most unjust that the graduates in surgery at our Universities should be excluded from any of those posts or offices to which the members or Fellows of the Colleges of Surgeons are admitted. All that is required is that the laws of our institutions should be brought into accordance with the present state of things in surgery and with the *Medical Register*. This ought to be done; and the sooner it is done the better. It is the duty of the Universities to see to this, and take measures that their graduates are duly cared for, and not subjected to the indignity and serious disadvantage of which our correspondent has good reason to complain.

DR. GEE has been promoted physician, and Dr. Thomas Barlow elected assistant-physician, to the Hospital for Sick Children, Great Ormond Street.

At the meeting of the Obstetrical Society to be held on Wednesday, April 7th, Mr. Spencer Wells will open a discussion "On the Relation of Puerperal Fever to Infectious Diseases and Pyæmia".

THE next quarterly meeting of the Managing Committee of the Stamford and Rutland Infirmary is to be made special for the purpose of considering a proposal to pay the medical staff for their services, which have hitherto been honorary.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AT the annual general meeting, held on March 22nd, Sir George Burrows, Bart., M.D., F.R.S., Physician in Ordinary to the Queen, was re-elected President of the College. He delivered an address, which will, at the request of the Fellows, be separately published.

THE LEWES EPIDEMIC.

THE epidemic of typhoid at Lewes, which it was hoped had almost disappeared from the town about a month ago, made its reappearance in a rather severe form during the past two or three weeks. Five or six fatal cases occurred recently. The return for the past week, however, shows a decrease both in the number of cases and the intensity of the disease.

A PROVIDENT HOSPITAL FOR BRIGHTON.

THE question of a Provident Hospital for Brighton continues to engage the attention of the medical men there, and it seems likely that this admirable proposal will be carried into effect. A correspondence on the subject has been going on in the *Sussex Daily News*, and the main questions have been well discussed. As it appears that the Sussex County Hospital is unable by its statutes to entertain the idea of opening a provident branch, the platform upon which a self-supporting hospital would have to be founded must now be well considered. There seems to be little difference of opinion as to the desirability of endeavouring to raise the tone of the working classes in the matter of medical relief. One correspondent writes:—"The quality of mercy is twice blest, it blesses him who gives and him who takes; but when I see that the working men of our country, its bone and sinew, are becoming morally emasculated, intellectually debased by misapplied charity, I am disposed to say such charity is a poison, such mercy is a curse; it curses him who gives (and unfortunately his fellow-citizens too) in the shape of poor-rates, and him who takes in the shape of pauperism and degradation. Looking at the matter thus, I would exclaim with Mr. Marriage Wallis at the Town Hall meeting, 'in the matter of medical charity, he gives twice who gives not quickly, but wisely.'" It has been a question how far the existing medical charities of the town are abused. But this, we venture to think, is rather beside the mark. It is only the gross cases of abuse which can be recognised by casual observation; and these are comparatively rare. It is for the rank and file of the industrial classes that it is necessary to devise a system of medical relief, adapted to their circumstances and to their earnings. "M.D." puts the case well when he says:

"At present, great numbers, especially of the working classes, are, in case of accident or disease, driven to the hospital because they either cannot afford or their homes are not adapted for home treatment. On such persons applying at the hospital, there is now no alternative but to admit them, but, if a provident hospital existed, the governors would be able to refer them to such an institution. I grant that a provident hospital would be impotent in reforming such abuses as now exist, if our gratuitous institutions continued to keep their doors wide open to all comers; but it is to be hoped and expected, from a knowledge of the spirit actuating influential members of their governing bodies, that a provident hospital existing and a provident dispensary existing, they would narrow their portals, and, in the interests of the working classes and of society at large, refuse to admit anyone to the benefits of the charity they dispense but 'the sick and lame poor.'"

PREVENTION OF TRICHINOUS DISEASE.

THE Prussian ministry has recently issued some modifications of the regulations made in 1865 and 1866 for the prevention of trichinous disease. One of the new regulations orders that everyone who kills a pig, or has one killed, must have it examined by an official inspector; and the flesh of the animal must not be delivered to other persons, nor prepared for human food, unless the inspector certifies that "the pig has been found free from trichinæ." An order issued in 1865 for the burial of the bodies of pigs found to be infected with trichinæ is repealed; and it is now declared that the fat of pigs, which have been found on microscopic examination to have trichinæ, may be used for technical purposes, or for food, after being boiled without the addition of sulphuric

acid. The meat, however, must be cut into small pieces, and boiled for three hours in the presence of an official inspector. The portions of flesh remaining after the removal of the fat are to be buried. An inspector of meat is not allowed to make a microscopic examination of the flesh of more than six pigs on the same day; and he must, after July 1st, make an entry of the particulars and results of his examinations in a book of forms provided for the purpose.

THE ROYAL INFIRMARY AT MANCHESTER.

AN association of local capitalists have made a proposal to purchase this institution and the ground attached to it, for a sum exceeding three quarters of a million sterling. The proposal is supported by many conversant with the merits of the question, on the sensible grounds that the hospital would be more advantageous to the general health of the patients, if it were removed into the purer air of the suburbs, than as it is now, situated in the heart of the city. A site would probably be sought in the direction of Owens College, and there would be a manifest advantage in the establishment of a clinical hospital near to the Royal School of Medicine, which now forms a part of the College. If, however, the decision of the Infirmary Board be adverse to the disturbance of the *status quo*, an extension of the present building will, in all probability, be proposed, as it is too small to meet the demands on its accommodation.

WATER-SUPPLY.

DR. T. ORME DUDFIELD, the Medical Officer of Health for Kensington, recently drew attention to a nuisance which existed in his district, similar to that which caused the outbreak of typhoid at Lewes, viz., the suction of sewer-gas through water-pipes supplied on the intermittent system. The particular nuisance has been abated; but Dr. Dudfield very truly remarks, that dangerous nuisances of the kind described may occur at any time, or in any locality, under similar circumstances, so long as the intermittent system of water-supply is maintained. Fortunately, however, in the above case, no serious epidemic occurred; but that was from good fortune rather than good judgment.

MILK CONTRACTS.

THE Guardians of St. Pancras have issued a form of contract to be signed by all persons who tender for the supply of milk for parochial use. By the form, the contractor undertakes to supply "new unskimmed milk as milked from the cow at per barn-gallon (to be of such quality as will produce at least ten parts of cream in every hundred parts, the milk to be properly tested)". The intention of this clause is, no doubt, to ensure the supply of an excellent quality of milk as milked from the cow. The provision that there shall be constantly a yield of 10 per cent. of cream is, however, so far unfortunate, inasmuch as it will not really secure that object. It frequently happens that very excellent and perfectly genuine milk sometimes will not spontaneously yield 10 per cent. of cream, although it may, by watering judiciously, be made to give the required percentage of cream. The clause, therefore, might in some cases become ineffective.

THE EXAMINATIONS AT THE COLLEGE OF SURGEONS.

DURING April, there will be two primary examinations for the membership; viz., on the 3rd and 24th of the month; and one pass examination, commencing on the 16th. The College authorities advertise that they require the schedules of candidates for the primary examination to be posted ten days beforehand; but we understand, from a demonstrator of anatomy in one of the London schools, that schedules will be accepted even up to the day of examination, provided the possible number of candidates is not completed; at the last examination in January, this was done. When the numbers were all taken, other students who applied to be examined were refused, but were told that they might apply again on the day of examination, when they would have the chance of the places of those who retired. Two or three men came from Liverpool on this chance, and then were refused. Surely this is not right. A complaint is also made of an innovation

introduced in January last by the separation of the questions in physiology from those in anatomy, on the ground that it is absurd to test a man's knowledge in physiology by two questions only. But we expect the examiners will require the experience of more than one examination to test the working of the change.

VOLUNTEER SERVICE ACCIDENT FUND SOCIETY.

THE annual meeting of this Society, which was instituted in 1862 for the purpose of affording pecuniary aid, on the principle of mutual providence, to volunteers disabled by injuries received in the performance of military duty, was held on Wednesday, March 24th. The report for 1874 showed that during the year, among 14,255 members, 102 accidents had been reported, of which 97 were admitted as claims, sums of money varying from £14 to 10s., and amounting in all to £291, being distributed among the injured persons. In the previous year, the number of accidents admitted as claims was 162, among 16,199 members; and the amount of grants £580 : 15. The allowances were made at the rate of £1 for each week of total disability. Tables given in the report showed that, during the Society's thirteen years of existence, £950 had been distributed to the widows and families of five volunteers killed by accident, and £4,343 : 10 to 1,108 volunteers who had received injuries of various degrees of severity. The following gentlemen were elected members of the Committee of Management for the next year: Colonel MacLeod of MacLeod; Lieut.-Colonel the Hon. C. H. Lindsay; Lieut.-Colonel Wilkinson; Lieut.-Colonel Stedall; Lieut.-Colonel Vickers; Major Pott; and Dr. W. Dickson, R.N., Medical Officer to H.M. Customs. We desire to call the attention of our readers, many of whom are connected with volunteer corps, to the existence of this useful Society, the object of which is consonant with that principle of providence, the development of which among the working classes we have always advocated; and to ask their aid in making it better known and appreciated than it is at present. The subscription is only one shilling yearly from each member: and from the sum raised in this way each year, allowances not exceeding £1 per week are granted. All communications regarding the Society are to be addressed to the Secretary, Dr. A. Henry, 57, Doughty Street, London, W.C.

HARVEIAN SOCIETY OF LONDON.

IN accordance with a suggestion contained in the annual address of Mr. J. R. Lane, the late President of the Harveian Society, the Council of the Society agreed to recommend that an annual lectureship should be established. At the ordinary meeting of the Society held on Thursday, the 18th instant, the proposals of the Council were unanimously adopted by the members. It was resolved that "a lectureship shall be instituted by the Society, to be entitled the Harveian Lectureship, which shall consist of either two or three lectures on some subject of practical interest in medicine, midwifery, or surgery, to be delivered annually or at the discretion of the Council. The lecturer shall be chosen by the Council from among the members of the Society, and shall receive an honorarium for each lecture". The Society rejoices in the possession of a surplus, and seems disposed to make good use of the funds which began to accumulate under the careful administration of the late treasurer, Dr. Fuller.

A BRITISH DENTAL ASSOCIATION.

THE current number of the *Monthly Review of Dental Surgery* contains a proposition for the formation of a British Dental Association, the object of which is to bring the large and constantly increasing number of members of the dental profession in the United Kingdom into more frequent and intimate relation with each other. It is proposed to assimilate the character and constitution of the Dental Association to those of the British Medical Association. The General Council would be in London, and made up both of provincial and London practitioners. Branches would be established in various centres throughout the kingdom, having an organisation of their own for all local pur-

poses. An annual session, lasting three or four days, would be held once a year; and it is suggested that they should be held at the same time and in the same town as the session of the British Medical Association. For obvious reasons, the President would be elected from the town in which the British Dental Association met. Further details of the scheme will be found in the periodical already referred to.

DR. RUMSEY, F.R.S.

WE desire to call attention to the report of the meeting held by some of the friends of Dr. Rumsey of Cheltenham, under the presidency of Dr. Farr, on Tuesday last. The great services rendered by Dr. Rumsey to Public Health are too well known to need recapitulation, and are a striking example of what may be achieved by a country practitioner, unaided by official position, but having enlightened conviction combined with unwearied industry, ability, and perseverance. On the British Medical Association, the labours of Dr. Rumsey give him a peculiar claim; he utilised its organisation in the fullest and most practical manner; and it will always remain a lasting credit to the Association, that to it, largely in consequence of Dr. Rumsey's impulse and under his direction, through the State Medicine Committee, the country is indebted for the sanitary measures which have distinguished the parliamentary legislation of the last few years. It is, therefore, we think, incumbent on the Hon. Secretaries of the various Branches of the British Medical Association to bestir themselves heartily in support of the resolutions passed at the meeting at Somerset House, and thus to give substantial proofs of their recognition of Dr. Rumsey's life-long services in the cause of State and Sanitary Medicine. He has spent himself in the service of the country. Such work as he has done cannot be achieved without the constant sacrifice of personal interests. Hence we look in vain at this moment for any to succeed him even in the least difficult part of his work, the vigilant and suggestive criticism of sanitary measures. His mind, however, was always not less constructive than critical. His withdrawal from public life is an immeasurable loss. His enthusiasm, his experience, his earnest and single-minded devotion to sanitary progress inspired others, who will greatly miss the influence, and missing it, may shrink from the tasks to which he encouraged them. Fortunately for the cause of Public Health, his activity endured over the most critical periods of legislation, and his untiring energy has left upon the statute-book monuments of his word. But this is distinctly not the work which pays in coin. Mothers have a distrust of the physic of philosophers. Work such as Dr. Rumsey's reflects honour on his profession, adds to its knowledge and its influence and credit in the State, and its power of usefulness. But it is the reverse of lucrative. It has its own dignity, its own rewards, its own nobility; but it carries pains and penalties, and in this case a sudden infirmity has aggravated and increased them. In carrying out the resolutions of the meeting to which we refer, and bringing them under notice in their Branches, the Local Secretaries will fulfil what may almost be considered a moral obligation.

THE LUNACY LAW.

IN the course of comments on the case of Miss Wood, we observe complaints that the existing Lunacy Law is in an unsatisfactory condition. An arrest under the present order and certificates ought, it is said, to have only a provisional effect, and no lunatic ought to be permanently imprisoned without a certificate from a medical officer of the Government. But this is exactly what now takes place: every patient is visited by a medical officer of the Government, to wit, a commissioner in lunacy; he can demand a private interview, and will be discharged if found sane. No one is "permanently imprisoned" without such inspection, but if, as some suggest, every patient is to be inspected by a commissioner immediately after admission, commissioners will have to be appointed by the hundred, for the admissions amount to many thousands; and we question whether the taxpayer would approve of the arrangement.

THE LIVERPOOL ROYAL INFIRMARY.

OUR Liverpool correspondent announces the completion of the enlarged operating theatre, which is now as commodious, well lighted, and otherwise suitably appointed, as could well be desired; at the same time, a new and much enlarged dead-house and *post mortem* room have been added to the infirmary, with all necessary adjuncts for teaching and demonstrating morbid anatomy and practical pathology. These additions are but the commencement of considerable improvements contemplated by the Committee, with a view to develop to the utmost the facilities this large hospital affords as a school of medicine and surgery. Amongst other arrangements in perspective, the intern medical staff is about to be increased by the appointment of six house-surgeons, who will be selected by competition from the students of the school on the completion of their curriculum, and after having obtained a qualification. These and other suggestions which the progress and rapidly increasing requirements of the Medical School have forced upon the somewhat too conservative leaning of the Infirmary Committee, are most encouraging and satisfactory to those who take an interest in the advancement of medical education in general, and of provincial medical schools in particular.

REJECTED CANDIDATES AT THE COLLEGE OF SURGEONS.

FOR the last year or two, the Council of the College of Surgeons has published a return of the number of rejected candidates at the primary and pass examinations for the diploma of membership, from all the recognised schools. Being desirous of extending the usefulness of this return, Mr. John Gay brought forward the following motion for discussion at a recent meeting of the Council. "That a report from the Court of Examiners be annually laid before this Council at the quarterly meeting in July, of the number of candidates who have presented themselves during the year for the professional examinations for the diploma of fellow, showing the number who have passed and have been rejected from each medical school in the period; and that a similar report from the Court of the number of those passed and rejected during the past collegiate year (1873-74) be laid before this Council at the earliest convenient opportunity." This proposal, however, failed from want of a seconder.

THE LEAMINGTON PROVIDENT DISPENSARY.

THIS institution has just held its sixth annual meeting, and we are glad to observe that it continues to make steady progress. The number of cases treated during the year was 3,776, as against 3,698 in 1874; and the sum divided among the three medical officers was £379 : 15 : 10, as against £336 : 6 : 3 in the previous year. Lord Leigh, who presided at the meeting, in his opening speech, said: "He could hardly conceive a more useful institution than a self-supporting provident dispensary. There was an old saying, which would bear repeating, that charity could not be more effectually shown than by helping those who endeavoured to help themselves. He was proud to say that Warwickshire was one of the first counties to adopt provident dispensaries. The Coventry dispensary was founded by the philanthropy of one who had now been dead many years, the late Mr. Smith of Southam, who was assisted in the good work by several friends; and some few years afterwards a similar institution was started at Warwick, and was still being successfully carried on there. When they heard that there were 3,385 members, and that during the last six years and a half 20,000 cases had been treated in connection with the Leamington Dispensary, these figures alone spoke volumes for the success of the institution. He hoped sincerely that the institution would continue to progress and flourish, as he was satisfied of this, that the more self-supporting dispensaries were adopted throughout the country, the greater would be the benefit to poor people."

RECENT URBAN MORTALITY.

DURING last week 3,791 births and 4,194 deaths were registered in London, and twenty other large towns of the United Kingdom. The annual rate of mortality was 28. It was 25 in Edinburgh, 35 in Glas-

gow, and 29 in Dublin. In the eighteen large English towns the rate was lowest (23) in Leicester, whilst in Norwich it was 31, Sunderland 31, Liverpool 31, Manchester 33, Nottingham 36, Oldham 36, and Wolverhampton 37. The zymotic rate was 6.0 in Oldham, and 6.9 in Sunderland. Scarlet fever continues somewhat fatally prevalent in Bradford and Hull, and the deaths from measles have steadily increased in recent weeks. In London, 2,518 births and 1,728 deaths were registered. The births exceeded the average by 26, and the deaths by 80. The annual death rate was 26. The deaths referred to zymotic diseases were 180; were 56 below the average; and gave a zymotic rate of 2.7. The deaths referred to diseases of the respiratory organs, which in the two previous weeks had been 612 and 566, declined to 498, but exceeded the average by 103. Of persons, aged eighty years and upwards, 59 died during the week. In outer London the death rate from all causes and from the seven principal zymotic diseases was 19.5 and 1.8 per 1,000 respectively, against 26.2 and 2.7 in inner London. At Greenwich the mean reading of the barometer was 30.05 inches: the mean temperature of the air was 37.0 deg. or 4.5 deg. below the average; and the general direction of the wind was north and north-east. Rain fell on Friday only, to the amount of .10 of an inch.

EPSOM COLLEGE.

THE authorities of the College have decided that for the future there shall be three terms, each of thirteen weeks' duration. The Christmas vacation, which formerly lasted four weeks and a half, is now restricted to four weeks; whilst the summer vacation, which used to extend over six, is now prolonged to seven weeks. The Easter vacation remains as it was, viz., a fortnight in length. In accordance with the new arrangements, the Easter vacation for this year will begin on Friday, April 16th.

SCOTLAND.

EDINBURGH ROYAL INFIRMARY: MODE OF ELECTION OF MANAGERS.

A SPECIAL general meeting of the Court of Contributors to the Royal Infirmary was held last week, for the purpose of making "a bye-law to regulate the mode of election of six managers by the contributors on the first Monday of January yearly". This course was rendered necessary by the troublesome discussions which took place at the election meeting at the beginning of the present year, when, it will be remembered, the ruling of the Chairman as to the proper mode of election was so disapproved of by a section of the meeting, that it was at one time thought probable that the law-courts would be applied to. Fortunately, pacific counsels prevailed, and the present meeting was intended to prevent similar difficulties in future. The chair was occupied by the Lord Provost; and the meeting, which was not a large one, unanimously passed the following rules: "That the name of any person proposed as a manager must be lodged with the Clerk of the Infirmary a week before the meeting; that all names so lodged shall be publicly advertised; that a printed list of persons so proposed shall be handed to members of the Court of Contributors as they enter the room; that, when a poll is demanded, the voting shall be by crosses opposite the names of the nominees it is desired to elect; that not more than six names shall be so marked; that the slips shall be collected by tellers, and the result reported to an adjourned meeting of contributors; and that it shall not be competent to propose any person whose name has not been lodged with the Clerk a week before, except with the unanimous approval of the contributors present at the meeting." These rules, it will be hoped, will prove satisfactory. At the same meeting, it was mentioned that the average cost of each patient in the Infirmary has risen within the last few years from £35 to upwards of £50, and that increased subscriptions were urgently needed to meet the additional outlay. To help in raising subscriptions, the work of canvassing has for the past two years been taken vigorously in hand by some ladies and gentlemen, with the result of a considerable

increase. Now that the work has been again handed over to the paid officials, the Committee trusted that the newly acquired subscribers would not fall off.

ROYAL MEDICAL SOCIETY OF EDINBURGH.

THE annual dinner of the Royal Medical Society was held in the Douglas Hotel a week or two ago, and, as usual, was a successful and pleasant gathering. Dr. Saundby, the senior President, was in the chair, and was supported by several of the Professors, the Presidents of the Royal Colleges, Dr. Matthews Duncan, Dr. Gairdner of Glasgow, etc. The Chairman, in proposing the toast of the evening, "Success to the Royal Medical Society", pointed out that the Society continued to be as prosperous as ever, and that the number of members was increasing, in spite of the great demands now made upon the time of medical students.

ROYAL SOCIETY OF EDINBURGH: THE MAKDOUGALL-BRISBANE PRIZES.

AT the last meeting of the Royal Society of Edinburgh, Professor Crum Brown, on the part of the Council, stated shortly the grounds on which they had awarded the Makdougall-Brisbane prize and gold medal for the biennial period 1872-74 to Professor Lister for his paper on the Germ-Theory of Putrefaction and other Fermentative Changes. It was important as a contribution to microscopic botany: as a great step towards settling the question, "Do living beings ever arise from putrescent matter?" as to its chemical bearings, especially in regard to fermentation; and as to the bearing of the observations as the basis of the system of antiseptic surgery. The President then presented the medal to Professor Lister, and expressed the hope that he would continue his important researches.

DEATH OF PROFESSOR INGLIS OF ABERDEEN.

THE news of the death of Professor Andrew Inglis of Aberdeen was received in Edinburgh with general regret, where he was well known as an able obstetrician, and greatly esteemed by a large circle of private friends. He commenced practice in Edinburgh in 1860, and in 1867 became one of the lecturers in midwifery in connection with the Extra-Academical School of Medicine. Shortly afterwards, in 1869, he was appointed to the Chair of Midwifery in Aberdeen. Two years ago, however, his health broke down under an overstrain of anxiety and fatigue, and he was compelled to apply for leave of absence from the Senatus for two years, which he obtained. He was a good deal improved in general health until a short time since, when he was seized with an attack of congestion of the lungs, to which he succumbed in a few days.

THREATENED BURNING OF THE UNIVERSITY.

THE University buildings and the Museum of Science and Art were in no little danger of being destroyed by fire last Sunday week. The South Minster Music Hall, a building of wood, which stood near them, caught fire, and the wind blew quantities of burning wood and cinders in their direction. Owing principally to the exertions of Professors Turner and MacLagan and a number of students, the danger was averted from the College by a hose being carried to the roof, and a stream of water being kept in readiness to extinguish any burning masses. The lantern roof of glass and wood of the Museum presented an even more favourable place for a conflagration, and Mr. Archer and his assistants were kept hard at work for upwards of an hour in running water along the gutters where the burning wood had alighted. No damage was done to either building.

UNIVERSITY OF EDINBURGH.

AT a recent meeting of the University Court, leave of absence in the early part of next summer session was given to Professor Lister, for the purpose of visiting foreign schools during the session; and arrangements under which the class of Clinical Surgery is to be taught by Mr. Chiene, Assistant-Surgeon to the Royal Infirmary and Lecturer on

Surgery, were approved. The following University examiners were selected to conduct the examinations for graduation in science in the Department of Public Health: *First Examination*, Chemistry, Professor Crum Brown; Physics and Engineering, Professor Fleeming Jenkin; Sanitary Laws and Vital Statistics, Professor MacLagan; *Second Examination*, Medicine and Practical Sanitation, Professors MacLagan, Laycock, and Sanders.

DR. CHADWICK DE BANZIE.

"DR." CHADWICK DE BANZIE, who appealed last week from the decision of the Sheriff to the Court of Sessions against a conviction for illegally practising, was successful in his appeal, on the ground that, the charge against him being general and including more than one statutory offence, the conviction did not shew specifically of which offence or offences the appellant had been convicted.

IRELAND.

AT the annual meeting of the members of the Royal Irish Academy held last week, Professor William Stokes, M.D., D.C.L., F.R.S., was appointed president for the ensuing year.

ON the 18th instant, the appointment of medical officer to Kilmalham Gaol was filled up by the selection of Dr. Kirkpatrick out of a large number of candidates.

AT a meeting last week of the Belfast Guardians, it was resolved that a superannuation allowance of £50 *per annum* should be allowed to Dr. Henry M. Johnston, late visiting medical officer of the workhouse.

DURING the last quarter of the year, the birth-rate in Ireland amounted to 24.4 in every 1,000, and the death-rate to 17 per 1,000, the latter being somewhat beyond the average of preceding years, and the higher mortality being due to the prevalence of scarlet fever and to the inclement weather.

DUBLIN HOSPITAL SUNDAY.

OUR readers may remember that three institutions in Dublin, viz., the Meath and Adelaide Hospitals and the Hospital for Incurables, refused to co-operate with this movement, and declined to receive any portion of the funds collected. We learn that the Meath Hospital will join the movement this year, but regret that the Adelaide Hospital should still stand aloof. The advisers of the latter institution, in our opinion, are acting most injudiciously, and we sincerely trust that before it is too late better counsels may prevail as regards this matter.

ROYAL COLLEGE OF SURGEONS OF IRELAND.

A MEETING of the Council was held on the 18th instant, in reference to the appointment of a professor of chemistry, including practical chemistry, in the room of Dr. Reynolds, resigned. The following members of the Council being selected by lot to make the appointment—viz., John K. Barton, William Colles, Henry G. Croly, Michael H. Stapleton, William Stokes, Edward Ledwich, Albert J. Walsh. The candidates were three in number: Charles A. Cameron, City Analyst, and Lecturer on Chemistry in the Ledwich School of Medicine; Edmund William Davy, Professor of Medical Jurisprudence to the College; and Emil Königs: Dr. Cameron, as was all along expected, being successful.

MEDICAL OFFICERS FOR BELFAST.

AT a meeting of the Committee of the Belfast Dispensary District held last week, Dr. Wilberforce Arnold moved, "That, in view of the facts disclosed in the reports of Mr. O'Brien, Government Board Inspector, regarding the exceedingly onerous duties of the several medical officers, and the amount of duty discharged by them, it is imperative that additional medical officers be appointed for the Belfast Poor-law District".

In support of this motion, Dr. Arnold referred to the additional duties imposed by the Vaccination and Registration and Sanitary Acts upon the medical officers, whose number had not been increased since it was fixed twenty years ago. The modern methods also of investigating disease by the aid of chemical tests, the microscope, the stethoscope, the ophthalmoscope, and the clinical thermometer, require considerable time for their proper application; and Dr. Arnold very properly contended that the sick poor are as justly entitled to the benefit of these aids to diagnosis as any other class or society. Dr. Arnold also pointed out that, within the last few years, three out of the six dispensary doctors had died, it was believed, victims to overwork. The motion was, however, negatived, on the ground that only one of the medical staff had made any complaint of overwork, and had then refused an offer to relieve him of a portion of his district for reasons connected with his practice. It was also suggested by one of the Committee that, if the medical staff had any reason to complain, they now had an excellent opportunity to resign their posts. This, however, is an extreme measure, which most medical men would hesitate before taking, even if they had considerable grievances. It might, perhaps, be as well if these grievances were taken into consideration before forcing them to such a step. Besides, even from an economical point of view, it is a well demonstrated fact that to treat the sick poor thoroughly well is to keep their families off the rates, and thus to spare the pockets of the ratepayers. This aspect of the matter may yet recommend itself to the Dispensary Committee of Belfast, and eventually result in the appointment of the needed increase in the dispensary staff of that city.

DR. MONKS.

We regret extremely to hear that Dr. Monks of Dublin, who, our readers may remember, was injured in a railway accident in England some time since, is suffering so much from the effect of his injuries, that it will necessitate his retirement from the practice of his profession.

THE INTERNATIONAL MEDICAL CONGRESS AT BRUSSELS, 1875.

THE fourth Session of the periodical International Congress of Medical Science will commence at Brussels on September 19th, 1875, and will last a week. It will be composed of those native and foreign medical men who send in their names to the Committee, and who alone will have the right of taking part in the discussions. The only expense incurred by members will be 12½ francs (10s. 6d.) for a copy of the Report of the Proceedings of the Session. A card of admission will be forwarded with the receipt for this subscription. Applications for admission are to be made on and after July 1st; and members' names will be forwarded and cards of membership distributed on the afternoon of September 18th and the morning of the 19th. Members must have their names put down in the section to which they desire to belong. A member may belong to several sections. The Congress will meet twice daily; in the morning for the work of the sections, in the afternoon for general meetings, which will be devoted to conferences on questions of general medical interest not included in the programme, and to reading the reports of the sections and discussion of their contents. Members wishing to read papers on any subject not included in the programme, must give notice to the Committee at least a month before the opening of the Congress. No one will be allowed to speak more than twenty minutes; this restriction, however, does not extend to the sectional reporters. All papers read at the Congress must be left at the Committee room for publication at the discretion of the Committee. The proceedings will generally be conducted in the French language, but foreign members will be allowed to express themselves in their native tongue. If wished, the sense of their discourses will be briefly interpreted to the meeting. The Committee consists of M. Vleminckx, President; and MM. Deroubaix, Bellefroid, and Crocq, members; with M. Warlomont, General Secretary, to whom all communications relating to the Congress should be addressed. The programme of the Congress is as follows. 1. *Medicine* (comprising Pathology, Pathological Anatomy, and Therapeutics); the Prophylaxis of Cholera; Alcohol in Therapeutics; the Inoculability of Tubercle. 2. *Surgery* (comprising Military Surgery and Syphilography); on Surgical Anæsthesia; and the Dressing of Wounds after Operation. 3. *Obstetrics* (including Diseases of Women and

Children): Lying-in Hospitals. 4. *Biological Science* (comprising Anatomy, Physiology, Comparative Medicine): the Vaso-Motor Nerves and their Mode of Action; the Value of Experiments based on Artificial Circulation. 5. *Public Medicine* (comprising Hygiene, Forensic Medicine, Medical Statistics): the means of making Workshops in which Phosphorus is manipulated healthy; the Organisation of the Public Health Service; the Manufacture of Beer. 6. *Ophthalmology*: Defects of Vision in relation to the Military Service. 7. *Otology*: the means of Measuring Hearing and Registering in a uniform manner in all Countries; Defects of Hearing in relation to the Military Service. 8. *Pharmacology*: Should the Medical Employment of Chemically defined Principles immediately be extended, and should the Preparations of them be Multiplied in the Pharmacopœias? the establishment of an Universal Pharmacopœia.

DR. RUMSEY, F.R.S.

At a meeting of the friends of Dr. Henry W. Rumsey, of Cheltenham, held at the General Register Office, Somerset House, on Tuesday last, Dr. Farr in the chair, the following resolutions were carried unanimously.

1. Proposed by Dr. A. P. Stewart, and seconded by Dr. G. Buchanan, That considering the distinguished services rendered, during forty years, by Dr. Henry W. Rumsey to the cause of sanitary science and state medicine, the instruction accruing to the medical profession, and the advantages to the public at large from his self-sacrificing labours, and in view of the recent attack of paralysis which has incapacitated him from continuing the practice of his profession, it is desirable that some substantial token of public and professional gratitude should now be presented to him.

2. Proposed by Dr. Sibson, F.R.S., seconded by R. B. Grantham, Esq. (Institute of Civil Engineers), That a subscription list be opened for the above purpose, and that the general public, as well as the medical profession, be appealed to.

3. Proposed by John Simon, Esq., F.R.S., and seconded by Captain W. Clode, That a memorial, setting forth the particulars of Dr. Rumsey's career and the strong claim which he has thereby established to a national recognition of his services, be presented to the Prime Minister, praying that a pension should be granted to him out of the Civil List.

It was then resolved, that those present, with others who have sent in their names, should form a committee to carry out the above objects, and that they should invite Dr. Rumsey's friends and admirers to join them.

Dr. Farr, F.R.S., was elected chairman of the committee, Dr. G. Buchanan treasurer, Dr. Corfield secretary, and Mr. Rendle, of the General Register Office, assistant secretary.

Subscriptions to the fund should be sent to Messrs. Roberts, Lubbock, and Co., bankers, to be placed to the account of the "Rumsey Testimonial Fund".

THE SOCIAL POSITION OF OUT-PATIENTS.

A FORTNIGHT ago we gave extracts from a report upon the social position of the out-patients at the Royal Free Hospital, which has recently been printed by the Charity Organisation Society. The inquiry was undertaken at the request of the hospital authorities, and is highly creditable to them. If a few other hospitals and dispensaries—some general and some special—would institute similar investigations, valuable statistics would be obtained, which would supply the data, upon which a well-devised and practicable scheme might be based for the reform of our medical charities. As it is, the information contained in this report goes far to establish the need of such reforms. We have always contended that the gross and flagrant cases of abuse, which are sometimes used to point the moral of a speech, though they undoubtedly occur, are yet comparatively few. What we have often insisted upon is, that the hospitals and dispensaries are to a great extent resorted to by the well-to-do artisans, and that it is for this class more especially that some alteration is needed in the mode of administering medical charity. Both these points are fully borne out by the report. Of the 641 cases which were investigated, 172 were set aside because they had given either false addresses, or insufficient information. Of the remaining 469, only twelve were considered to be in a position to pay a private doctor. Though this number may at first sight appear small, yet it must be remembered that it represents 2½ per cent. of the cases that were classified; and it is not too much to infer that the proportion would have been at least as great in those who gave false addresses. If we are justified in assuming that this percentage may be taken as fairly representing the average amount of gross abuse at the general

hospitals, the total figure would amount to a very serious evil. Out of every 20,000 out-patients there would be 500 who ought to be employing general practitioners; and how small a number is 20,000 compared with the total number of the out-patients at the general hospitals of the metropolis!

But great as this evil is, the report has demonstrated another which, if not so flagrant, is of far wider extent. It has shown that a proportion of 49 per cent. though "unable to pay even the lowest scale of a general practitioner's charges, are well able to contribute a small amount towards the cost of their own treatment". When we call to mind the large number that were set aside for giving false addresses, and at the same time notice that the report tells us that the investigators were studiously moderate in assigning cases to the various classes, we may safely say, for convenience of reckoning, that one-half of all the out-patients at the general hospitals could pay 6s. a year, on the provident system, towards the expense of their own medical attendance; and how large a sum again does this represent abstracted from the earnings of the profession!

Perhaps it may be argued that the Royal Free is not a fair example of the general hospitals, because it requires no Governors' letters of recommendation. There may be some force in this objection. But, after all, a subscriber's letter is only too easily obtained, and offers but a very slender barrier against abuse. While, on the other hand, it must be remembered that the Royal Free has not the prestige of the older foundations, and is not backed by a medical school: both of which circumstances add to the attractions of the other large general hospitals.

It must be borne in mind that the inferences we have drawn from this report refer only to general hospitals. Probably the case would be much stronger if an investigation were undertaken at one of the special hospitals: and any such institution which would set on foot a similar inquiry, would add a most important supplement to the information furnished by this report.

Though, as the report very properly remarks, it is beyond the scope of the instructions from the Committee to suggest alterations in the mode of conducting the hospital, yet a hint is given of the path in which, in the opinion of the investigators, reforms ought to advance. "If," they say, "a provident branch could be established, or if a provident dispensary could be affiliated to the hospital, this would very materially facilitate the better regulation of out-door medical relief. A large proportion of the applicants for out-patient relief might then be rejected, or rather referred, without the least appearance of harshness. Any such institution ought to be self-supporting. It should be served by the out-patient staff of the hospital, and a great part of the members' payments should go to form a fund from which the medical officers should receive an honorarium for their services." This suggestion is not so novel as it may appear to some of our readers. The plan here recommended was adopted six years ago by the Royal Albert Hospital, Devonport, and has proved remarkably successful.

We must not omit to draw special attention to the opinion expressed by those who conducted the investigation, that "the whole body of the out-patients is really divisible into two sections. (1) Those who might reasonably be expected to pay something for their medical relief, and (2) those who ought to be referred to the parish." We lately expressed a similar conviction ourselves, and we are glad to find it endorsed by such high authority as the Charity Organisation Society.

The report, as a whole, is the most important paper that has appeared for a long time upon the much debated question of hospital abuse. It is the first systematic investigation, upon a large scale, that has ever been attempted in the out-patient department of any Metropolitan Hospital. The Managing Committee of the Royal Free deserve great credit for the courage and candour which they have manifested in thus submitting their institution to a public inquiry. They have shown an admirable liberality in listening, with an unprejudiced ear, to the voice of public opinion, and have adopted the best means of satisfying themselves of its correctness, so far as their own institution was concerned. Whatever conclusion they may draw from the facts stated in the report, and whatever action they may think proper to take in consequence, we feel sure they will reap their reward in an increased measure of public confidence.

THE Duke of Devonshire has been elected President of the Chesterfield and North Derbyshire Hospital and Dispensary. His Grace has presented a large case of books for the use of the patients.

DR. WILLIAM R. WARWICK has been presented with a clock and side ornaments, an inkstand of solid silver, and an illuminated address, by the subscription of his friends and patients, on the occasion of his leaving Southenl, Essex, to reside at Brixton.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

March 14th, 1875.

Copper in the Human Organism.—Ferments or Fermentation.—Germs.—The School of Medicine.—Professor Pajet.—Retirement of M. H. Roger.

IN my last, which appeared in the journal of February 27th, I gave a short account of the results arrived at by MM. Bergeron and L'Hôte in their researches as to the quantity of copper that exists normally in the human organism. This quantity was estimated to be somewhat less than two milligrammes, or 3-100ths of a grain; but in the bodies of the deceased wives of the famous Moreau of St. Denis, the above-named experts found in the liver of one of them a hundred and twenty milligrammes, and, in the liver of the other, only eighty milligrammes.

MM. Bourneville and Yvon have since read before the Academy of Sciences a paper touching the same subject. Investigations have been carried on conjointly by these gentlemen in M. Charcot's ward at the Salpêtrière, where a certain number of epileptics were submitted to treatment by the ammoniated sulphate of copper, one of whom was carried off by tuberculosis. It was stated that this patient had had none of the medicine for three months before her death, as it had been suspended, the salt not having produced the desired effect. The liver of this patient was submitted to chemical analysis, and the following conclusions were given by the authors of the paper as the result of their investigations.

1. The ammoniated sulphate of copper, far from reducing the epileptic fits, increased their number. The quantity of the salt administered daily was gradually increased from ten to fifty centigrammes (about one and a half to seven and a half grains). The only accidents noticed were; 1. Vomiting, consisting sometimes of alimentary substances, and, at others, of a glairy fluid of the colour of verdigris, which attracted the attention of the other patients; 2. Colicky pains and diarrhoea, which, however, were of a temporary character.

II. At the *post mortem* examination, nothing was to be seen in the stomach or intestines that could be attributed to the action of the sulphate of copper.

III. The chemical analysis of the liver showed that this organ contained as much as 295 milligrammes of metallic copper, which would correspond to one gramme and sixteen centigrammes of the sulphate of that metal. This quantity is considered enormous, particularly as the medicine had been suspended for three months before the death of the patient, during which time a certain proportion must have been eliminated. Thus it may be seen that, in the case under notice, the quantity of copper found in the body is more than double that found in the bodies of the poisoned subjects referred to.

The question of ferments or fermentation germs is still being discussed at both the Academies. At the Academy of Medicine, M. Colin, professor of Veterinary Medicine at the Ecole d'Alfort has taken up the subject, and disposes of M. Pasteur's theory in a most summary manner. M. Colin's arguments are to the effect that putrefaction may and does take place without the intervention of germs or other inferior organisms, and he produces, as an example, an ordinary fowl's egg, through the shell of which no germs can penetrate, as, according to M. Pasteur's own showing, a little cotton-wool is sufficient to keep them out. Moreover, in examining a rotten egg, M. Colin detected certain bodies which resembled not real living beings, but simple albuminous corpuscles: from which he inferred that putrefaction is not due to organisms produced by spontaneous generation. And, from all this, M. Colin concludes that putrefaction is the result of chemical action which takes place without the necessary intervention of inferior beings, or without homogeneity or heterogeneity. In the open air, however, or in ordinary condition, the lower organisms play a certain part in the process of putrefaction. They live on the products of the putrid decomposition, which are favourable for their existence; they modify them after the manner of acari, the larvæ of insects, worms, cryptogams, which are mere passive agents in the process of putrefaction; in other words, they are simple spectators, beneficiaries, and not actors.

The winter session at the School of Medicine has just come to a close, and that for the summer begins on the 15th instant. The following is a list of the professors who are to lecture during the coming session: Professor Baillon, Medical Natural History; Professor Becard, Physiology; Professor Charcot, Pathological Anatomy; Professor Trelat, Surgical Pathology; Dr. Bergeron, acting for Professor Tardieu, Legal

Medicine or Medical Jurisprudence; Professor Regnauld, Pharmacologie; Professor Pajot, Midwifery and Diseases of Women and Children; Professor Vulpian, Experimental and Comparative Pathology; Professor Hardy, Medical Pathology; Professor Bouchardat, Hygiene; Professor Gubler, Therapeutics and Materia Medica. Clinical Medicine: Dr. Hayem, acting for Professor Bouillaud, Charité Hospital; Professor G. Sée, Charité Hospital; Professor Béhier, Hôtel Dieu; Professor Lasègue, La Pitié. Clinical Surgery: Professor Richet, Hôtel Dieu; Professor Gosselin, La Charité; Professor Verneuil, La Pitié; Professor Broca, L'Hôpital des Cliniques. Clinical Obstetrics: Professor Depaul, L'Hôpital des Cliniques. Supplementary Lectures: Diseases of Children: Dr. Blachez, Hôpital des Enfants; Ophthalmology: Dr. Panas, Lariboisière; Syphilitic Affections: Dr. Fournier, Lourcine Hospital.

You will observe from the above list that Professor Pajot, who has been prevented by over-fatigue from lecturing for the last two years, is to resume his functions at the School of Medicine, much to the gratification of the medical students, among whom he is a great favourite.

The inexorable law of age has removed from the office of hospital physician the highly esteemed and well-known "children's doctor" M. Henri Roger, he having completed his 66th year. He was for many years physician to the Children's Hospital in Paris, and is succeeded by Dr. Blachez.

ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the office of the Association, 36, Great Queen Street, Lincoln's Inn Fields, London, on Thursday, the 15th day of April next, at two o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary*.

36, Great Queen Street, London, W.C., March 18th, 1875.

METROPOLITAN COUNTIES BRANCH.

A GENERAL Meeting of this Branch will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Friday, April 16th, at 8 P.M.; when a discussion will be opened by Mr. HOLTHOUSE on the subject of Legislation for Habitual Drunkards.

ALEXANDER HENRY, M.D. } *Hon.*
ROBERT FARQUHARSON, M.D. } *Secs.*

BATH AND BRISTOL BRANCH.

THE Fifth Ordinary Meeting of the Session will be held at the Royal Hotel, College Green, Bristol, on Thursday evening, April 1st, at half-past seven o'clock: F. MASON, Esq., President.

Bristol.

EDMUND T. BOARD, *Hon. Sec.*

SOUTH-EASTERN BRANCH: EAST SUSSEX DISTRICT.

THE first meeting of the above district for the present year will be held on Wednesday, March 31st, at Terry's Restaurant (opposite the South-Eastern Railway Station), Tunbridge Wells, at 3 o'clock P.M.; BLACKALL MARSACK, Esq., in the Chair.

Dinner will be provided at 5 P.M., charge 6s., exclusive of wine.

All members of the South-Eastern Branch are entitled to attend these meetings, and to introduce professional friends.

The following communications are expected.

1. Mr. Marsack: Supposed Case of Vegetable Poisoning; Two Cases of Malignant Pustule.
2. Dr. Johnson: Case of Locomotor Ataxy; Case of Thoracic Myalgia.
3. Mr. T. F. Sanger: On Malaria.
4. Mr. W. Wallis: Case of Poisoning by Oil of Tobacco.
5. Two papers by Mr. G. F. Hodgson, of Brighton, President of the Branch.

THOS. TROTTER, M.D., *Hon. Sec.*

35, Marina, St. Leonard's-on-Sea, March 16th, 1875.

SOUTH-EASTERN BRANCH: EAST SURREY DISTRICT.

A MEETING was held on March 11th, 1875, at the Crystal Palace Hotel; E. R. RAY, Esq., in the Chair.

Next Meeting.—It was agreed that the next meeting should be held

at Reigate, on October 14th, 1875; and that J. Sisson Steele, Esq., be requested to take the Chair.

Secretary.—Dr. Galton was re-elected Secretary.

Puerperal Convulsions.—Dr. GALABIN read a paper on the causation of puerperal convulsions. A discussion ensued, in which Mr. Stilwell, Mr. Eccles, Dr. Mansfield, Dr. Galton, and others, took part.

Cystic Degeneration of the Chorion.—Mr. ECCLES exhibited a specimen. The case occurred in a primipara. Menstruation ceased in July; a fright happened in September; in November, the first bloody discharge appeared. In January, the patient was seen. She presented an uterus of apparently three months' pregnancy, with patulous os. The mass, of ovoid shape, burst before passing; three days after which, there was large secretion of milk from the breasts. Mr. Stilwell and Dr. Ogilvie made observations on the case.

Recovery from Tubercular Peritonitis with Cerebral Symptoms.—Dr. DALTON read a case which occurred in a child aged 10. Sub-acute ulceration of the bowels was followed by abdominal tenderness and pain, with fluid in the abdomen. There was inequality of the pupils, the right being larger; strabismus; twitching of left arm and leg; intolerance of light and sound. Pulse 100, temperature 100. For twenty days, cerebral symptoms continued, with screaming at night, etc. The case was treated with iodide and bromide of potassium, with complete recovery. A few months afterwards, a distinct hard lump was to be felt in the abdomen, to the left of the umbilicus. The father died of rapid breaking up of pneumonic consolidation at the upper lobe of the lung, and the brothers suffered from enlarged glands, etc.—A discussion followed, in which Dr. Miller (who thought it probable that typhoid fever might account for the symptoms), Dr. Galton, Mr. Stilwell, Dr. Galabin, Mr. Ray, and Dr. Dixon, joined.

Cardiac Rheumatism.—Dr. MILLER read notes of a case occurring in a patient aged 23, without any joint-affection. On December 22nd, he had urethral discharge; on January 7th, general pains, with pulse 84; tumultuous heart-action; normal area of precordial dulness; double friction-sound, with mitral systolic murmur; no perspiration or acid smell. In the progress of the case, the temperature was 102 deg., and distinct acid sweat occurred. The mitral systolic murmur was persistent. He considered the case to be one of a class, as we constantly find cases of heart-disease with no history of previous rheumatism or scarlet fever.

Acute Endocarditis.—Dr. GALTON read a case of acute endocarditis, seen from its commencement, in a boy aged 8, in which there was no joint-affection or rise of temperature throughout. Dr. Mansfield and Mr. Stilwell made remarks on the case.

The interest of the meeting was increased by an excellent collection of surgical and other instruments exhibited by Messrs. Millikin of St. Thomas Street.

Dinner.—Fourteen members and three visitors sat down to dinner.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 23RD, 1875.

Sir JAMES PAGET, Bart., F.R.S., D.C.L., LL.D., in the Chair.

A CASE OF PULSATING TUMOUR OF THE LEFT ORBIT, CONSEQUENT UPON A FRACTURE OF THE BASE OF THE SKULL, CURED BY LIGATURE OF THE LEFT COMMON CAROTID ARTERY, SUBSEQUENTLY TO INJECTION OF PERCHLORIDE OF IRON, AFTER DIGITAL COMPRESSION AND OTHER MEANS OF TREATMENT HAD FAILED; WITH REMARKS AND AN APPENDIX CONTAINING A CHRONOLOGICAL TABLE, AND A RÉSUMÉ OF THE RECORDED CASES OF INTRAORBITAL ANEURISM. BY WALTER RIVINGTON, M.S. LOND., F.R.C.S.E.

THE author prefaced the narrative of the case with an historical *résumé* of the views and observations placed on record by previous writers. The first known case was described by Mr. Travers, in 1809, as a case of aneurism by anastomosis, and the second by Mr. Dalrymple in 1812, under the same designation. Notwithstanding the observation of Guthrie, in 1823, of a case in which similar symptoms existing on both sides were shown by *post mortem* evidence to have resulted from an aneurism of each ophthalmic artery within the orbit, the views of Travers were generally adopted for many years, as explanatory at least of the idiopathic cases of intraorbital aneurism. Mr. Busk, in 1835, met with a case which arose gradually after a fracture of the base of the skull, and was able to cite the prior case of a boy, under the care

of Mr. Scott, in 1834, at the London Hospital, in which protrusion and pulsation of the eyeball supervened after an injury to the head, occasioned by a fall into a ship's hold, and in which the subsequent occurrence of violent arterial hemorrhage from the nose rendered it necessary for Mr. Scott to ligature the carotid; a cure resulting. Mr. Busk combated the views of Travers, and advocated the view that his own case, and previous ones had been cases of ordinary aneurism affecting the ophthalmic artery within the orbit. His paper had a marked influence on subsequent observers, as might be judged from the fact that M. Pétrequin, Mr. Curling, M. Bourguet, M. Legouest, Mr. Zachariah Laurence, M. Gioppi, Dr. Morton, and Dr. Schmid of Odessa, all diagnosed their cases as examples of aneurism of the ophthalmic artery; whilst M. Demarquay, Mr. Nunneley, Mr. Jos. Bell, Mr. Ernest Hart, Dr. Delens, Mr. Holmes, and others who had ably and successfully opposed the view of Travers, had repeated, with reinforcements of their own, Mr. Busk's arguments. To Mr. Nunneley was due the chief credit of first directing forcibly the attention of pathologists in England away from the orbit to the vessels lying behind it; and he showed from *post mortem* observations in two out of six cases which he had met with, that the symptoms might be due to an aneurismal affection of the internal carotid artery in the cavernous sinus, or an aneurism of the ophthalmic artery within the skull. The record of Mr. Bowman's well-known case, by Mr. Hulke, in which no change was found in the arteries, but in which the cavernous, transverse, and petrosal sinuses were obstructed by clot; and M. Aubry's case of obliterated inferior petrosal sinus; and MM. Wecker and Richet's fatal case, were all so many indications that aneurisms within the orbit were only exceptional conditions. A brilliant light had been thrown on the pathology of the traumatic cases, by the publication of two cases under M. Nélaton, in which all the symptoms had resulted from a direct communication between the internal carotid artery and the cavernous sinus produced by the fracture of the base of the skull; and a similar case observed by M. Hirschfeld. These cases, and cases of spontaneous rupture of an aneurismal carotid, related by M. Baron, in 1835, and M. Gendrin in 1841, were little known in this country until the publication of Dr. Delens' monograph, and Mr. Holmes's lectures at the College of Surgeons. The author's own case was briefly this. W. C., aged 24, was admitted into the London Hospital in July 1873, with a fracture of the skull. Six weeks later, the patient heard a noise in his head, like wind blowing; the eye gradually became prominent, pulsation of the eyeball was seen for a day or two, followed by the formation of a pulsating and thrilling tumour between the eye and the margin of the orbit. There was a *bruit*, continuous, with reinforcements, and the *bruit de plement* could be heard at intervals. At the time of the commencement of the aneurismal symptoms, Mr. Reeves was in charge of Mr. Rivington's wards, and carried out very thoroughly digital compression, without making any impression on the disease. Ligature of the carotid was discussed, but negatived at a consultation. A further trial of compression, digital, instrumental, and direct, having been made without effect, combined with veratrum, and the affection at the end of a year being decidedly aggravated, threatening extinction of vision and preventing work, an injection of five drops of a neutral watery solution of the perchloride was made; but, this proving to be insufficient in quantity to cause sufficient coagulation in the dilated ophthalmic vein, and a second injection being impracticable, on account of subsequent swelling, the carotid artery was tied by Mr. Rivington, and effected a cure of the disease; a slight *bruit* only remained, but superficial ulceration of the cornea occurred a few days after ligature, and resulted in opacity. The author then discussed at length the causation, symptoms, pathology, differential diagnosis, and treatment of the affection, the following being a few of his conclusions. 1. Of 62 recorded cases, 29 were idiopathic, and 33 traumatic; of the 29 idiopathic cases, 11 were affected on the left side, and 13 on the right; whilst of 33 traumatic cases, 22 were affected on the left side, and nine on the right, the side affected not being mentioned in the others. Thus, the preponderance of cases in which the affection had existed on the right side was entirely maintained by the traumatic cases. 2. Pulsation of the eyeball and a pulsating tumour might be absent, but no case should be regarded as one of so-called intraorbital aneurism unless, in addition to exophthalmos and chemosis, a *bruit* were present. 3. The only true basis for the pathology of intraorbital aneurism was the record of *post mortem* examinations, to which allusion had been already made. By this the doctrine of aneurism by anastomosis had been negatived, and a variety of morbid conditions had been disclosed (*vide supra*). 4. It was of great importance to recollect that, in eight out of twelve cases examined after death, the ophthalmic vein had been found varicose and enlarged, and in four certainly had formed the pulsating tumour observed during life at the orbital margin. The distension of veins might reach to the bridge of

the nose and the forehead. After specifying the distinctive features of erectile tumours of the orbit, pulsating encephaloid cancer, sphenoidal meningocele, and rejecting as efficient causes of the affection arterio-venous aneurism of the orbit, cirrroid aneurism, and aneurism by anastomosis within the orbit, and morbid conditions of the sympathetic nerves and ganglia, the author pointed out the necessity of studying the mode of occurrence of the symptoms, the nature of the paralytic symptoms of orbital muscles (if present), the character of the *bruit* and pulsating tumour, and other points, for the purpose of forming an opinion as to the pathological cause of the affection in any given case. Having discussed the means of treatment, and given the statistical results, the author showed that the symptoms might return in three different ways; that loss of vision might occur in cases treated by any method, or not treated at all, the result depending chiefly on the degree of interference with the circulation by the formation of coagula before anastomosing channels could be established. The conclusions as to treatment were the following. 1. Belladonna, digitalis, veratrum, and ice were worthy of a trial; 2. Digital compression should always be essayed; 3. Instrumental compression was more difficult, and more likely to injure important nerves; 4. Galvano-puncture was not well suited for application to a thin-walled vein; 5. Coagulating fluids were adapted only for cases of arterio-venous aneurisms; 6. Ligature of the carotid was the remedy most generally applicable, but should not be hastily employed. The author expressed his obligations to Mr. Holmes for his interest in the case and supply of valuable information.

MR. HENRY POWER said that the affection was a very rare one. Among 15,000 or 20,000 patients in ophthalmic practice, he did not remember to have seen one case; and the late Sir William Lawrence, in his work on the eye, did not mention that he had seen one. He doubted whether the forms described could be distinguished accurately from each other. With regard to treatment, he thought the injection of perchloride of iron dangerous, and would prefer the ligature. He showed a drawing of a nevus of the eyelid in an infant, which had begun to extend backwards into the orbit, and which he had treated successfully by a figure-of-eight ligature.—MR. HULKE said that the value of the paper would be more perceptible when it was in print. Mr. Rivington had spoken of aneurism by anastomosis. This term had been used in different senses; William Hunter applied it to arterio-venous aneurism. With regard to the question of the formation of erectile nevus in the orbit, he would call Mr. Rivington's attention to a case described by von Gräfe some years ago, in which an encapsulated cavernous tumour was found in the orbit; also to a similar case recorded by Mr. Critchett. As to the *bruit*, he doubted whether its tone was of any value; but it was important to observe whether it was continuous or interrupted. From what he had seen and read, he regarded injection of perchloride of iron as a proceeding fraught with the gravest risk, unless the communications with vessels around could be cut off. He had heard of a case where the injection of a few drops of solution of perchloride of iron into a nevus over the sternum was followed by death; and of two other cases (one of which, he believed, died), in which extensive sloughing took place.—MR. CURLING agreed with Mr. Power that the malady was very rare. The author had collected his materials from very various sources extending over a long period of time, and had found only sixty-two cases. Still it was important that surgeons should know something of the subject, lest they might meet with cases. As to treatment, he would speak of traumatic cases, and in these he regarded the early application of the ligature as of importance where vision was seriously threatened. He would not even wait to see what effects might be produced by digital compression. In idiopathic cases, where there was no indication of injury, digital compression and other measures might be tried before resorting to ligature.—DR. C. J. B. WILLIAMS desired to call attention to the medical aspect of the subject. The disease described in many instances closely resembled exophthalmic goitre. He believed that in all such cases there was an enlargement of the carotid arteries, extending to the arteries at the back of the eye, and sometimes accompanied by a murmur. Usually there was also enlargement of the thyroid, from enlargement of its vessels. The cases seemed to belong to a diseased condition that had scarcely received sufficient attention; viz., partial enlargement of arteries. There was often at the same time an anæmic state of the system. He thought that, in such cases, medical treatment, applied early, was quite as successful as surgical. As he had said on a former occasion, "the physician's iron was better than the surgeon's steel"; and cases of the kind were readily amenable to the internal use of perchloride of iron, with strychnia, digitalis, good living, etc. His remarks, of course, were not applicable to traumatic aneurisms of the orbit.—MR. W. ADAMS called attention to Prava's experiments on the injection of perchloride of iron; he had found that one drop was sufficient to coagulate one drachm of blood. The solution of perchloride of

iron contained free hydrochloric acid; and this, if it escaped into the cellular tissue, would produce serious destruction of the parts. He briefly related a case in which he had injected perchloride of iron into the tibial artery of a child.—Mr. HULKE said that, some years ago, he had injected two drops of solution of perchloride of iron into the vein over the tendo Achillis in dogs, by Pravaz's plan: the result was instantaneous death; extensive coagula were found in the veins.—Mr. C. HEATH had seen a case where a *bruit* was heard, and a ligature applied to the common carotid artery: after death, no aneurismal state of the arteries was found. Another case of the same kind had been referred to by Mr. Rivington; and, if two cases had occurred, could it be inferred that there had been aneurism in all the successful cases?—The PRESIDENT had never seen a case of pulsating tumour in the orbit; but he would point out that any tumour deeply set in bone would commonly pulsate, even though it had no blood-vessels, receiving an impulse from the vessels, however small, in the neighbourhood. This might be noticed in tumours of the antrum. Pulsation, perceptible to the eye, was also communicated to the pus in cases of necrosis. In the same way, he considered, increased pulsation of the ophthalmic artery from any cause would be followed by a communication of the pulsatile movements to the eye.—Mr. RIVINGTON having replied, the Society adjourned.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, MARCH 3RD, 1875.

W. O. PRIESTLEY, M.D., F.R.C.P., President, in the Chair.

Clinical Notes on the Early Course of Cancer of the Cervix Uteri.—Dr. CHARLES LIEBMAN read a paper on this subject. After quoting the opinions of many authors, he narrated the particulars of four cases observed by himself, in which he showed that the disease generally spreads much higher in the lining membrane of the cervical cavity than in the exterior part of the neck. Amputation of the neck he considered useless in all cases of cancer, excepting those of the pedunculated canceroid papillary tumours of the cervix.—Dr. WILTSHIRE thought the "beginning of cancer" of singular importance to the profession as a matter of clinical as well as of pathological interest. It involved an important practical point; for it was obvious that, if we could find out the beginning of the disease, and were thus enabled to treat early the implicated tissues, we might at least have the satisfaction of arresting the disease, and that sometimes for a considerable period. Dr. Wiltshire mentioned two cases in illustration of his remarks. In both, considerable benefit followed removal of such portions of the diseased tissues as could readily be attained. He had sometimes used chromic acid with considerable success.—Dr. HEYWOOD SMITH remarked on the far greater frequency of cancer in the lips of the uterus than the fundus or body. He had tried Dr. Gibb's method of treatment, with plugs of strong perchloride of iron, and in a large proportion had seen, with some arrest of discharge, grave symptoms supervene, symptoms as of septicæmia. He laid stress on the rule on which Dr. Barnes had insisted viz., that in all cases, when practicable, early removal should be had recourse to.—The PRESIDENT remarked that Dr. Liebman had drawn attention to an interesting pathological subject. The object of his paper was to point out that authorities generally regarded the vaginal portion of the cervix as the seat of the beginning of cancer, whatever its form might be, but that he had observed cases in which the disease commenced in the cervical cavity, and he had been able to demonstrate the development of masses of epithelioma in that locality, while the external labia were entirely unaffected. The author, however, did not seem to be conversant with the researches of Virchow and other pathologists, who had observed cancer originating both in the mucous membrane of the cervix and body of the womb, and had demonstrated the development of canceroid in the uterine walls themselves. Cancer beginning first in the fundus uteri was not uncommon. Sir James Simpson had written a paper on the subject, and he believed instances had been published by Dr. Barnes and others. He had in recollection more than one case where he had watched the progress of malignant disease in the body and fundus of the uterus, and where ulceration had made its way into the peritoneal cavity, with the cervix to all appearances scarcely at all involved. The difficulty of diagnosis in cases of cancer of the interior of the uterus was no doubt very great, and he knew no way of distinguishing a malignant growth situated in the fundus from the enlargement of a benign character, except by observing the nature of the discharges, the comparatively rapid growth, and the persistent pain associated with the former. In the treatment of epithelioma or other malignant disease of the cervix, he believed that there was a general concurrence of opinion that, when the tumour had a margin of healthy tissue above, it was desirable to amputate the cervix, but he

had not yet made up his mind whether in worse cases, viz., when the disease had advanced above the line of demarcation between the cervix and body of the uterus, and it was not possible to remove the whole morbid growth, it was desirable, by operative procedure, to remove a considerable portion by way of staying the progress and lessening the discharges. He thought this might be justifiable where the discharges and loss of blood were great and rapidly reducing the patient; but where the symptoms were less urgent, his experience rather indicated abstinence from interference, as any but palliative measures had seemed to give an impetus to progress, and to lead to more rapid development of the disease.—Dr. ROGERS thought the paper was useful to the Society, if only to elicit the opinion of the Fellows. He considered it impossible to cure cancer by means of escharotics, though of these bromine was the most useful. If the tissue were scraped first, and destroyed effectually by means of bromine, it often produced an amount of benefit that warranted our doing it, but it required great care, as it was a powerful escharotic.—Dr. BARNES, not having heard the paper, would limit his observations to one question of treatment referred to by the President. After the experience of quite a considerable number of operations, he had arrived at the conclusion that the most effective as well as the most safe mode of dealing with cancer of the cervix uteri was by the galvanic cautery. If the diseased mass were projected into the vagina in such a manner as to permit of being surrounded by a wire, it should be removed flush with the vaginal roof. There was rarely any serious bleeding, sometimes almost none; now and then, if a small artery spouted, the use of the porcelain cautery of the battery had effectually stopped it. In those cases in which the disorder did not form a projecting mass, the button galvanic cautery could be moved over the surface, destroying the necrosed portion. Comparatively healthy granulations commonly followed. The so-called cachexia disappeared for a time; there was almost always freedom from hæmorrhage for a time, and the general condition greatly improved. He had only known one casualty from the proceeding. A woman in St. Thomas's Hospital died a few days after operation from peritonitis. In all the other cases, reprieve and benefit were experienced. In one case, the subject had two pregnancies, and she was alive five years after operation although the disease returned.—Dr. WYNN WILLIAMS remarked that the cancerous matter might be deposited in any of the tissues of the uterus, as in other parts of the body; also that different forms of cancer began more frequently in one structure than in the other. Thus, the epithelial form commenced in the skin and mucous membranes, whereas the medullary commenced in the deeper seated parts; and with the uterus there might be cancerous deposit in any part of the uterine organs. He had seen in consultation three cases within the last twelve months, where he diagnosed cancer of the fundus. He did not think that anyone could well mistake the peculiar odour of a cancerous mass in its latter stages for the odour of a disintegrating fibroid. In cancer of the fundus, the greatest care should be taken in passing the sound, as a very eminent physician informed him, on one occasion, whilst examining the uterus, he was unfortunate enough to pass the sound through the cancerous tissues into the peritoneum, the patient dying in a few hours of peritonitis. There could be no doubt that the cancerous mass, wherever situated, should be removed when practicable, either by the *éraseur* or by the galvanic cautery, as mentioned by Dr. Barnes; and even if the whole of the mass be not removed, if the uterus be mobile, the surrounding tissues not infiltrated, we should endeavour to destroy the remaining portion, by injecting bromine into it, or applying it by means of cotton-wool. This he had done in several instances, where the neck of the uterus had been removed, and the actual cautery applied by other medical men, with the result apparently of removing the whole of that disease, for after a lapse of six or seven years the disease had not reappeared.—Dr. ROUTH said the Society might recollect his bringing the subject of uterine cancer forward several years ago, and subsequent experience only confirmed the opinions then expressed; indeed, one of those women, a case then believed to be hopeless, was, he had heard, still alive and in perfect health. He did not believe cancer of the fundus was quite so rare as had been stated; occasionally it was mistaken for fibroid; indeed it was quite impossible in many cases to make a diagnosis, because the bloody or fetid discharges were common to cancer and disorganising fibroids, or might occur independently of these, but if there was marked pain at night, which persisted for any length of time with hæmorrhage, it was safe to put down the case as one of cancer. Perhaps some very rare forms of neuralgic uterus with hæmorrhagia, might puzzle occasionally, but the previous history generally cleared up the case. When the cancer affected the cervix exclusively, and always in cases of papillary or epitheliomatous cancer, it was the right thing to remove it at once. He had done so in several cases, and many had had no recurrence. He usually employed the ordinary wire *éraseur* in preference

to the electric cautery, as it was much more easy of application, especially if the tumour was large or irregular, because the electric wire was so thin. Then, again, the electric wire often burnt a good way around the burning wire; and, if the cervix had to be taken away high up, there was fear of injuring the attachment of the vagina and uterus, and so getting into Douglas's space from the after sloughing, and producing death by peritonitis. He was not satisfied with leaving the case to heal at will after such excision. He waited four or five days, and then destroyed the surface again by means of bromine or the actual cautery, allowing the destruction to extend to part of the lining membrane of the uterus, if he had reason to fear it was diseased at all. And he often expedited the healing process, especially by a solution of gastric juice, which had a marked effect in bringing about cicatrization. This he had proved often, not only in cancerous sores but in others which turned out very obstinate and difficult of cure by other means. The marked difference between it and the perchloride of iron in healing power could be seen often, if we dressed a wound half with the iron and half with gastric juice; and he was glad to find that Dr. Barnes confirmed the healing power of this agent. A relapse would not justify cessation from further interference. A second operation often proved effective where the first had failed. Lastly, in cases of hopeless cancer, accompanied by fetor and loss of blood, and when a patient was dying a miserable death, he thought we should interfere. Destruction of the ulcerating surface often stopped both the general cachexia and gave great relief, and the patient gained temporary restoration of health. When the hæmorrhage proceeded from the cavity, he applied the persulphate solution of iron, or the perchloride, directly to the cavity, on lint; and, more recently, by means of an instrument similar to that devised by Simpson for passing caustic into the womb—though larger—he introduced into the cavity, either after dilatation by sea-tangle or without, if the opening were sufficiently patent, the dry solid perchloride, with the best results. Sometimes, the arrest of hæmorrhage was instantaneous, and seldom gave rise to any trouble; once only he had seen some metritis which supervened, and lasted three or four days. In any case, he thought it was perfectly unjustifiable to leave even hopeless cases of uterine cancer to die a miserable death, and be a pest to themselves and others, in our present state of knowledge, when so much temporary relief could be given.—Dr. AVELING stated, that after scooping or removing by any other means the cancerous structures, he had found nitric acid as efficacious and more easily applied than the actual cautery.—Dr. WILTSHIRE said he had used chronic acid with great benefit; it acted as a deodorant as well.—Dr. BLOXAM said, that all present would agree that it was of the utmost importance in those cases which were beyond the reach of operation, to mitigate the suffering caused to patient and friends by the extremely fetid discharges. He had heard bromine named, but not ioline or iodoform. The last was both a deodorant and an anodyne, and deserved more notice than it had yet received in this country. It could be applied in powder or wool, as a pessary with cocoa, butter, or in solution in glycerine.—Dr. EDIS remarked that the object of Dr. Liebmann's paper was to show that, in the majority of cases of cancer of the uterus, the disease commenced in the lining membrane of the cervix, and not primarily in the lower portion of the cervix itself. He (Dr. Edis) had long recognised the fact, and, in place of amputating the cervix by means of the *éraseur* or galvano-caustic, he had been in the habit of employing the actual cautery in the form of a pear-shaped bulb, to destroy the lining membrane and interior of the cervix, thus producing a conical cavity. He had represented the os uteri, which ultimately contracted, leaving merely a small aperture. In several instances, this had been attended by marked success, the patients living for many years after the date of operation without any apparent return of the disease. The chief points enabling us to arrive at a correct diagnosis as regards the fact of its being cancer were the almost undilatable condition of the cervix, the extreme tendency to bleed on the slightest touch, the fixidity of the cervical mucous membrane, and the rapidity with which the disease extended.—Dr. J. BRAXTON HICKS said, with regard to the deep burning of the galvanic wire mentioned by Dr. Routh, this was obviated by making the battery more powerful, and screwing up the wire more quickly. The galvanic wire had one great advantage over the ordinary *éraseur*; it cut quite clean and knife-like, and was adaptable to the more sessile growths; whereas the *éraseur* drew in and puckered up such forms, and brought away the softer portions, gliding off the harder, which it left behind. This he had seen frequently. With regard to the practice advocated by most of the speakers, viz., removing those parts which we could, and destroying the rest by cautery, caustics, or styptics, or other plan, he coincided; indeed, these he had advocated in papers elsewhere and at this Society. It afforded much benefit and comfort to the patient, removing the cachexia very effectually till the return of the disease. This he had shown in a paper in the *Guy's Hos-*

pital Reports some years since, and concluded that the so-called malignant cachexia was owing, not to the malignant diathesis, but to the absorption of the material from the malignant growth prior to the existence of sloughing, and though, after breaking up occurred, it was increased. Regarding the place of origin of malignant disease, he considered, as the result of observation, that it could spring from any tissue in the uterus and then spread to other tissues; that each fresh tissue affected would take on the action more according to its own nature than of that from which it was influenced; for instance, that epithelioma would not communicate epithelioma to fibrous or connective tissue; but, supposing epithelioma were first affected, and the malignant action extended to fibrous tissue, then rather that scirrhus was formed, and so in connective tissue we get the infiltrating kind, like that which occurs in the connective tissue in the breast. However, this opened up the question as to the nature of malignant disease at large, which was too wide a subject for the present time; but he would say, that he had seen on the confines of malignant disease of the cervix removed by amputation under the microscope, the mode of extension taking place in the nuclei of the fibre-cell, enlarging, then dividing, inside the old cell, bulging out its centre. In like manner, as he had pointed out in the *Guy's Hospital Reports*, and again in the *Pathological Transactions*, he had seen the nucleus in the wall of the blood-vessels enlarge, and then divide into two or three cells, bulging into the canal of the blood-vessel, giving it a bead-like appearance, but ultimately going on so far as to obstruct the current completely; and this would serve to explain why it was that sloughing readily occurred in some of these growths.—Dr. MURRAY agreed with the President as to the difficulty of diagnosis in cases of cancer of the fundus uteri and fibroid disease of the body of the uterus. He had lately seen a case where not until after death was it shown that true cancer of the fundus uteri existed, and death resulted from perforation of the uterine walls, with hæmorrhage into the peritoneal cavity. During life, none of the symptoms present more especially belonged to either cancer or fibroid disease.

Epithelioma of the Cervix Uteri, complicated with Pregnancy: Removal of diseased portions: subsequent Delivery of a Healthy Child: recurring Pregnancy.—Dr. CLEMENT GIBSON communicated, for Dr. CHARLES T. SAVORY, the particulars of this most interesting case. J. W., aged 35, married sixteen years, with eight children, had a sanguineous and, at times, watery discharge, offensive in character. A large cauliflower excrescence was detected and removed by the *éraseur* on October 27th, 1870. On January 12th, 1871, she was delivered of a female living child: both doing well. On June 25th, 1873, she was again taken in labour, and, after some little difficulty, turning was accomplished, and a dead child extracted, no undue hæmorrhage occurring. The patient succumbed thirteen days afterwards, apparently from sheer exhaustion, two years and nine months from the date of the first operation.—Dr. GORDON remembered the case well. The enlargement of the uterus was attributed to the disease supervening so immediately on parturition. Pregnancy being overlooked, the patient was, perhaps, spared the perils attending Cæsarean section. The case showed how much might be done to the uterus and its appendages during pregnancy, without abortion taking place.—The PRESIDENT asked whether the question of making incisions in the cervix to facilitate the expulsion of the child had been proposed in place of Cæsarean section.—Dr. MURRAY remarked that a practical point of great interest was that, even if pregnancy be diagnosed, there would be no harm in removing the mass.—Dr. J. BRAXTON HICKS remarked on the importance of having some rules for the management of cases of pregnancy in malignant disease of the cervix. He thought it, however, almost impossible to obtain any. Each case must be judged of by itself. However, in considering whether we should induce labour, or leave the case for Cæsarean section at full time, a primary question would arise, Can the woman live till full time? Again, in determining the question in regard to the induction of labour, Is the disease limited to the os and lower cervix, or does it extend to the lower part of the body of the uterus in such a way as to render delivery very difficult? If these be difficult, a third may arise, Can we leave the induction to the viability of the child, or must we procure abortion? So much depended on the amount and position of the disease, and the state of the patient, that Dr. Hicks feared it would be difficult to lay down definite rules. He instanced some of the cases which he had seen.—Dr. HEYWOOD SMITH thought it fortunate delivery did not happen soon after the operation, for he was sure that the puerperal state was a very great element of additional danger. He had a similar case some three years ago. Labour set in about the fifth month: delivery was effected by podalic version, and the child was born alive. Removal of the malignant disease of the cervix was effected by means of the *éraseur*, the tissue cut through being apparently healthy. The patient, however, died on the fifth day. The better practice would have been to

have postponed the operation until the puerperal state had been recovered from.—The PRESIDENT thought one of the most interesting points in the paper was, that the operation was performed without bringing on labour. It was generally supposed that no operation should be performed during pregnancy, even removing a tooth; but the case proved otherwise.

Mr. Spencer Wells, at the next meeting, will introduce the subject for the evening's discussion, The Relation of Puerperal Fever to Infectious Diseases and Pyæmia.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.

FRIDAY, MARCH 6TH, 1875.

JOHN ANDERSON, M.D., President, in the Chair.

On some Varieties of Pneumonia and Pulmonary Congestion. Dr. THOROWGOOD read a paper on this subject. He commenced by saying, that pneumonia may be looked at either as a disease attacking lung from without, as effect of cold, east wind, etc., or may be considered as a disease generated from within, the result of unhealthy condition of the blood. Any prevalent epidemic influence may modify either kind. Pneumonia is more prevalent during cold months. Grisolle's statistics show that, out of 296 cases, 20 occurred in January, 40 in February, 47 in March, 62 in April, 8 in June, 3 in July, 3 in August, 5 in September. Pneumonia prevails much in Iceland (Dr. Hjaltnin). In an epidemic (1873) strong healthy persons died in two or three days; this occurred often, and was the rule where no medical treatment was adopted. Dr. Hjaltnin saved many by bleeding, tartarated antimony, and calomel. Dr. Leared has observed that, though pneumonia is so common, phthisis is an almost unknown disease in Iceland. Dr. Thorowgood said, that very often pneumonia attacked the apex of the lung. In 224 of Grisolle's cases, the apex was affected in 101; the base in 133; the middle lobe in 30. Pneumonia is apt to attack the apex of the lung in persons in weak health, and exposed to insanitary conditions. Cases of complete recovery were adduced, proving that special pneumonia does not necessarily imply tubercle. In conclusion, the author drew attention to gravity of secondary pneumonia following pyæmia, and secondary to bronchitis; here, pneumonia was often central, and patchy or in blocks, not easily demonstrable by physical signs. Death seemed often to follow sudden suppression of expectoration from paralysis of the lung.

CORRESPONDENCE.

CONTAGIOUS DISEASES ACTS.

SIR,—A reply to Dr. Parkes upon any question of hygiene carries with it a sense of grave responsibility; and this is not a little increased when the question is one relating to the health of the army, and when (if we may judge from a letter in the JOURNAL of February 27th) his statistics, derived from one or two picked regiments, and for very limited periods, are to be accepted by the medical profession generally as conclusive of the beneficial operation of the Contagious Diseases Acts, notwithstanding the increase of secondary syphilis by one-twelfth, the increase of gonorrhœa, especially in the protected districts, and the increase of invaliding by about one-half in the whole army since the Acts were in force; the increase in the navy of gonorrhœa doubled at home and in the Mediterranean; the increase of primary syphilis doubled in the Mediterranean; the increase of constantly sick at home by one-eighth; the increase of invaliding abroad doubled in the home station; and, lastly, disease amongst the registered prostitutes increased by one-fifth, and deaths doubled since the Acts have been in force. The only form of disease in which there has not been an increase is the most indefinite class "venereal sores", which embraces both true syphilis followed by constitutional disease, and mere superficial sores of no consequence whatever. Of these, the true syphilitic element has increased (as is shown by the increase of secondary syphilis) ever since the Act of 1866 was in force; and the comparative reduction in the protected and the unprotected stations in the unimportant cases of disease remains to be determined by the information promised by the War Office.

In reply, however, to Dr. Parkes's letter in the JOURNAL of February 27th. He appears to think that I have not analysed his tables fairly, or as might have been expected from any one accustomed to figures. If I have been unfair, I sincerely regret it; but, as columns of figures, averages, and ratios, etc., convey little definite impression to most persons, especially if they become a subject of controversy, I will simply put them into a diagram, which will present them at one glance

to the eye in all their strength or weakness, and will probably convey a more definite or intelligible impression to the mind than mere figures.

Explanation of Diagram.—The figures at the top of the diagram represent the years, in Dr. Parkes's table, from 1860 to 1873 inclusive.* Those at the side indicate so many cases of disease per 1,000 men, and the figures in the body of the diagram are copied from his table, and show the exact ratio of cases of disease year by year. The lines show the direction of disease, whether increasing or lessening.

It would be impossible for any one examining the curve that represents either syphilis or gonorrhœa to fix upon the period of time in which a new agent came into operation, and showed itself of marked sanitary value by its effect upon the future progress of disease. It is perfectly certain that, if any one should make the attempt, and afterwards compare it with the real date of either the partial or complete operation of the Act (which I give below from Dr. Parkes's letter), he will find that he has selected a wrong year, and he will relinquish the attempt with the conviction that, so far as the course of disease amongst the Royal Engineers at Chatham is concerned, the Act, whether partially or fully enforced, has produced no perceptible effect in reducing it.

The diagram relating to primary syphilis shows clearly that, under the influence of causes which are still at work, this disease fell, though with considerable fluctuations, before the Act was passed, from 108 to 75 per 1,000, or a total of 33 per 1,000 in five years, equal to an average of 6.6 per annum. After the figures, the Act was partially in force for three years, and the disease, still fluctuating, fell upon the whole from 75 to 63 per 1,000, or a total of 12 in three years, equal to an average of 4 per annum instead of 6.6. After the figure 63, the Act was in full operation for five years, and the disease, still largely fluctuating, fell upon the whole from 63 to 44.6, or a total of 18.4 in five years, equal to an average of 3.7 per annum in five years under the full operation of the Act, instead of 6.6 per annum before the Act was passed. I am unable to see in this result any proof of the sanitary efficacy of the Act in reducing disease.

The diagram relating to gonorrhœa shows that this disease fell before the Act from 161 to 103 per 1,000 in five years, a total of 58, equal to an average of nearly 12 per annum. After the figure 103, the Act was partially in force until the figure 111, after which it was completely in force for the rest of the table; and the disease fell in these eight years of more or less complete operation of the Act from 103 to 69 per 1,000, or a total of 34 in eight years, equal to an average fall of 4.2 per annum since the Act, instead of nearly 12 per annum before the Act. In this result also I fail to see any proof of the sanitary efficacy of the Act; and it is to be remembered that this case of the Royal Engineers at Chatham has been specially selected by Dr. Parkes as a most conclusive proof of the beneficial operation of the Acts; for he says with reference to it, in his letter in the JOURNAL of January 23rd, "Does anything remain except the operation of the Acts to account

* 1874 is omitted from the diagram, because the new Army Regulations came into operation the middle of 1873, and have rendered all comparison since 1873 of no value.

for the decline of these diseases?" and again "I would now ask Dr. Nevins to look at all the army statistics, and say what more is wanted to prove to him that these Acts have conferred a most signal benefit on the army."—Yours faithfully,

J. BIRKBECK NEVINS, M.D. Lond.

3, Abercromby Square, Liverpool, March 12th, 1875.

P.S.—In my reply to Mr. Lawson in last Saturday's JOURNAL, there is a misprint, which I must ask you to correct. It appears in the JOURNAL as "renders the conclusions drawn in the *Parkes* papers". It ought to be "in the *Parl. Papers*", a contraction for Parliamentary Papers.

SIR,—Had Dr. Nevins taken the trouble to read my letter a little more carefully, he would have avoided the error he has committed by assuming that the 50th regiment was *seven* months at Aldershot, whereas in reality it was only *one*, viz., from 3rd July 4th August, on which date it embarked at Tilbury for Ireland. Consequently, both his argument and figures fall to the ground as worthless. This fact ought to make him a little more cautious in his remarks on a "slight misprint", when he makes such a glaring mistake himself, and actually makes it the basis of his whole argument in reply to my letter.

The conversion of Dr. Nevins must have been an easy process, when such facts as the one he mentions have had the effect of making him change his belief. Had he read carefully the remarks of the staff-surgeon of the *Excellent*, on the very table from which he takes his figures, he would have found the answer to his question. He says, "In respect to primary syphilis an improvement has taken place as compared with former years. There has been a considerable reduction in the number of cases, and it has been observed that, in those having the most unfavourable aspect, the disease was contracted at places not subject to the operation of the contagious Diseases Act." Again, in 1868-69, "the amount of primary disease was very moderate, considering the large complement, the almost unlimited leave, and the constant influx of men from foreign stations". Again, he writes, "considering that Portsmouth remains open to the influx of disease from all parts of the kingdom, the measure of success so far attained is as large as, if not larger, than might have been legitimately anticipated".

Surely Dr. Nevins does not imagine that the cases of the 50th regiment, and the crew of the *Excellent* are similar. Fluctuations in the number of admissions for disease frequently take place from various causes. In the instance given, the influx of diseased women from non-protected districts at certain seasons, and the unlimited leave granted, would to my mind be more than ample to account for the difference he points out. As a case in point, it is well known at Chatham, that, during the hop-picking season, the admissions are treble those of any other portion of the year. I have found it so myself when stationed there.

The opponents of the Acts complain of the small number of men, a picked regiment, and limited periods. I fear neither large nor small numbers will please them. Even the returns drawn up by Surgeon-General Balfour, and published in the Army Medical Report for 1872 (page 10), will not satisfy them. They do not go back far enough. Eight years is too limited a period to form a correct judgment as to the favourable influence of the Acts or otherwise. The fact is, the opponents of the Acts are driven to their wits' end for arguments to support their falling cause, and like drowning men they grasp at any straw that may float within their reach.

I am, Sir, yours faithfully,

N. FFOELLIOTT,

Dublin, 22nd March, 1875.

Surgeon-Major 50th regiment.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Thursday, March 18th.

Arrest of Miss Wood.—Mr. CROSS, in answer to Mr. Dillwyn, stated that his attention had been called to the arrest of Miss Wood as a lunatic, to her subsequent release, and her renewed confinement. The fact was, that the first certificate granted was defective. The medical men who drew up the certificate were referred to, and sent in the document again, still in a defective state. On this ground the unfortunate lady was released. A third certificate was issued by certain other medical men, who had examined the lady and found her insane, and she was therefore again arrested.

Artisans' Dwellings Bill.—On the order for going into committee on this Bill, Mr. CAWLEY criticised the measure at some length, contending that it failed to carry out the recital in the preamble with regard to

its expediency; that it ignored the powers now existing, and which in many respects were more efficient than the provisions of the Bill; and that it opened the door to the possibility of local governing bodies competing with the owners of house property. He moved, therefore, that the Bill be referred to a select committee.—The motion was seconded by Sir T. BAZLEY; and Mr. FAWCETT, who pronounced the Bill a halting, confused, costly, and complicated piece of legislation, also said that if the motion were pressed to a division he should vote for it. But in his opinion, reference to a select committee was not the best course to adopt. He suggested, therefore, that the Bill should be committed *pro forma*, and that the Home Secretary should, in the recess, consider which of the numerous amendments on the paper he would accept, and put the measure in a more intelligible form.—Sir S. WATERLOW, Mr. GREGORY, and Mr. GIBSON were anxious to go into committee at once, Mr. GIBSON declaring his belief that the Bill would turn out to be an effective and prudent measure, and expressing a desire to extend it to Ireland. Mr. Secretary CROSS answered the objections of Mr. Cawley and Mr. Fawcett, and added that, so far as the Government were concerned, they were determined that "rookeries" in large towns should be abolished, and the Bill was, in his judgment, the shortest and least expensive method of accomplishing that object.—Mr. CAWLEY then withdrew his motion, and the House proceeded in committee to consider the clauses.—On the second clause, limiting the Bill to sanitary areas of not less than 25,000 inhabitants, Mr. COWEN moved, as an amendment, the omission of the restricting words; but was defeated on a division by 99 to 36. A proposal of Mr. MUNTZ to include within the operation of the Bill sanitary districts of 10,000, led to much discussion, and was also negatived by 124 to 102.—Mr. CROSS moved an amendment, extending the Bill to urban sanitary districts in Ireland with a population of 25,000 and upwards.—He was opposed by Mr. RONAYNE and other Irish members, who wished to apply the measure to districts of 10,000 inhabitants; but the amendment was carried by 138 to 117, or a majority of 21.—Mr. FAWCETT proposed to extend the authority of the Metropolitan Board of Works over the City of London for the purposes of the Act, in place of allowing the City a separate jurisdiction in the Commission of Sewers.—Mr. CROSS dissented from the proposal, and said he believed that the City authorities would set an example to the other cities and towns of the kingdom, in showing how the bill could be worked.—Another division was taken, which resulted in the rejection of Mr. Fawcett's amendment by 222 to 84.—On the motion of Mr. CROSS, the Chairman reported progress.

Friday, March 19th.

Artisans' Dwellings Bill.—The House resumed the consideration, in committee, of the Artisans' Dwellings Bill at clause 3. Numerous amendments were discussed, but no division took place until Mr. FAWCETT moved to amend the 5th clause—"Requisites of improvement scheme of local authority"—by enacting that provision should be made for the accommodation not only of the working classes, but of all persons dispossessed of their homes under the Bill. This was negatived by 191 to 93. On reaching the 7th clause—"Duty of local authority to carry the scheme when confirmed into execution"—the Chairman was directed to report progress.

Monday, March 22nd.

Ship-Surgeons.—A return was ordered, on the motion of Captain BEDFORD PIM, "of the names, ages, and nationalities of persons who have served in the British merchant service during the last two years as surgeons, whose names do not appear in the *Medical Register*".

Medical Act Amendment Bill.—An Act to amend the Medical Act was presented and read the first time; to be read a second time upon Thursday, April 8th.

Public Health Act, 1872.—On the motion of Mr. O'LEARY, a return was ordered of the sums allowed out of the imperial Exchequer, for the years 1873 and 1874, to each rural sanitary authority in England, towards the salaries to medical officers and inspectors for performance of their sanitary duties under the Public Health Act (England), 1872; distinguishing, in the case of each authority, between the sum allowed towards the salary of inspector and that allowed towards the salary of the medical officer.

Medical Act Amendment (Foreign Universities) Bill.—A Bill "to amend 'The Medical Act, 1858', so far as relates to the registration of women who have taken the degree of doctor of medicine in a foreign university", was brought in and read the first time; to be read a second time upon Tuesday, 13th April.

Tuesday, March 23rd.

Infant Life Protection Act.—Mr. CHARLEY moved for a return from the local authorities, showing the number of houses in each of the

several districts specified in the first column of the same schedule, registered under the second section of the said Act: also setting out the number of infants registered in each year in each such house.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

CHAILEY RURAL SANITARY DISTRICT.—According to the report just issued by Mr. R. Gravely, Medical Officer of Health, it appears that, although no very decided sanitary action has been taken during the past year, and though the various subjects, which are deemed to be of an extensive and important character, have been, and are still, "under consideration", yet progress has been made in many essential details, and the medical officer himself has exercised an useful surveillance over his district, especially with regard to the adoption of means for preventing the spread of infectious diseases. The description given as to the condition of the dwelling-accommodation of the poorer classes shows how much remedial measures are required to ensure health and decency amongst this portion of the population, and how little has apparently as yet been done in this direction.

During the past year, this sanitary district is reported as having been free from any serious epidemic; but, in common with many other parts of the country, the amount of diphtheria has been exceptionally large. Owing to the obscurity which still hangs about this disease, both with regard to its origin and, in many respects, with regard to its method of spread, no greater service could well be done to the science of epidemiology than that medical officers of health should carefully note and record all the circumstances associated with the outbreaks which come under their notice.

THE DUTY OF MEDICAL OFFICERS OF HEALTH.

SIR,—As the JOURNAL is considered an authority on sanitary matters, can you inform me if it be any part of the duty of a medical officer of health to revise the certificates of death given by the medical practitioners in his district? Two cases have occurred within the last three months, in which our medical officer of health has reported to the Local Board that the certificates given by the medical attendants were incorrect, though he personally had not seen the cases, and could only form an opinion from hearsay. Is he justified in doing so? Further, is it etiquette for a medical officer of health to visit the patients of other practitioners without referring to them? I should like to know your opinion, as I acted very differently when I held the post, some few months since, of

MARCH 23RD, 1875. MEDICAL OFFICER OF HEALTH.

*** Certainly not, in either case.—ED.

THE Board of Guardians of the South Shields Union have increased the salary of Mr. George F. Henry, Medical Officer for the Westoe District, from £40 to £60 per annum.

MILITARY AND NAVAL MEDICAL SERVICES.

THE ARMY MEDICAL DEPARTMENT.

SIR,—Your remarks in last week's issue, on "Ministerial Explanations", regarding the existing vacancies in the Army Medical Department, would have been still more forcible had they included the consideration that it is not existing vacancies only that must be considered, but prospective (Mr. Hardy's word) vacancies. Does Mr. Hardy mean to say that there are likely to be but eight vacancies in the Army Medical Department during the next six months? Whether there will be more or not, there will be only eight men, at all events.—Yours truly,

VIGILANCE.

NAVAL MEDICAL APPOINTMENTS.

BU SHUTT, Staff-Surgeon William K., M.D., to the *Duke of Wellington*, additional, Copenhagen, Surgeon R. W., to the *Duke of Wellington*, for the Arctic Expedition, for temporary service at Haslar Hospital.
DYAN, Fleet-Surgeon J. E., to the *Warrior*.
MUIVER, Surgeon D., to the *Achilles*.
MELROSE, Surgeon J., to the *Arion*, as Supernumerary.
MOIR, Staff-Surgeon D., to the *Passante*.
MORTIMER, Fleet-Surgeon J. L., to the *Achilles*.
MOSS, Surgeon L., to the *Duke of Wellington*, for the Arctic Expedition.
O'CALLAGHAN, Surgeon J., to the *Cambridge*.
SWEETMAN, Surgeon J. C., to the *Warrior*.
SETHRELAND, Staff-Surgeon G. W., to the *Duncan*, additional, for temporary service at Yarmouth Hospital.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, March 18th, 1875.

Evans, Thomas, Pwllheli, North Wales.
Hallowes, Miller Coleman, Islington.
Houlbrook, Edward, Caius College, Cambridge.
Morris, George, Manchester.
Paxon, Herbert Elliott, Dorking.
Pettigrew, Augustus Joseph Welford, Hounslow.

The following gentlemen also on the same day passed their primary professional examination.

Brett, James, Birmingham.
Parker, Alfred Charles, Guy's Hospital.
Prichard, Arthur William, Bristol.
Smith, William Henry, St. Mary's Hospital.
Snell, Edmund George Carruthers, London.

MEDICAL VACANCIES.

The following vacancies are announced:—

BECKETT HOSPITAL AND DISPENSARY, Barnsley—House-Surgeon. Salary, £140 per annum, with furnished rooms, gas, and coals.
BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 1st.
BRADFIELD UNION—Medical Officer for the Fifth District. Salary, £53 1s. 8d., and fees. Applications on or before April 6th.—Resident Medical Officer. Applications to be made on or before April 2nd.
BRINTON, STREATHAM, AND HERNE HILL DISPENSARY—Resident House-Surgeon. Salary, £150 per annum, with furnished apartments, attendance, coals, and gas. Applications on or before April 5th.
DOVER UNION—Medical Officer for the St. Mary's District and the Workhouse. Salary, £180 per annum.
CALNE UNION—Medical Officer. Salary, £200 per annum.—Medical Officer for the Rural and Urban Sanitary District. Salary, £50 per annum. Applications on or before the 30th instant.
CENTRAL LONDON OPHTHALMIC HOSPITAL—Assistant Surgeon. Applications on or before April 3rd.
FARRINGTON GENERAL DISPENSARY AND LYING-IN CHARITY—Two Physicians. Applications on or before the 27th inst.
FETTERCAIRN, Parish of—Medical Officer and Public Vaccinator. Apply to Colonel M'Invo, Chairman of the Board, The Burn, Brechin, not later than the 27th instant.
HALIFAX UNION—Medical Officer for the Southwam District. Salary, £50.
HENSTED UNION—Medical Officer for the Second District.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST—Resident Clinical Assistant. Applications on or before April 5th.
LIVERPOOL ROYAL INFIRMARY—Resident Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications on or before April 10th.
MANSFIELD UNION—Medical Officer for the Fifth District. Salary, £32 10s.
MILFORD UNION, co. Donegal—Medical Officer for the Ramelton Dispensary. District. Salary, £100 per annum, and fees.
POOLE UNION—Medical Officer for No. 2 District. Salary, £60 per annum.
QUEEN ADELAIDE'S DISPENSARY, Bethnal Green—House-Surgeon. Salary, £100 per annum, with furnished apartments, coals, and light. Applications on or before April 1st.
ROYAL INFIRMARY FOR WOMEN AND CHILDREN, Waterloo Bridge Road—Physician.
ROYAL SOUTH LONDON DISPENSARY, St. George's Cross, Lambeth Road—Honorary District Surgeon. Applications on or before the 31st inst.
SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.
SOUTH SHIELDS UNION—Medical Officer for the Westoe District. Salary, £40 per annum.
SPLISBY UNION—Medical Officer for the Splisby East District. Salary, £40.
ST. JOHN'S WOOD AND PORTLAND TOWN PROVIDENT DISPENSARY—Surgeon. Applications on or before the 31st instant.
STRATTON UNION—Medical Officer for No. 3 District. Salary, £70 per annum.
TORBAY INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging.
WESTMINSTER HOSPITAL—House-Physician. Applications on or before April 5th.
WEST NORFOLK AND LYNN HOSPITAL—Resident Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications on or before the 30th instant.
WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL—House-Surgeon. Salary, £100 per annum, with board, washing, and furnished apartments. Applications on or before May 3rd.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication

DEATHS.

ADAMS.—Suddenly, on March 10th, at Bungay, Suffolk, Eliza, wife of Edward B. Adams, Surgeon, and third daughter of the late Thomas Fuller, Esq., of Aston, Berks.
*DAVIDSON, Samuel, M.D., at 142, King Street, Aberdeen, on March 22nd, aged 33.

No application having been made for the appointment of medical officer for No. 3 District of the Newmarket Union, the Guardians have resolved to add it to No. 1 District, and increase the salary of the medical officer of the latter from £40 to £85 per annum.

OPERATION DAYS AT THE HOSPITALS.

MONDAY Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAY Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAY St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAY St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAY Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAY St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

DR. JOSEPH SEATON'S letter, in support of the appeal in behalf of the family of the late Mr. Merryweather, shall appear next week.

COLOUR OF THE URINE IN AMYLOID DISEASE OF THE KIDNEY.

NIEMEYER, in his *Handbook*, asserts that his observations of the specific gravity and colour of the urine in amyloid degeneration of the kidney agree with the statement made by Traube, that it is of high density and dark colour.

I have collated the works of most of the English authors on renal diseases, and find that, with the exception of Beale, they all ascribe to the urine in waxy kidney characters the very reverse of those given by the above-mentioned German author, describing it as pale, watery, and of low specific gravity—1006-1015. Beale (*Kidney Diseases, Urinary Deposits*, etc.) however, states that the urine in this disease is "usually pale, often of considerable quantity, and sometimes of high density." And I have lately seen a case in which the urine remained for many weeks of a moderately high specific gravity (1020-1025, copious in quantity, and of the peculiar yellowish-brown colour described by Niemeyer.

I shall be glad if any of your readers will give an explanation of this marked difference in description, the discrepancy evidently not arising from observations having been made, on the one hand, in cases of simple waxy degeneration, and, on the other, in those complicated with intercurrent tubal nephritis, as the urine is invariably described as increased in amount. Yours, etc.,

Liverpool, March 23rd, 1875.

J. A. HARRIS, M.D.

JUSTITIA.—It would, we think, be invidious to publish "Justitia's" letter concerning the advertisement in question. The subject is better suited for discussion in a dental than in a medical paper.

AN HYDROPATHIC REPORT.

THE report of the Southport Hydropathic Hospital is, we are sorry to find, devoid of scientific value. The classification of the diseases is so vague, and the manner in which their character and progress are denoted is so vague, as to make the document worthless for any medical or scientific purpose. The so-called "medical report" is utterly destitute of data for any reasonable conclusions; 79 cases are classed together as "dyspepsia; duration—months and years"; 17 as "liver-complaints," duration, "years"; 13 as "brain-congestion"; 3 as "skin-diseases". Of course such a classification and method of reporting is unmeaning, and nothing can be made of the report. This is a pity, for discerning data from a public hydropathic establishment would be of interest, and possibly of value.

H. F. S.—The Brassica Eruca, or the Rocket Plant, is stated by Lobel to have been carefully cultivated in the gardens of monasteries and nunneries, to preserve the chastity of the inmates. But the ancients considered it a most powerful aphrodisiac, and consecrated it to Venus; hence Martial and Ovid:

"Et venerem revocans eruca morantem;"

And

"Nec minus erucas jubeo vitare salaces."

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

A CASE OF CONSCIENCE.

MR. HUGH REES of Llanberis has found himself obliged to resign a lucrative appointment held by him as surgeon to the Dinorwin Quarry, under circumstances of peculiar hardship. It appears that a trades union has been formed among the quarrymen, and the committee having demanded that the club should be placed under their control, as Mr. Rees's salary of £500 per annum was paid out of the funds, their demand was complied with. They immediately proceeded to introduce some important changes in the club rules, all of which were unfavourable to the surgeon in charge. These difficulties, however, might have been surmounted, but to these alterations were superadded the condition that a local bone-setter should visit the hospital once a week, or oftener if required, and should attend to the surgical treatment of any of Mr. Rees's patients who wished for his services; whilst the regular practitioner should attend to their general health. To this arrangement Mr. Rees naturally finds himself wholly unable to accede, and the committee are equally at a loss to understand why their surgeon should resign on a point which is, of course, in their eyes, utterly without importance. They are the more confirmed in this view, as applications for the post have already been made by some local practitioners who, less mindful of the dignity of their profession than Mr. Rees, are, he states, content to accept the indignity of acting in concert with an unqualified quack.

It would be much to be regretted the struggle for subsistence should lead members of an honourable calling thus to derogate from well-defined standards of professional conduct, and to lower the dignity of the profession, and depart from the principles of professional comity.

L. S. P.—1. The University of Paris has the "Faculté des Lettres" and "Faculté des Sciences" as departments. 2. The M.D. degree of Paris can only be obtained by a student after passing first as a Bachelor of Arts, subsequently five annual examinations at the close of each year's study in the several subjects of study, and four final examinations for the Doctorate. 3. An Englishman cannot practise, nor can any foreigner, without permission obtained through the ambassador, or passing an *ad eundem* examination.

A MEDICAL DISCOVERER.

WE have received Dr. Churchill's new big book on *Consumption, and the Principles of Stochiologial Medicine* (London: Longmans). We shall, however, simply decline to review it, contenting ourselves, and no doubt our readers, with the following quotation, p. 400:—"Just as seventeen years ago I claimed to have discovered a specific remedy for the tubercular diathesis, so now I deliberately assert that I have discovered a specific remedy for all inflammatory conditions of the respiratory organs . . ."; p. 406—"I have not stated, nor do I intend to state what these stochiologial inhalants are." It is not our business to discuss the alleged merits of secret remedies.

WILL the writer of a letter signed "M.D. Würzburg, M.R.C.S.," that appeared in our issue of last week, favour us with his address, which has been mislaid?

A LADY-DENTIST.

THE following interesting account of a lady-dentist at Berlin appears in *Women and Work*. "It appears that the lady in question (whose name I unfortunately forgot) was born in Schleswig, and married a dentist, who settled in Berlin. This man, after leading her for years a wretched life, died at last of intemperance, and left her without means of subsistence. Having often watched her husband at his profession, she fancied that she possessed sufficient nerve and dexterity to practise it too, and resolved to become a dentist herself. But here was the difficulty: the law forbade any one to practise dentistry without a certificate, which could be gained only by examination, and there was no examination for women. She was sadly puzzled; but, being informed (erroneously, as it proved) she should obtain a certificate by attending lectures and dissecting practice in America, after repeated applications to the professional authorities of Berlin, she was told by them that an American certificate would be accepted. She at once resolved to go to America; but, on arriving at Philadelphia, where her informant had given her to understand she could study without difficulty, on applying at the College of Dentistry in that place, she learned, to her surprise and disappointment, that no woman had ever applied before, and that no exception could be made in her favour. Her case, however, created much interest among the authorities, and was formally discussed there, and the result was, that the desired permission was granted her: one vote decided the question. She now set joyfully to work, attended all the required lectures with seventy young men, and worked with them in the laboratory. One of the professors kindly gave her private instructions, and she went through a private course of dissection. She succeeded in the examination, and began to practise in Philadelphia with such success that she was strongly recommended by her friends to remain there. She wished, however, to return to Berlin; and, accordingly, armed with her certificate, did return. She began the practice of dentistry in that city, confining her practice to women and children. She met at first with much opposition from her fellow-practitioners; but ultimately made head against it, especially after she had been introduced to the Crown Princess, and had been appointed dentist to Her Royal Highness's children. Engagements among the highest families in Berlin now flocked in upon her, and at the present moment she stands in the first rank of her profession. She is said to have great strength in her little hand, a flow of health and spirits, and works without weariness ten hours a day. In the evening, her saloon is the resort of the most intelligent and fashionable society in Berlin."

ENTOZOA IN GAME-BIRDS.

SIR.—Can any of your readers inform me whether it is customary to find entozoa in our smaller game-birds? Some days ago, while eating golden plover, I was surprised to find what appeared to me a small lumbricus in the trail: it seemed to move while watching it on the side of my plate. I am interested to know if others have made the same observation; if so, caution must be exercised in dealing with a *bonne bouche* in future.—I am, etc.,

J. G. CARRUTHERS.

* The plovers, in common with all other water birds, are largely infested with entozoa. The golden plover harbours a variety of different intestinal worms. The species referred to by our correspondent is probably *ascaris heteroura*. It may be swallowed by the human epicure with impunity.

A MEMBER.—Mr. F. Le Gros Clark, F.R.S., President of the College, who, delivered the Hunterian oration, was admitted a member of the College, February 15th, 1833. He became an Honorary Fellow, December 11th, 1843; a member of the Council in 1864; and of the Court of Examiners in 1870.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

MEDICAL TITLES AND DEGREES.

SIR,—Having read with some interest the discussion on this subject in your paper, I think you will not be averse to learn the opinion of one of the general public, on the assumption of the doctorate by medical practitioners. One who either claims or tacitly allows the title of Dr., seems to me to imply that he has had an University education, or at least has passed an examination beyond the ordinary professional ones. If this be not the case, his conduct is manifestly unfair to those who have graduated at an extra expenditure of time, work, and money. It is begging the question to say that an L.R.C.P. is a physician. He may practise as one, no doubt; but that does not prove him an university graduate. An M.D. may be a physician or not; this, as a non-professional, I will not presume to decide; but he certainly has the highest degree in his faculty, and a right to be called "Dr."

Another abuse you have not noticed is this: Universities have various reputations, so we find men writing M.D., L.R.C.P. Lond., etc. On turning to the *Medical Directory*, we find that the degree was taken at Erlangen, Giessen, or Edinburgh or Glasgow, which may be good degrees or not; but evidently the holders wish the public to think they have passed the stringent course required by the Metropolitan University. A case occurred within my knowledge where a gentleman took the Erlangen degree on his wedding trip—the regulations as to residence cannot have been very serious.

A word as to the assumption of the title of Dr. by M.R.C.S. This looks like a shabby attempt to seem on a par with those who have passed the extra examination usually and paid the fees always required for the M.D. If an M.B. is Dr., we may ask, as the cheap shops do, "Why go further?" In other professions, men are more modest. When an L.L.B. I did not assume the title of Dr., or expect to be so called; nor have I ever heard of any one else who did. The same applies to Bachelors of Divinity. And, indeed, it seems anomalous for young fellows of, say, three or four and twenty, to come out apparently as Drs., when in Law and Divinity a man does not ordinarily obtain the doctorate until, in some cases, ten years after matriculation. I pass by the fact that every medical man is colloquially a doctor; what I complain of, is his styling himself so. Some medical papers, too, seem to affix the title to all their subscribers in their printed addresses, no matter what their qualifications, and I cannot help thinking this tends to foster the delusion.—I am, dear Sir, yours respectfully,

M.A., LL.D. (both Lond.)

SIR,—In the correspondence in the JOURNAL under the heading of "Medical Degrees and Titles", the original question of what medical qualification confers the right to the title of doctor has been lately mixed up with two others, which ought to be kept quite distinct, viz., the relative merits of the various examinations, and the supposed hardship, that practitioners of some years' standing have not greater facilities afforded them for obtaining the degree of M.D.

Now, whilst passing by the two latter questions as having no bearing whatever upon the subject under discussion, I will, with your permission, address a few remarks to the question of who has a right to the title of doctor. And first, I think I may take it for granted, that in order to have a right to the title a man must be a doctor, and then, that if a doctor, he must be doctor of something. Secondly, to be a doctor he must have had the degree of doctor conferred upon him; but, in this country at least, degrees can be conferred by universities only. Now if the above statements are correct, it is not simply childish for L.R.C.P.s to lay claim to the coveted prefix; I myself know many L.R.C.P.s, both of London and Edinburgh, but although many of them have "Dr." emblazoned upon their houses, or printed upon their cards, I do not know one who has the hardihood to assert in conversation that he has a right to the title.

But, sir, it seems to me that this question of medical titles has a greater importance attached to it than that derived from the mere question of right to a particular title; for if those practitioners who have no legal right to the title lead the public to suppose that they really are doctors, by themselves assuming that title, are they not practising under false pretences, and can such a proceeding be looked upon as either professional or honorable? I really think that the profession should take action in this matter as the evil is rapidly increasing; for while a few years since it was the exception for an L.R.C.P. to call himself Dr., the exception is now the other way. I think, indeed, that it is a subject well worthy the attention of the British Medical Association, or of the heads of the profession.

For myself, I cannot understand how any gentleman of good feeling can assume a title to which he cannot lay claim. In what respect, except that of degree, does he differ from the unqualified quack who also represents himself to the public as something that he is not? Ours is, I regret to say, the only profession in which such a thing occurs. Did a clergyman ever call himself doctor without possessing the degree of D.D. or a barrister without that of LL.D.? It has been argued that the fact that the public generally call a medical man "Dr.", is a justification for the assumption of the title, but if that be so, then M.R.C.S. and L.S.A. ought also to be called "Dr." The real question is, not what the public call a man, but whether he calls himself by a title he has no right to. This I consider to be derogatory to our profession, and ought, therefore, to be marked with united disapprobation; and I think that this object might be effectually accomplished, if either a general or total organisation were formed of medical men who would agree to refuse to meet any practitioner who used a title wrongfully.

I am, Sir, yours faithfully, M.D. HACKNEY.

P.S.—Of course M.R.C.P.s or M.B.s calling themselves "Dr.", occupy precisely the same position as L.R.C.P.s, so far as their right to that title is concerned. I would myself, however, always address an M.B. as doctor, in the same way that naval commanders get the courtesy title of captains, but they do not on that account call themselves captains.

SIR,—I have read with much pleasure the interesting correspondence carried on in the JOURNAL under the heading, "Medical Titles, etc.," but I cannot perceive that any appreciable progress has been, as yet, made towards a solution of the crucial points in dispute, which, I take it, comprehends the following questions:—1. Have L.R.C.P.s the right to call themselves "doctors"? 2. If not, then what means have they of imparting to the public the knowledge of their possession of that title? As to the first point, opinion seems to be very much divided amongst your correspondents; but I believe, that if each individual member of our Association were asked to record his vote on the point, the sense of right and justice

would result in a majority being of opinion that the legal and moral right to the prefix "Dr." belonged to the "Doctor of Medicine".

With regard to the second point, I presume the great desire amongst L.R.C.P.s is that the public should be aware of the superiority of their professional status to that of those miserable mortals who have the misfortune to be dubbed simply M.R.C.S. and L.S.A. I grant them that they have an undoubted right to that superior position; but, I scarcely think it just to accomplish that object by calling themselves "doctors", and thus arbitrarily placing themselves on an equality (at least in the public mind), with that most unfairly treated individual, the M.D. Assuming the title of "doctor" to be legally denied them, are there still no means of soothing their sorrows, or of satisfying their rightful ambition? I think there are. I take it, that the right of an L.R.C.P. to the title of "physician" has not been disputed; and if that be really the case, let them take courage, for have we not, then, a solution of the difficulty?

Why should not all L.R.C.P.s discard the uncertain for the certain, and at once set about having door-plates and cards engraved with the magic prefix, "physician"? Thus, "Physician Jones", or "Mr. Physician Jones", on one's door-plate or card, would be conclusive and imposing evidence to the public mind (which dearly likes anything new), of his superior status to that of his poor relation, the M.R.C.S. and L.S.A. next door, whom we might term "Surgeon Brown", and might even jeopardise, by its novelty, the position of the veritable Dr., the M.D. himself.

That the above suggestion may lead to a satisfactory solution of the difficulty hitherto experienced by the unfortunate L.R.C.P. in setting himself right with the public, without encroaching on the rights of the M.D. to the sole assumption of the title "Dr.", is the fervent wish of,—Sir, yours most truly,

A WELSH ASSOCIATE.

WE are indebted to correspondents for the following periodicals, containing news reports, and other matters of medical interest:—The Cork Constitution; The Glasgow Herald; Saunders' News Letter; The Argylshire Herald; The Birmingham Morning News; The Birmingham Daily Post; The Hampshire Telegraph; The Newton Directory; The Sheffield Daily Telegraph; The Berkshire Chronicle; The Hackney Express; The Bath Argus; The Portsmouth Times; The Liverpool Mercury; The Alcester Chronicle; The Hereford Times; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. Burdon Sanderson, London; Mr. Fairlie Clarke, London; Dr. R. S. Williamson, Punjab; Dr. Lutaud, London; M. Gamet, Paris; Dr. De Villiers, London; Dr. R. J. Lee, London; Dr. A. L. Galabin, London; Dr. W. H. Corfield, London; Mr. T. A. Wykes, Leicester; Mr. Joseph Taylor, Buxton; Dr. W. D. Stone, London; Dr. John Haddon, Eccles; Dr. Evans, Reading; Dr. F. H. Haynes, Leamington; Dr. J. Marion Sims, New York; Dr. Gaillard, Louisville; Mr. A. C. De Renzy, Punjab; Mr. E. Cooper, Norwich; Dr. J. LECTURES

ON

THE OCCURRENCE OF ORGANIC FORMS
IN CONNECTION WITH CONTAGIOUS
AND INFECTIVE DISEASES.*Delivered at Owens College, Manchester.*

BY

J. BURDON SANDERSON, M.D., V.P.R.S.,

Jodrell Professor of Physiology in University College, etc.

LECTURE III.—(Continued.)

THERE are two contagious diseases besides small-pox, in respect of which there is reason to suppose that specific organic forms exist either in the blood or in the affected tissues: namely, relapsing fever and splenic fever. I propose to take splenic fever first.*

Splenic fever is a malignant highly contagious disease of cattle, distinguished by the extreme rapidity of its course and fatal termination. It is interesting to us on account of the fact that it is characterised by the existence in the blood of organisms which, from the investigations of trustworthy observers, seem, though like common bacteria in form, to have such marked peculiarities of their own, that they may be regarded as specific. These bodies were discovered in 1855, or perhaps earlier; but their significance is still matter of dispute, there being great difference of opinion (even among those who admit that they are characteristic of the disease) as to the part they play in the morbid process.

The disease may be communicated by any means which involves the transference of a portion of the blood of a diseased animal to the living tissue of an animal previously healthy. It is not known that it can be propagated by any other way; for animals kept in the closest proximity to diseased ones, and placed under the most favourable conditions for infection through the air, are not infected.

The most striking feature of the disease is its extremely rapid progress and its short duration: in the so-called apoplectic cases, a few hours; in the more ordinary ones, a day or two. A sketch may be given in a few words of the disease as it presents itself in acute cases in cattle. An animal, which perhaps for the previous day has declined food and shown signs of general disturbance, begins to shudder and to have twitches of the muscles of the back, and soon afterwards becomes weak and listless. In the meantime, the respiration becomes frequent and often difficult, and the temperature rises to three or four degrees above the normal; but soon convulsions, affecting chiefly the muscles of the back and loins, usher in the fatal collapse, of which the progress is marked by complete loss of power of moving the trunk or extremities, diminution of temperature, mucous and sanguinolent alvine evacuations, similar discharges from the mouth and nares, and death. In the horse, the disease presents similar characters, but is much less acute. The local affection is more frequently recognised during life, so that the case is often recorded as one of "acute splenic tumour".

Of the phenomena revealed by dissection, those which relate to the blood, to the circulatory and lymphatic systems, and to the spleen, are by far the most important. In the blood, the colourless corpuscles are increased, especially in the horse. In the mucous membranes, general infiltration is one of the most marked results of the disease. In cattle it is excessive, and affects the whole course of the intestine, the cavity of which is found to be full of sanguinolent transudation. In the horse it localises itself in the stomach and duodenum, and presents itself in the form of circumscribed inflammatory tumours or thickenings of the mucous membrane. As, in these tumours, the inflamed tissue dies in the middle and sloughs out, leaving an ulcer, they are called carbuncles. The ulcers are called "typhous ulcers", and the whole disease in the horse is often designated "typhus".

The discovery that in the blood of animals affected with splenic fever rod-like bodies are found in the liquor sanguinis was first, I believe, made by Pollender, who, in the year 1855, described them as "fine, apparently solid, straight unbranched objects". He stated that they possessed no proper motion, differing in this respect from ordinary

bacteria, leaving the question of their nature, as well as that of their relation to the contagion of the disease, open. A year or two after the publication of Pollender's paper, Brauell published the first of his very extensive series of researches on the contagion of splenic fever, in which he not only confirmed Pollender's discovery, but, by experiments in which he communicated the disease to animals under a great variety of conditions, acquired for pathologists the greater part of the accurate knowledge they now possess on the subject. He contented himself, however, with demonstrating that the organisms found in the blood in splenic fever were characteristic of the disease, without maintaining that they were, or that they were not, the causes of its virulence; and, indeed, was disposed to attribute more importance to them as diagnostics than as agents in the morbid process.

Three years later, the bodies in question were rediscovered by Delafond and Davaine, who, in claiming a priority which did not belong to them, no doubt did so in ignorance of the good work that had already been done in Germany. The existence of the rods as a characteristic of the circulating blood in animals affected with splenic fever, is a fact now admitted by all pathologists who are conversant with the disease. It is, however, remarkable (and at first sight difficult to understand) that many observers have expressed doubts as to their being organised living beings. Thus, Leisering at first took them for fragments of fibrin or for bits of tissue; others thought that they were blood-crystals. The statement made by Professor Bruckmüller of Vienna, and repeated by others, that Virchow at one time regarded the bacteria of splenic fever as blood-crystals, appears to be an erroneous one, founded on a misquotation of an oral communication.

The rods have been most carefully studied by Bollinger in his recent *Researches in Comparative Pathology*. Each rod is about as long as the width of a blood-corpuscle. Along with the rods spheroids can always be found, which are no doubt forms of the same organism—parts of the same continuous development. As regards their structure, examination with high powers shows that each rod is made up of spheroids, each spheroid consisting, like an ordinary micrococcus, of a central darker part with a more transparent envelope. The most remarkable fact relating to them is, that they disintegrate rapidly from the moment that the blood becomes putrescent. As they disappear, the actively moving rods and spheroids, which indicate the commencement of the septic process, take their place, but there is no continuity of development between the two kinds of organisms.

The principal source of doubt as regards the part played by the rods in the contagious process of splenic fever has been the observation first made by Brauell, that, in the early stage of the disease, no rods are found in the blood; and that nevertheless such blood possesses the contagious property. This question has been lately investigated very fully by Professor Bollinger, on the basis of experiments made expressly for the purpose. From the results of these experiments, it seems certain, (1) that blood without rods may yet be contagious; (2) that animals infected by it contain the rods in their blood in as great numbers as others. Are the rods, therefore, intimately associated with the contagious material—the contagium? or is their appearance a merely collateral phenomenon—a symptom of the disease?

It has been sought to answer this question in two ways: on the one hand, by separating the rods from the liquid, and determining their pathological properties by experiment; and on the other, by testing the activity of the liquid after the rods have been removed from it by some process of filtration. The first of these methods—that employed, or rather attempted, by Davaine and the French experimenters—has led to no result; and it is difficult to see how it could yield any; first, because complete separation of such organisms from the medium in which they are contained is impossible; and secondly, because, in the very act of filtration, the organisms themselves would probably undergo such changes as would entirely alter their properties. If, as is probable, the activity of the rods is dependent on their vital functions, there is no reason to anticipate that they would continue to manifest that activity when "out of their element"; still less that it would show itself in any descendants or progeny obtained from them by the method of cultivation. The other method has been used by Klebs and Tiegel. These observers have found that, just as it is possible to separate the bacteria contained in ordinary septic products from the liquid in which they are suspended by filtering them under pressure through a stratum of porous porcelain, the same method can also be successfully applied to blood containing the rods of splenic fever. The result of the experiments, which, it must be admitted, were not so frequently repeated as could have been wished, was, that the filtrate of blood (or rather the liquid of the spleen of a diseased animal), of the virulence of which experimental proof had previously been obtained, was found to be incapable of communicating the disease. Clearly, there is no proof in this fact that the contagium of splenic fever is exclusively contained in the

* The facts stated in this part of the lecture will be found in greater detail in the introductory paper already referred to contained in the Reports of the Medical Officer of the Privy Council on Scientific Investigations (New Series, No. 111).

rods: but there is proof in it that the agent is, as we believe all other contagia are, a body which is incapable of solution or diffusion, and which attaches itself to concrete particles.

An additional and to my mind more satisfactory proof of this lies in the remarkable observation made by Brauell, that, when pregnant animals are affected with splenic fever, the blood of the embryo is not contagious. Brauell found in repeated trials that, in such animals, blood from the fetal circulation could be inoculated without result. Here the placental apparatus serves not merely as a filter, but as a diffusion-cell, keeping back not merely solid particles, but everything which is not capable of passing through animal membranes. This fact—of the immunity of the fetus—must be taken in connection with the incommunicability of the disease excepting by actual transference of blood.

The contagium of splenic fever is wonderfully persistent. With reference to this point, there is an apparent antagonism of facts, which, however, on examination, turns out to be a perfect agreement. Brauell found that blood, after removal from the body, loses its activity in a few days. On the other hand, we are certain that the contagium must have a state of existence in which it is in the highest degree permanent and indestructible. Thus Bollinger gives an account of what may be called a stable-enzootic of splenic fever, in which ten cases occurred in one stable during a period of three years, no other cases occurring in the neighbourhood. The contagium must have remained latent during the whole period.

What does this mean? Here is a disease only transmissible by inoculation, and of very short duration. Why does it not perish out of existence? Clearly it would do so, had it not some as yet unknown means of perpetuating itself. How it does so, it would be too bold to conjecture. The rods can hardly be supposed to be the means of perpetuation; for, like the contagious property which they perhaps represent, they are very fugitive, and, in particular, like it and along with it, they disappear at the moment that putrefaction commences. It is, therefore, not possible to refer to them as contrivances suited for the storage of contagium, or for its conveyance to a distance, for either of which purposes they are obviously unfit. This very consideration, however, can, I think, be made to appear rather as an aid to our understanding of the relation between organisation, or rather living organic forms, and contagion, than as a difficulty or objection. For, if we turn from the specific form to what we know about the development and life-history of common bacteria, and, indeed, of the beings belonging to the same group in general, we find the same thing. Just as in the case of the specific contagium, we are compelled to recognise two states of existence, one enduring and latent, the other active, but fugitive: so among these organisms we find one condition in which the growth and multiplication of individuals is very active, but individual life is extremely short; another in which the vital activities of the organism are stored up for the future, the individual being for this very end endowed with the power of resisting external disintegrating agencies, and thereby of enduring for an indefinite period. Thus, without any effort, we find, in all probability, in the life-history and development of the organisms, the counterparts of all the phases of the process of contagion.

During the last few years, the pathology of splenic fever has acquired an even wider interest than it had before, from the publication of a series of cases of a rapidly fatal disease affecting the human subject which presents the characters of splenic fever, and turns out, on investigation, to be identical with it. The first of these cases was published by Professor Buhl at Munich in 1868. It was that of a man aged 32, who died after a short illness, of which collapse and vomiting were the chief symptoms. After death, the stomach and duodenum were found to be the seat of circumscribed foci of submucous infiltration, presenting characters similar to the so-called "carbuncles" of the intestine seen in the horse. The rods of splenic fever presented themselves in the blood, and the other lesions corresponding to those of the disease in question were found.

The affection was termed by Buhl "*Mycosis intestinalis*." Shortly afterwards, two other cases were recorded by Prof. or Waldeyer, now of Strasburg. In one of them, that of a slaughterer, whose occupation pointed to the sources of infection, the nature of the disease was suspected during life. After death, the suspicion was confirmed by the complete correspondence of the lesions with those of splenic fever in the horse. As in Buhl's case, the microscopical investigation showed that masses of *zooglia* existed in the affected tissues, and that rod-like microphytes were to be found in the circulating blood, particularly in that of the portal vein. Other rapidly fatal cases have since been removed, all of which exhibited pathological appearances of the same kind, the most constant being the enlargement of the spleen and the circumscribed hemorrhagic infiltrations of the intestines, resulting in

more or less extensive sloughing of the mucous membrane, and associated with serous exudations, infiltration of the subserous tissue, and hyperæmic enlargement of the lymphatic glands in relation with the infiltrated parts.

Whatever doubt remained as to the identity of *mycosis intestinalis* with splenic fever, was removed by the appearance of a communication by Dr. Munch of Moscow, who was able to state, from the results of his own dissections in the "Workman's Hospital" at that place, that in all the cases in which he had occasion to examine the bodies of men who had died of disease contracted by infection from animals, the intestinal lesions and the condition of the other internal viscera corresponded closely with those described by Buhl and Waldeyer. In these, as in many other cases recorded by the best observers, the primary pustule (*pustula maligna*) at the seat of inoculation, often supposed to be the one pathognomonic lesion of splenic fever in man, was by no means a constant feature. Out of twenty-eight cases recorded by Munch (1867-71), seventeen exhibited a primary pustule, which in all but two was carbunculous; but, in the other eleven cases, there was nothing whatever to be found on the skin.

As regards the morphological relations of the organisms found in *mycosis intestinalis* with those of splenic fever, further investigation is required. So far as the former have been described, they agree completely with the others, as may be readily seen by comparing the drawings of Wagner, taken from a case of *mycosis*, with Cohn's or Bollinger's representations of the rods of splenic fever.

The identity of the two forms being admitted, Buhl's and Waldeyer's anatomical investigations afford a key, which was before entirely wanting, to the understanding of the so-called "localisations" of splenic fever in cattle. This key consists in the demonstration that the formation of foci of infiltration, of which we read so constantly and repeatedly in the descriptions of the veterinary pathologists, is a process of which it is the characteristic that the tissues of the infiltrated part became infested by myriads of microphytes of a particular kind, so that the presence of these bodies is as much a part of the process as the emigration of the colourless corpuscles from the blood-vessels is a part of ordinary supuration. Further than this it is not possible to go, until the initial stages have been investigated in the lower animals.

I now pass to a disease which in two or three respects resembles splenic fever, while it differs from it in a great many more. As regards its mode of diffusion, there is this striking resemblance, that, although relapsing fever does not require inoculation in order to communicate itself from the sick to the healthy, the area within which its contagium can act is very limited. If a patient be introduced into a ward, the patient in the next bed may be attacked, but the disease does not spread. In the recent epidemic at Breslau, to which I am about to refer, there were many instances in which the disease found its way into rooms inhabited by several families, and it was then observed that the members of one family (in other words, those who lay on the same heap of straw) were attacked one after another, while the other occupants of the room remained exempt.

Another striking point of resemblance lies in this, that they are both pre-eminently blood-diseases. In the case of splenic fever, we have direct evidence of this in the fact that the disease is conveyed by transfusion of blood. Whether this is also true as regards relapsing fever has, of course, not been ascertained; but we have, as indications of the blood-affection, first, the fact that the spleen, of which the function is intimately connected with the blood, is enlarged in a similar way in both diseases; and, secondly, the fact which at the present moment specially interests us—the recent discovery that, in the blood of persons suffering from relapsing fever, organisms exist, which, from their remarkable form, are called *spirilla*.

During the prevalence of relapsing fever in Berlin in 1872, Dr. Obermeier, who had, in the previous epidemic of 1868, been engaged in microscopical investigation of the blood, announced the discovery of the *spirilla* in a communication made to the Berlin Medical Society. This communication was based on twelve cases, in all of which the organisms were observed. On March 26th, Dr. Obermeier published a second series of observations: twenty new cases had been investigated, in nine of which the blood had been examined daily. The results of these examinations showed, that the presence of the organisms in the blood was associated with the morbid process so closely, that as soon as the pyrexia disappeared they disappeared with it, reappearing when the patient again febrile in the relapse.

Soon after the death of Dr. Obermeier, a third series of observations was communicated by Dr. Engel to the *Berlin Medical Weekly Journal*, founded on the examination of the blood in eighteen cases in the Charité Hospital at Berlin, under the care of Professor Frerichs. They confirmed in every particular the statements of Obermeier, deriving additional value from the exact observations they contained as to

the time which intervenes between the onset of pyrexia and the first appearance of the organisms.

During the same year, the epidemic prevalence of relapsing fever at Breslau afforded additional opportunities for investigating the subject. The first results of these inquiries were communicated by Dr. Weigert to the Silesian Scientific Society on September 12th, 1873. The clinical relations of the subject have since been worked out by Dr. M. Litten in a report on the epidemic founded on observations in the General Hospital in Breslau.

In this report, Dr. Litten has given by far the most complete account of the spirilla that has yet been published. He confirms the statement of Obermeier that they are found only in the blood of persons affected with the disease. In more than one hundred cases they were never missed. They occurred only during the paroxysms, and invariably disappeared before the fall of temperature—never remaining during the period of apyrexia. Their number, however, varied considerably; they were sometimes so numerous as to crowd every field, at others they were difficult to find. Dr. Litten describes their motions as partly consisting in undulations which progress along the course of each fibril, and partly in oscillatory movements, *i.e.* alternate flexions and extensions, springing from some point in the course of the fibril.

Dr. Litten made some very interesting observations on the relation of these remarkable bodies to temperature. He observed that on raising the temperature of the stage of the microscope gradually to 60 deg. C., no effect was produced. As soon as this point was passed, the movements became languid. By the time that 65 deg. was reached, they had entirely ceased. No effect was observed on cooling the preparation to the temperature of freezing. When it was kept for some time on ice, the movements finally disappeared.

Here I stop. I have brought before you, to the best of my ability, the leading facts relating to the only four cases known to me in which the connection between organic forms and specific diseases has, as yet, been satisfactorily made out: those of cow-pox, sheep-pox, splenic fever, and relapsing fever. These four diseases, although they are so different, are associated by the fact that each of them presents very well marked nosological specificity—in other words, they are all of them characteristically contagious diseases. Small-pox we must not yet include, excepting on the ground of identity with cow-pox; but we may hope that the researches of Dr. Weigert, as soon as they appear, will afford us material for conclusions on this subject. In the meantime, let us carefully guard against undue precipitation, in the process of combining the few facts we are already in possession of into a system. The desire to discover the practical bearing of his results on the all important questions of prevention and treatment is a constant and ever recurring temptation to the scientific pathologist, seducing him from his path of patient and silent investigation into speculations about the origin and nature of disease which, even though they may sometimes lead to useful practical applications, have no permanent value.*

* Since this lecture was delivered, the first part of Dr. Weigert's Researches have been published at Breslau, with the title *Anatomische Beiträge zur Lehre von den Pocken*.

TREATMENT OF CLUB-FOOT.

I WISH to call attention to a particular passage in Dr. George Buckland's paper on Club-foot, which deals with the "Non-cutting treatment." He says "A muscle of its (tibialis anticus) length, even when very rigid, can be stretched to a considerable degree: *if there are any cases of club-foot cured 'without cutting tendons'*, as some surgeons would have us believe, they must be trifling examples of the deformity, and the defect must depend wholly upon the long muscles of the leg, which is very rarely the case."

Mr. Barwell's method, in its entirety (shampooing, etc., mentioned by Dr. Buchanan, as well as mechanical means) has been adopted here during the past six months, by the advice of Mr. Wright, our senior surgeon, by whose kind permission and assistance, together with that of the staff generally, I have been enabled to collect a series of cases, the results of which I hope to publish at some future time. So far the treatment has thoroughly borne out all that has been stated by Mr. Barwell when advising its use. That there are cases of talipes, and the majority of such, which can be treated successfully by this method, our limited experience leaves no doubt. Dr. Buchanan lays great stress upon the early adoption of means for the cure of these deformities, and Mr. Barwell equally so; the success or non-success of treatment, in either case, depending mainly upon this; but, in the latter, it is also influenced by the amount of patience and perseverance possessed by the surgeon in whose hands the case may be.

L. W. MARSHALL, M.D.,
Resident Surgeon to the General Hospital, Nottingham.

THE CROONIAN LECTURES ON ADDISON'S DISEASE.

Delivered at the Royal College of Physicians, London.

By E. HEADLAM GREENHOW, M.D., F.R.C.P., F.R.S.,
Physician to and Lecturer on Medicine at the Middlesex Hospital.

LECTURE III.

THE lesion in the suprarenal capsules in Addison's disease is produced, as I have shown, by an inflammatory exudation of low type with which these organs become infiltrated. This exudation becomes converted into a firm fibrous material, which first encroaches upon and destroys the normal tissue of the capsules, and subsequently itself, together with the destroyed elements of the organs, undergoes degeneration into purulent, cheesy, or cretaceous material. At first it would, not unnaturally, be supposed that this complete destruction of the normal structure of the capsules must be the immediate cause of the symptoms in Addison's disease; or, in other words, that these symptoms must result from the abolition of the proper function of those organs. This was evidently the opinion entertained by Addison when he published his book; for he expressed his belief that the urgency of the symptoms was determined by the actual amount or degree of morbid change going on in the capsules, and that, whilst universal disease of both capsules would probably be found to be uniformly fatal, cases in which the morbid change was limited to one capsule only might be found to be attended with proportionately slighter results. Since Addison's time, however, it has become generally recognised, by all those acquainted with the subject, that the symptoms associated with the suprarenal lesion cannot proceed from mere destruction of the tissues of the organs, and consequent abolition of their function. Many physiological experiments have been made upon animals, by Dr. Brown-Sequard, Dr. George Harley and others, with the view of deciding this point; but, looking to the differences in their results, and to the doubt how far these may have been due to accessory differences in the operative processes, I am disposed to attach much more weight to the clinical and pathological facts which seem to me to determine the question.

In my last lecture I showed, on the one hand, that when the normal structure of the suprarenal capsules is altogether supplanted by cancer, or has undergone complete fatty degeneration, none of the peculiar symptoms of Addison's disease are produced, notwithstanding the total destruction of the organs for all functional purposes; and, on the other hand, it is quite certain that, in many cases of Addison's disease, the conversion of the suprarenal capsules into a mass of fibroid tissue, and even the degeneration of this latter into cheesy material, must have been almost, if not altogether, complete before the development of any of the characteristic symptoms of the disease. In the case of the little girl, E. W., for example, the profound alteration in the capsules, more especially in the right one, which consisted chiefly of cheesy masses with some gritty matter bound together by translucent tissue, could not possibly have taken place to any extent during the brief period of her illness; and, in other cases in which the illness has been equally short, the capsules have been found in a still more advanced state of degeneration. Messrs. Rossignol and Little report a case of a servant girl, aged 15, whose illness had been noticed only four weeks before her death, and yet both suprarenal capsules were in a great part made up of material of a yellowish colour, like hard cheese, with here and there a little gritty matter; and presented no trace of normal structure. The paroxysmal mode of progress, characteristic of the usual chronic course of the disease, is also adverse to the probability of the symptoms being due to abolition of the function of the capsules, for, in that case, the frequent rallyings after severe paroxysms could scarcely take place, when the nature of the local lesion must render any renewal of function impossible. Again, in the case of other symmetrical organs, such as the lungs or kidneys, it usually happens that, if only one of the two organs is rendered functionally useless by disease, the other acquires an increased functional activity, termed compensatory; and, if life be not preserved, it is, at any rate, prolonged much beyond the average duration of life in cases in which both organs are diseased. In Addison's disease, on the contrary, in some of the very few cases in which one capsule only has been found to be diseased, the symptoms have,

nevertheless, run a course in all respects resembling the usual course of disease when both capsules are involved. Thus, in the case of a girl, aged 11, reported by Guttman in 1870, who was under observation during five months, the left suprarenal capsule only was found diseased, the right one being perfectly intact; but, nevertheless, the constitutional symptoms had been quite characteristic, and the discoloration of the skin very fully developed. A more striking case of the same class, which had been under medical observation for two years, was published by Dr. Murchison in the *Pathological Transactions* for 1866. In the year 1864, the patient, a man, aged 27, was in the Edinburgh Royal Infirmary where his case was diagnosed by Dr. Duckworth and Dr. Pye-Smith as a typical case of Addison's disease. He survived until April 1866, having been occasionally at work during the periods of remission of his symptoms. At the necropsy, only one of the suprarenal capsules was found diseased, the diseased organ exhibiting all the characteristic appearances of the capsules in Addison's disease, while the other was quite healthy.

Whatever, therefore, may be the hitherto un-discovered function of the capsules, these facts would seem to justify the conclusion that the abolition of that function, by whatever lesion it may be produced, cannot be the cause of Addison's disease. That disease being, nevertheless, invariably associated with one particular organic lesion of the suprarenal capsules, we must seek for some other means by which this lesion can give rise to the characteristic symptoms which indicate its presence. Manifestly, also, the condition to which we refer the production of these symptoms must be one which is found in connection with this one particular lesion of the capsules, and which is not associated with any of the other lesions of those organs which equally destroy their structure, but, as we have seen, do not produce the symptoms of Addison's disease.

This condition I believe to be, the extension of the chronic inflammatory process from the diseased capsules to surrounding parts, which I described, in my first lecture, as one of the characteristic features of the morbid anatomy of the disease. This extension of the inflammatory lesion of the capsules produces, as I have said, dense overgrowths of connective tissue, which form adhesions between the capsules and neighbouring organs, and which, if merely by their pressure, cannot fail to affect, in a serious degree, not only those nerves which pass in and out of the capsules, but all those which are in intimate relation with them.

Now, it is certain that the suprarenal capsules, which lie close to the solar plexus and the semilunar ganglia, receive a much larger supply of nerves, in proportion to their size, than any other organ in the body. Kolliker says that he has counted thirty-three nerve-trunks in the right suprarenal capsule; and Lobstein, half a century ago, in describing a case of tubercle of the capsules, stated that he found eight nerve-branches going from the right semilunar ganglion to the right capsule, and thirteen from the left semilunar ganglion to the left capsule. Some physiologists, indeed, believe the suprarenal capsules themselves to be ganglionic nerve-centres. Kolliker considered the cortical and medullary portions of the organs to be physiologically distinct; the cortical portions he regarded as blood-vascular glands, and the medullary portion as appertaining to the nervous system. Bergmann held very much the same opinions. More recently, Leydig has stated that the cells in the mesh-work of the medulla of the suprarenal capsules are of irregular form, and exhibit processes like the multipolar ganglion-cells of the brain and spinal cord, and further that a number of nerve-trunks which pass through the cortical portion of the capsules are lost in the medulla and do not pass out again; facts which, in his view, compel the belief that the nerve-fibres arise in these ganglion-cells, and that the medullary portion of the suprarenal capsules is essentially a ganglionic nerve-centre. Although I do not profess myself competent to pronounce an opinion on these physiological views, I think it may safely be concluded, from the observations I have quoted, that the suprarenal capsules have peculiarly numerous and intimate relations with the semilunar ganglia and the solar plexus. Dr. Habershon, to whose researches I have referred, traced also a direct communication between the suprarenal capsules and the pneumogastric nerve, and Bergmann found a direct communication between these organs and both the pneumogastric and phrenic nerves. The suprarenal capsules, therefore, are not only intimately connected with the chief centre of the ganglionic nervous system situated in the abdomen, but also indirectly through that centre, and more directly through the pneumogastric and phrenic nerves, with the cerebro-spinal nervous system.

It will readily be conceived that the pressure of a mass of hard connective tissue within and around the capsules, closely investing the nerves passing into those organs, and sometimes involving the semilunar ganglia and the solar plexus, must seriously interfere with the functions of the nerve-branches imbedded in the contracting growth.

But the injury to the nerves is by no means always limited to those branches bound up in the inflammatory new growth, for in many cases, as I showed in my first lecture, the nerves at some distance from the inflammatory tissue have been found enlarged by reason of the increased thickness of their neurilemma, which could only proceed from a further extension of the inflammatory process along their course. In several cases, it is stated that the only change discoverable in the nerves was this increased growth of hard connective tissue in their outer sheaths; but in other cases inflammatory growths have also been distinctly seen in the connective tissue sheaths of the individual nerve fibres. Thus, Hertz saw, in a case to which I referred in my last lecture, numerous oval or spindle-shaped cells, imbedded in the connective tissue between the nerve-fibres of the solar plexus and the semilunar ganglia. This undue thickening of the nerve-sheaths must necessarily tend to produce irritation, and ultimately atrophy, of the compressed medullary portions of the nerves, and these conditions have, in fact, been verified in many cases of late years.

The first notice of a morbid condition of the nerves in Addison's disease is by Addison himself, who recorded in his monograph that Mr. Quekett had found, on microscopic examination of a portion of the semilunar ganglia and solar plexus in one of his cases, that they had undergone some form of fatty degeneration. But researches into the condition of the nerves at necropsies were then much rarer than they are now, and the fullest and most accurate descriptions that I have been able to find are in recent, and mostly in foreign, cases. Hertz found in his case both the semilunar ganglia reddened on the surface, and also on section. Professor Tigri found in Burrelli's case the whole sympathetic nervous system reddened and swollen, the semilunar ganglia enlarged; and, under the microscope, both the ganglia and nerve-fibres showed remains of old and recent hemorrhages consisting of yellow granular corpuscles and of small roundish irregular bright red molecules, together with some still normal red blood-corpuscles. The cells of the enlarged semilunar ganglia, but especially of the left one, were opaque and granular, and showed no trace of nucleus, and it should be mentioned in connection with this fact that the left suprarenal capsule was double the size of the right one. Rindfleisch, again, in Kuhlmann's case, found the fibres of the two nerve-trunks imbedded in the inflammatory adhesions of the capsules to the neighbouring organs in a state of partial fatty degeneration. Van Andel states that in his case the microscope revealed atrophy of the sympathetic and of the solar plexus, with almost total disappearance of the medullary cells and pigmentation of the ganglionic cells. Boogaard found in a case of Schmidt's, which he examined, the sympathetic nerve atrophied; and Bartsch found, in a case in which the pathological conditions were very characteristic, the semilunar ganglia of a greyish red colour and the ganglionic cells almost all filled with fat, and very few of them showing any nucleus.

These numerous observations by competent pathologists leave no doubt that the antecedent probability of injury to the nerves in intimate relation with the suprarenal capsules, from the chronic inflammatory process going on around them, is borne out by the facts.

We now come to the question, how far the various symptoms of Addison's disease can be shown to be due to these morbid changes in the abdominal portion of the sympathetic and nervous system. Addison himself conjectured latterly that the intimate connection of the suprarenal organs with the nervous system had a large share in the production of the symptoms; and Drs. Wilks, Habershon, and others adopted this view, and attributed them to the implication chiefly of the sympathetic nerve. But the belief in this mode of production of the symptoms was at that time merely theoretical, and, as such, I attached but little importance to it. Of late years, however, the observations which I have detailed have convinced me that the nerves in close relation with the suprarenal capsules are undoubtedly affected in every case, to a greater or less extent, by the chronic inflammatory process of Addison's disease; and from various analogies I think it must be inferred that at least many of the more important features and prominent symptoms of the disease are produced by the morbid changes in the affected nerves.

These changes are of two kinds; and we may presume that the irritation, producing the reddening and swelling observed in Hertz's and Burrelli's cases, is the primary effect of the extension of the inflammatory process to the nerves; whilst the total impairment of their functions, which must result from the atrophy or fatty degeneration described by Rindfleisch and others, will not take place until a later period. It is obvious that irritation of the nerves, although arising from a permanent cause, would be likely to vary in degree from time to time, to subside more or less completely under favourable circumstances, and to be easily aggravated anew by comparatively trivial causes. Neither is it to be lost sight of, that fresh extensions of the

inflammatory process may at any time take place irrespective of outward circumstances. Again, according to variations in the acuteness of the inflammatory process in the capsules, the extension of inflammation to the nerves may take place much later and with much less intensity in some cases than in others.

If such be the internal conditions, it becomes no longer surprising that the constitutional symptoms of the disease should vary somewhat in character in different cases, and in the same case at different stages; nor that the course of disease should be subject to alternations of exacerbation and remission, and the paroxysms of depression come on with or without apparent cause; nor even that in some cases the symptoms should remain latent for longer or shorter periods of time, and appear to be only developed at last by some outward depressing cause. Moreover, the individual constitutional symptoms of the disease seem in great part explicable, either by the direct effects of the nerve-lesions upon certain organs, or by their reflex effects through the cerebro-spinal nervous system. The invariable listlessness and indisposition to exertion, the extreme feebleness without corresponding emaciation of the muscles, the shallow respiration, breathlessness on exertion, and small thready compressible pulse, all point to some serious interference with the functions of the nervous system; whilst the profound asthenia which supervenes before death from Addison's disease exhibits a great analogy to the collapse which follows a fatal shock to the nervous system from some severe injury. The sighing, yawning, and hicough, so frequent during the paroxysms of depression, are direct nervous symptoms; and the affections of sight and hearing, the numbness, anæsthesia and tremors, the convulsive twitches, and epileptiform and other seizures, may all be explained by reflex nervous irritation through the cerebro-spinal system. With respect to the gastric symptoms, although I am indisposed to draw conclusions from facts of which I have had no personal experience, certain physiological experiments do appear to throw light upon their production through the medium of the nervous system. Pincus states, in Funke's *Physiology*, that extirpation of the solar plexus and semilunar ganglia in animals is followed by hyperæmia of the stomach and upper part of the intestinal canal, with ecchymoses and ulcerations; whilst similar results do not follow the same operations in the abdomen, if injury to the nerves be avoided. The catarrh and other affections of the mucous membrane of the stomach, and the enlargement of the solitary glands of the small intestine, so constant in Addison's disease, would thus be shown to be due to a direct interference with the functions of the abdominal nervous centres by extension of the inflammatory process. Jaschkowitz has also found enlargement of the spleen follow the cutting through of the sympathetic—a result which would tend to explain the not unfrequent occurrence of this pathological change in cases of Addison's disease.

Although many writers have concurred in attributing the constitutional symptoms of Addison's disease to some lesion of the nervous system, they differ widely in their ideas as to the relation between the supposed nerve-lesion and the disease in the suprarenal capsules, and also as to the means by which the symptoms are produced. Risel, who, like myself, attributes the symptoms to lesions of the nerves produced by the disease in the capsules, considers that they are the direct results of excess of blood throughout the abdominal cavity—due to loss of tone from nerve-irritation—and to a corresponding deficiency of blood in other parts of the body; neither of which conditions have existed in the cases which I have examined. Amongst other recent views are those of Schmidt, Burresi, and Kuhlmann, who have concluded, from the important changes in the nerves found in their cases, that the essence or primary cause of the disease is a morbid affection of the sympathetic or atrophic system of nerves, and that the suprarenal disease is only a secondary phenomenon or accidental complication. Bartsch considers it doubtful whether the suprarenal capsules or semilunar ganglia will be found to contain the centre of the trophic nerves, which he regards as being the true seat of the disease. Rossbach, as I have said, deduces, from a case related in my last lecture, a new theory as to the nervous origin of the symptoms of Addison's disease. He attributes the symptoms altogether to functional disturbance of the cerebro-spinal system, produced by long continued grief and trouble, and bearing a close analogy to the nervous ailments which produce hysteria. He includes the two diseases, hysteria and Addison's disease, under the same head of general neuroses, with unknown anatomical causes; and concludes that, as hysteria often exists without uterine disease, so the lesion of the suprarenal capsules bears no constant relation to Addison's disease. Had the premises only been correct, it would be difficult to controvert his arguments; but he had to do, as we have seen, not with a case of Addison's disease at all, but with a case of hysterical mania, aggravated, no doubt, by the irritation of the scleroderma, and complicated with degenerative dis-

ease. Consequently, his arguments, which are convincing enough as to the origin of the symptoms in the case really before him, have no bearing whatever upon the question of the origin of the disease with which he supposed himself to be dealing.

Owing to the undue prominence which has always been given to the bronzing of skin as a symptom of Addison's disease, the character and causes of this abnormal pigmentation have been far more fully and widely discussed than those of the constitutional symptoms. Virchow, in his work on *Tumours*, expresses his belief that it is probably due to nerve-disease, not dependent, however, on the nature of the morbid process in the suprarenal capsules. Bühl regarded the pigment deposited as the result of a blood-change, characterised by deficiency of fibrine, excess of white corpuscles, and unusually dark colour of the blood. I should remark, by the way, that the four cases on which Bühl founded this opinion were all complicated with general disease of the lymphatic glands, or extensive tuberculosis, and with enlargement of the spleen, in one case to four times the natural size; and, though in some of these cases the capsules seem to have presented the appearances of Addison's disease, in one at least they did not. The other conditions are such as are well known to be associated with leukemia and melanæmia. Martineau holds that the bronzing of skin, though most frequently associated with disease in the suprarenal capsules, is really independent of its existence, because, in his opinion, it is equally common in tuberculous, cancerous, and miasmatic cachexias. Jaccoud, in his able article on bronzed skin disease in the new French *Dictionary of Medicine*, attributes the pigmentation in Addison's disease to irritation of the vaso-motor sympathetic nerves; but he considers the length of time requisite for the hypersecretion of pigment by these means to be the obvious explanation of the earlier development of the constitutional symptoms. Risel is of opinion that, although vaso-motor influences may contribute to the pigmentation of the skin, it cannot be sufficiently accounted for without the supposition of some blood-change, due to the changes in the spleen and lymphatic glands, as well as to diminished nutrition from the catarrh of stomach.

So far, however, as I have been able to ascertain, the composition of the blood does not undergo any important alteration in uncomplicated cases of Addison's disease. In all my later cases, the blood has been examined microscopically with virtually negative results. In one case, that of a woman who was anæmic, and had never been robust since an attack of scarlatina and drowsy seven years before, the white corpuscles were slightly in excess; but, in all other respects, the blood appeared normal; the red corpuscles being abundant, and forming rouleaux in the usual manner. In another of my patients, who had been in the hospital before, and was readmitted on account of extreme prostration following loss of blood from a slight wound on the head, the blood, when first examined, was not exactly normal. There was a deficiency of red corpuscles, and they did not form into rouleaux, but were scattered singly over the field. There was a large number of highly refractive nuclei, of a red colour, measuring $\frac{1}{1000}$ th of an inch in diameter, mostly lying isolated, but here and there aggregated in groups. There was no marked excess of white corpuscles. At the end of three weeks, however, when the patient had recovered her strength, the abnormal conditions of the blood had disappeared; and their temporary existence could not well be a specific result of Addison's disease, as the same appearances were verified, though in a less marked degree, in the blood of two other patients who were in the hospital at the same time, one of whom was suffering from constitutional syphilis, and the other simply from debility and anæmia. Since the delivery of my last lecture, the courtesy of Dr. Bristowe has given me another opportunity of examining the condition of the blood in a well-marked case of Addison's disease. The patient, a woman aged 48, who is at present under his care in St. Thomas's Hospital, is suffering from extreme debility and nausea, her circulation is so feeble that it was most difficult to obtain a tracing of the pulse, and she is as dark as a mulatto. Nevertheless, her blood was found, on microscopic examination, to be rich in red corpuscles, which arranged themselves freely in rouleaux, and it did not contain any marked excess of white corpuscles. There were a few of the small highly refractive bodies, described in my case, scattered singly over the field.

Dr. Thudichum, who examined chemically, for sixty-five consecutive days, the urine of a patient who died in the Middlesex Hospital under the care of Dr. Burdon Sanderson, found a great deficiency in the uric acid of the colouring matter, and he concludes that the deposit in the skin is the varying balance of a current account which may increase or decrease. Apparently, he means to infer that the abnormal deposit of pigment is an alternative result of these deficiencies in the composition of the urine, and varies in intensity according to their variations. Mr. West, in a paper read before the Royal Medical and Chirurgical Society, states the exact amount of the deficiency in the proportion of urea ex-

creted in a case of Addison's disease; and his analyses, though few in number, agree with the results obtained by Rosenstein from analyses of urine in some cases of Addison's disease in Bamberger's wards, in which he always found the urea deficient and the indican in excess.

It appears to me that no inferences can be drawn from the results of these researches with respect to the production of the bronzing of skin. I believe the deficiencies, both of uric acid and urea in the urine, to be due to the diminished functional activity, and consequent diminished waste of tissue, characteristic of Addison's disease. The excess of indican is perhaps more directly owing to altered nervous influence, for I have repeatedly found it in the urine of patients after the collapse stage of cholera, or suffering from certain diseases of the spinal cord.

My own opinion is, that the change of colour in Addison's disease is undoubtedly produced, like the constitutional symptoms, through the medium of the nervous system. The paling of the discoloration, coincidently with remissions of the constitutional symptoms, and its deepening and extension with every fresh exacerbation of the illness, appear to me to afford strong clinical evidence that these two features of the disease are referable to a common cause. Moreover, the interesting cases detailed by Meissner and others, of general and permanent darkening of skin produced by agony of mind, sudden alarms, and other violent emotions, leave no doubt of the fact that nervous influences are capable of producing abnormal pigmentation. This fact seems to me to furnish another strong presumption that the discoloration of the skin in Addison's disease is due to a morbid action of the affected nerves. There is, however, no evidence to connect it directly with any of the nerves actually involved in the inflammatory process; and I am inclined to attribute it rather to reflex irritation through the cerebro-spinal nervous system.

Although the correctness of these inferences is not susceptible of proof, without much clearer knowledge than we yet possess of the part actually played by the nerves in the physiological processes disturbed by the disease, I venture to think that the views I entertain derive considerable support from the clinical and pathological facts upon which they are based.

[To be continued.]

THE GOULSTONIAN LECTURES ON PUERPERAL FEVER.

Delivered at the Royal College of Physicians, London.

By ROBERT J. LEE, M.D., F.R.C.P.,

Assistant Physician at the Hospital for Sick Children, Great Ormond Street.

LECTURE III.—(Continued.)

It is time now to consider the application of our general conclusions to the subject of the treatment of the febrile puerperal processes, local and constitutional. The first point to which we naturally turn our attention is the determination of the conditions under which decomposition proceeds most actively, and what chemical or other agents may be employed with most certainty to arrest it. In his arrangement of what Cullen termed indication of cure, the details of treatment are divided into three classes. We have directions in the first "to moderate the violence of reaction"; in the second, "to remove the cause or obviate the effects of debility"; and, in the third, "to obviate or correct the tendency of the fluids to putrefaction". The principles which were observed in the enumeration of remedies contained in classes one and two were consistent with the views which regulated Cullen's practice in all febrile diseases, whether contagious or not. The directions contained in the third class are more in accordance with the views we now entertain of the origin of puerperal fever.

We are "to obviate or correct the tendency of the fluids to putrefaction by—1. Avoiding the application of putrid or putrescent matter by (a) removing the patient from places filled with corrupted air; (b) correcting the air, from which he cannot be removed; (c) avoiding the accumulation of the patient's own effluvia by a constant ventilation, and frequently changing the bed-clothes and body-linen; (d) removing carefully and speedily all excremental matters; (e) avoiding animal food, or correcting it. 2. Evacuating the putrid or putrescent matter already present in the body by (a) evacuating frequently the intestines; (b) supporting the excretions of perspiration and urine by (1) diluents; (2) neutral salts, antiseptics; (3) fixed air. 3. Correcting the putrid or

putrescent matter remaining in the body by diluents. 4. By resisting further putrefaction, or obviating its effects, by supporting the tone of the vessels by tonic remedies.

It does not really appear to be possible to add much to these details. We may, however, in one respect consider that we are in a much better condition to deal with puerperal fever than Cullen was, for the reason, that we have the means of putting into force his indications more thoroughly than he could. In consequence of the experiments which have been made to determine the conditions under which decomposition and the development of bacteria proceed, we are now supplied with agents which we may use to good purpose in the practical treatment of all cases in which we have reasons for thinking that there is a localised focus of infection.

These experiments are sufficiently interesting to deserve careful attention; for it seems reasonable to attach much greater importance to the arrest of the local development of bacteria than to attempt to combat their influence upon the system. There are two methods of analysis which suggest themselves for the determination of the value of any particular substance as a disinfectant. We may take a solution of a fluid containing any organic matter known to decompose under certain conditions; and, before that process has commenced, we may mix with the solution some of the substance or fluid whose properties we desire to know. By comparing the condition of the organic solution thus treated with some that has been allowed to develop bacteria freely, we may ascertain the disinfecting properties of the substance in question. The other method is the addition of solution of the disinfectant to solution containing active bacteria. By microscopical examination, we can readily ascertain from the diminished activity, or the sudden cessation of all movement in the bacteria, the influence of the substance we have employed. These are, generally speaking, the simple methods which have been adopted as the best means for affording an answer to the practical question of the value of disinfectants. Now the same test is applied in both cases; that is to say, we employ the microscope to examine what evidence there is of decomposition, or the existence of bacteria in fluids treated by the first method, as we do to ascertain the direct effects observed in the second method.

In his recent work on *Coccobacteria Septica*, Professor Billroth seems to have preferred the first plan. For instance, he takes solutions of the carbonates and sulphates of alkaline and mineral bases of definite strength, and adds them to the organic fluid, keeping side by side with the mixture, under exactly the same atmospheric conditions, and in these experiments, at the temperature of the human body, some of the unmixt organic fluid. Then, at intervals of a few hours, a few drops of each fluid are removed, and the bacteria forms which are present are registered. Thus time, to some extent, is admitted into the analysis, so long at least as there is any reason to expect the further development of bacteria in the fluid under examination.

Billroth states his general conclusions regarding certain substances as follows: "The abundant addition of carbonate of potash, sulphate of potash, sulphate of iron and copper, boracic acid, and borate of soda; chromate of potash, aqua plumbi, carbolic acid, lactic acid, and butyric acid, hardly allowed the coccobacteria vegetation to take place. . . . Hypermanganate of potash (ten grains to a fluid ounce of water) had no influence." The term "hardly" is meant to imply that, if bacteria were developed, they were only the most minute and the lowest forms, and that, beyond this stage in the process of decomposition, there was no progress. The solutions of the alkalies used by Billroth were of the strength of a teaspoonful of the salt to an ounce of water—a combination which would not be convenient as a disinfectant applied locally.

The remark, that the hypermanganate of potash had no effect, has been often made before, and only proves that the chemical theory of disinfection must not be relied upon in the estimation of the value of disinfectants. There is so little difficulty in making a considerable number of examinations in a short time by the second method, that we may easily satisfy ourselves of the various effects of different substances, but in various degrees of dilution. For example, we all know that carbolic acid has active properties, both in preventing decomposition and in destroying organic life. But, when the clinical question has to be decided, What degree of dilution may we reach without depriving the carbolic acid solution of its properties, we are obliged to resort to observation of the direct effects of solutions of different strengths on living bacteria. I have found that a convenient plan of making such observations is to place on the same slide a drop of bacteria fluid at a distance of about an inch from a drop, let us say, of carbolic acid solution; to cover them separately with films, and, while keeping the movements of the bacteria under inspection, to bring the two films into contact. The fluids beneath soon mix with one another, but sufficiently gradually to allow one to observe the effect on the animalcules. Thus,

by taking solutions of carbolic acid of graduated strength of one in 40, one in 60, and so on, up to one in 120, we can determine which is the best to employ in clinical treatment. We thus ascertain that the last of these has a distinct but not powerful toxic effect upon living bacteria; but that, beyond this point of dilution, bacteria exhibit no decided disturbance. For practical purposes, we should be inclined to use the dilution of one in eighty, as we find that it is quite powerful enough to destroy activity, and is not liable to produce irritation when applied to sensitive tissues. Similarly, we ascertain that, for the liquor sodæ chlorinatæ of the *British Pharmacopœia*, a valuable disinfectant, the dilution of the fluid with two of water furnishes us with a reliable disinfectant.

It did not appear to me to be desirable to enter at any length into the various questions which are associated with the subject of disinfection beyond determining practically the most convenient material for the purpose. At one time, it did not occur to me to make any great difference between the solutions which we accept generally as useful disinfectants; but, when attention is directed in that serious and painful disease, carcinoma uteri, to the existence of bacteria as the probable cause of unexpectedly early death, it becomes apparent that we may prevent infection, if we cannot arrest the progress of cancerous disease, by attention to details. I might have added a few remarks on one or two other substances which have appeared to be advantageously employed in combination with carbolic acid, and especially the solutions of opium. Apart from the sedative effect of the drug, it would appear that it has a special disinfecting property, not very powerful, but decidedly exhibited in such a mixture as one part of liquor opii to three of water. There is no very definite time for the formation of bacteria, as can be easily understood, in cases of septic infection: I mean to say that, in some cases, decomposition seems to proceed more rapidly than in others. From general observation in those cases of carcinoma uteri which are characterised by the most severe symptoms, the effects of infection may be observed to take place in between six and twelve hours, and those in constant attendance on such cases consider that a space of four hours is quite sufficient to allow of the generation of multitudes of bacteria. The same may be said of cases of retained placenta or decomposing uterine fibroids.

The more we attend to the satisfactory results of the practical application of the theory of infection to the treatment of symptoms, the less important does the special influence of anti-septic constitutional remedies appear to be. There are some who conceive that opium is a valuable agent in the constitutional treatment of the puerperal fever. It is not to be denied that its sedative properties may be employed to great advantage for some symptoms; but, regarded as a constitutional antiseptic, experience does not prove that it enjoys any special virtue. It may be observed that, if the introduction into the system of substances like carbolic acid be attempted on the theory that the fluids of the body may be so far impregnated with the disinfectant as to prevent the action of bacteria, it is necessary to show that such a quantity as could at a minimum reasonably effect such a purpose must be capable of being absorbed, or can be administered without injury.

On the subject of the treatment of local inflammatory symptoms, it is unnecessary to make any particular remarks. There are one or two questions of importance which I have avoided, for the reason that they are not directly involved in the question of the specific nature of the disease. One of these is the connection which we have reasons for believing exists between puerperal fever and erysipelas, and other diseases which appear to have a similar origin with it, if they be not identically the same. Many instances are on record, and many more are preserved in the recollections of experienced practitioners, of the fact, that puerperal fever, phlebitis, and erysipelas are producible from one another presumably through the medium of the atmosphere. It has been my object to ascertain whether there were any *a priori* objections to such opinions rather than to dispute the facts, or oppose them by counter-evidence. But theoretical considerations fully support the results of experience, that erysipelas and puerperal fever, and all the forms of cellulitis, may be produced from one another; and that their origin is the same. The practical study of these maladies, in their connection with one another, seems to offer the promise of explaining much that we previously failed to understand.

There is another point on which I speak with some hesitation, for the reason that I am not in a position to present conclusive evidence upon it. It refers to the question of the treatment of that complication of puerperal inflammation known as thrombosis, as well as one of the accidents of thrombosis, namely, coagulation of blood in the pulmonary artery and the right cardiac cavities, which is accompanied by a rapid fall of temperature occurring simultaneously with the distressing symptoms of this accident. This symptom has been recorded by different observers, and, as the explanation of it would not seem to be a

difficult problem for the physiologist, I shall confine my remarks to the treatment of those cases in which it may or has occurred, and to the best method of relieving the pulmonary and cardiac symptoms. The theory that thrombosis depends on spontaneous coagulation I have given reasons for believing to be pathologically incorrect, at least where we find such pathological conditions in the tissues external to the veins as to account, on mechanical principles, for the coagulation. It appears that the pulmonary and cardiac symptoms referred to are to be explained by the detachment of a portion of the coagulum in a distant vein, and its arrest in the pulmonary artery; that from this point the process of coagulation extends in the direction of the right ventricle, and gives rise gradually to the formation of the large coagulum which we find in the right cavities.

From clinical experience, we are led to conclude that, while the process of coagulation is limited to the veins of the lower extremities, and has not extended above Poupart's ligament, the possibility of a portion of coagulum being detached is very small, for the reason, as we have already seen, that by the course of inflammatory changes the current of blood from lateral vessels is prevented from impinging upon the coagulum. But, where the branches of the intrapelvic vessels join those from the extremities, there is a great probability of a portion of the coagulum being removed; and, on referring to such cases, it is found that the accident has happened when the patient has so far recovered from acute symptoms as to allow of a certain amount of movement. This suggests, of course, the necessity of great care during the period of convalescence.

The effects of thrombosis of the pulmonary artery are of such a serious nature as to make it desirable to ascertain what is the best mode of treating its occurrence. We have remarked that it is difficult to make observations intended to test the credibility of the opinions of others; and, when such a theory as that which leads to the administration of large doses of alkalies, with the object of arresting coagulation on chemical principles, was offered to us some time since, with some interest, I watched, under personal direction, the effects of this treatment, as well as the practice of others—a method of substitution which is highly conducive to impartial conclusions. These were not in favour of the theoretical grounds or practical benefits of the mode of treatment in question. Speaking from personal experience, I have no hesitation in saying that it is better to regard the occurrence of coagulation in the pulmonary vessels, and its extension to the heart, on simple mechanical principles. In proof of the correctness of this view, I considered it was justifiable, in a case of this kind, where coagulation had taken place in both lower extremities as high as Poupart's ligament, and, on one side, had entered the pelvis, to use rather active measures to relieve the cardiac symptoms. They had occurred quite suddenly during the period of convalescence, and were characterised by the tumultuous action of the heart, distress in respiration, and diminution of temperature (in this instance, from 100 deg. Fahr. to 96.5 deg. Fahr.), which are diagnostic of pulmonary embolism.

The relief which followed rather copious bleeding by the application of leeches was very considerable, both when the symptoms occurred for the first time as well as on a second occasion, when they recurred in a less severe degree a few days later. The patient ultimately recovered. We cannot, of course, decide much from one case; but it may be generally remarked that, as a local remedy for the relief of the pain which accompanies active inflammatory processes in the cellular tissue of the limbs or of the abdomen and pelvis, there is none so certain as local bleeding. We are discussing principles, however, and not details of little interest for those who regulate their practice by the scientific theories of medicine.

I have reviewed in a very general and, I am conscious, in an imperfect manner this subject of puerperal fever; I have endeavoured rather to establish some solid basis for the practical treatment of the disease than to investigate those difficult questions which are now engaging the attention of scientific observers. It may be said that, after all, we have not made any great progress since the time of Cullen, nay, since the Hippocratic period, for the theory we have been arguing for is not essentially different from the "putridity" of the one or the *σφύς* of the other.

The idea of atoms is old enough, and many, there is no doubt, may feel inclined to distrust attempts like Heiberg's to reduce all the phenomena of puerperal fever to the existence of micrococci in the various organs of the body. Those who distinguish facts from ideas will, it is probable, continue their labours, or give their encouragement to all investigations bearing upon such an important subject, feeling confident that our profession and society will some day be benefited by them.

As Professor Heiberg remarks, we are only just commencing to obtain some knowledge of a class of living organisms which threaten to

disturb the principles of medical science, and appear to endow with practical existence the ideas of the natural philosophers of bygone ages. In tracing the history of the doctrine of the nature of puerperal fever, there was, up to a certain point, no great difficulty; but now, instead of being able to regard it as a special form of disease, we must allow that it is only one of a large class. We can understand the idea involved in the explanation of its symptoms resulting from a "diphtheritic process" excited by the presence of certain forms of bacteria. We can see the importance of physiological experiments like those of Panum, which had for their object the determination of the pathological effects of emboli of different substances upon the tissues they happened to be arrested in. The local changes which followed the introduction of a globule of mercury, corpuscles of healthy pus, or decomposing fluids, were found to differ to such a degree, that we must admit the value of Panum's conclusions, that the constitutional symptoms which occur in the last instance can only be explained on the supposition of a putrid intoxication, as he terms it, of the blood.

We begin to wish to know more of the minute organisms which seem to be the chief cause of the symptoms. We find our attention being attracted to the interesting question of their generation, their various forms, and their specific characters; and we feel disposed to examine the early researches of Ehrenberg, and the later attempts of Hialler, Cohn, Lister, Billroth, and others, to reduce them into some order of classification. Such a study is, however, the work of a lifetime. As pathologists, considering the important connection between the presence of bacteria, without special regard to their species, we desire to know why an embolus of pus or fibrin may excite slight, if any, pathological changes, unless it contains micrococci, or gives rise to them by decomposition; and then we find ourselves engaged in the difficult problem of the earliest changes produced in the process of inflammation.

We begin to perceive that we are crossing the line that separates the practical from the scientific, if such a line can be said to exist; for I venture to express the opinion that you will agree with me in thinking true practical knowledge is the result of scientific conception, and that all knowledge which is not practical in no way deserves the title of scientific. I have had at command, in the preparation of these lectures, numerous works of reference, as well as opportunity of testing the truth of the theory under discussion. The difficulty has been to judge of the merits of those works rather than to analyse their contents. To sift them thoroughly, and to do them justice, and this, too, with patience and good feeling, I need hardly assure you, was a task which might have occupied a very long period of investigation.

ON THE ACTIONS OF PICROTOXINE, AND THE ANTAGONISM BETWEEN PICROTOXINE AND CHLORAL HYDRATE.

By J. CRICHTON BROWNE, M.D., F.R.S.E.,
Medical Director of the West Riding Asylum.

(Continued from page 411.)

IN reviewing these experiments, which have been briefly described, the first reflection that occurs is, that picrotoxine is an energetic poison, and that the symptoms which it produces, at least at one stage of its action, in many respects resemble those of epilepsy. It causes sudden excessive and paroxysmal discharges of nerve-centres, in which movements are co-ordinated. It induces spasms, which at first involve one group of muscles, and ultimately affect nearly all the muscles of the body, with biting of the tongue, foaming at the mouth, and loss of consciousness. It induces changes in the pulse, respiration, and temperature, similar to those which accompany epilepsy; and, when there is a cessation of the spasms, it entails some degree of paralysis or loss of muscular power analogous to epileptic hemiplegia. It leaves *post mortem* appearances in the nervous centres, which at once recall those which are seen after death in the *convulsions* of epilepsy. But, if some of the effects of picrotoxine recall the phenomena of epilepsy, there are others which recall those of tetanus. The continuous, although remittent, discharges, the drawing back of the head, and the arching of the body, are all essentially tetanic in character.

But surely these similarities in the effects of picrotoxine-poisoning to the symptoms of disease ought to enable us to ascertain upon which nerve-centres the poison of picrotoxine more particularly expends itself. It may be that it finally affects the whole nervous system, but it is obvious that it does not do so in the first instances, but invariably makes its earliest attacks upon certain definite points, and pursues its encroachments by certain definite routes. First of all,

when the poison begins to enter the blood, there is a slight degree of stupidity, lethargy, or drowsiness, corresponding with the preliminary coma observed by Dr. Roerber in frogs, connected obviously with some alteration or defect in consciousness, and therefore traceable to the cerebrum. Secondly, there is some restlessness, with unsteadiness in gait or slight impairment of power in the hind limbs, which may be ascribed to the sense of uneasiness which accompanies a state of high tension of cerebral centres, or to vertigo, or a slight nervous discharge, and to enfeeblement of the spinal cord, due to the commencing action of the poison upon it. Thirdly, there are the distinct convulsive paroxysms, which afford the true clue to the course of action which the poison pursues, and point unmistakably to one part of the hemispheres as the centre upon which it first operates. For I can perceive no justification for the theory of Roerber, that these clonic spasms are attributable to stimulation of the medulla oblongata. It is beside the question to argue that they are so because they may be produced after all the centres above the medulla oblongata have been removed. We now know that the impressions and movements which are represented in a lower centre are re-represented in a higher one, and that the co-ordinations of the pons Varolii and medulla oblongata are more highly re-co-ordinated in the cerebrum. Because the thumb and index-finger may be moved by galvanic stimulation of the median nerve, we do not argue that the movements of these parts are not ordinarily originated and controlled by volition; and so because clonic spasms may occur in rabbits by irritation of the medulla oblongata after all parts above that centre have been cut off from it, we cannot argue that such clonic spasms may not proceed from the cerebrum when it remains intact. True it is that, the lower we descend in the scale of animal life, the more have the pons and medulla to do with movement; the more do they in that direction supplant the cerebrum. But, in the case of rabbits, we have sure proof that clonic spasms, exactly like those brought on by picrotoxine, may be induced by stimulation of the cerebrum itself. Ferrier's experiments have put this beyond doubt, and have shown that convulsive seizures indistinguishable from those caused at first by picrotoxine may be caused by electric stimulation of the hemispheres; but not only so, but his experiments have afforded us a rational explanation of the march or order of advance of the motor symptoms in picrotoxine-poisoning, by connecting them with certain regions of the hemispheres. The discharge upon which these motor symptoms depend gradually increases in strength, and, as it does so in accordance with a well known law, it spreads more extensively. At first, only a few muscles, those of the head, are affected by spasm; ultimately nearly all the muscles of the body are so affected. The discharge travels laterally and longitudinally, and, in its former mode of propagation, the influence of an arterial region is, I think, plainly discernible. The spasmodic movements which are earliest noticed—twitchings of the ears and shakings of the head, dependent on the muscles of the neck—may be traced by the light of Ferrier's discoveries to a region in the lower part of the frontal lobes of the cerebrum, close to the main trunk of the middle cerebral artery, which there gives off many important branches, and affords a rich blood-supply to the corpus striatum. The spasmodic movements which are next developed in order of time—those of the eyebrows, eyelids, mouth, and fore-paws—may be localised in an area surrounding the region to which the former movements were traced, and corresponding with the distribution of the middle cerebral artery; while the movements which are still later in appearing—those of the hind legs and tail—may be referred to a more remote point close to the median fissure, and corresponding with the outermost ramifications of the same artery. It seems that a particular point may be fixed upon, in the frontal lobe, and close to the middle cerebral artery, in which the discharge originates, and from which the condition causing the discharge spreads forwards, upwards, and backwards over the hemispheres.

But, of course, violent discharges like those caused by picrotoxine have another and longitudinal mode of propagation. They would explode the centres which lie below them, even if these were themselves unsusceptible to the action of the poison; but the probability is, that these centres are themselves stimulated by the poison circulating in the blood, although more tardily than the cerebrum. At any rate, the corpora quadrigemina cerebellum, pons Varolii, and medulla oblongata are speedily drawn into the vortex of morbid perturbation. The occurrence of opisthotonos probably marks the time when the corpora quadrigemina begin to participate in the *lunatic*. When nystagmus commences, the cerebellum is implicated; and, when a sudden exacerbation in the convulsive movements takes place, it may be inferred that the pons and medulla are also engaged in the terrific discharges which ensue.

The modifications of consciousness which are associated with the action of picrotoxine are instructive as to its mode of attack. After the early lethargy or drowsiness which has been already alluded to, there

is a stage of liveliness, and it is in this stage that the first or partial fits arise. In these partial fits, affecting a few muscles, and due to discharge of but a small cerebral area, consciousness is not interrupted. The animal may be seen making efforts to oppose or counterbalance the clonic spasms, and the instant they are over it is as lively as ever. But, as the fits become more general and severe, owing to a more serious discharge of a larger cerebral mass, stupor sets in, and this advances into coma or loss of consciousness, which certainly betokens that the highest nerve-centre, the cerebrum itself, has been exhausted or destroyed by the poison. That the spinal cord does not share in that instability of nerve-tissue which is set up by picrotoxine, and is manifested by excessive discharge of energy, is, I think, shown by the fact that, throughout the whole action of the poison, there is no hyperæsthesia, but a decided blunting of sensibility in those parts from which afferent impressions have to be conducted through the cord. Pinching, pricking, or irritating the feet or tail, which in strychnia-poisoning would certainly induce spasms in animals under the influence of picrotoxine, occasion no disturbance. As will be seen hereafter, where picrotoxine is given with chloral, the hyperæsthesia which the latter induces is materially diminished. It is remarkable, however, and very significant of the mode of action of picrotoxine, that, while sensory impressions do not bring on a recurrence of the spasms, voluntary movements which imply a condition of cerebral activity, inevitably do so. When an animal that is under the influence of picrotoxine, and has suffered attacks of clonic spasms, attempts, during an interval of quiescence, to walk about, another attack is immediately inaugurated; and, when an animal actually suffering from slight clonic spasms, without loss of consciousness, makes any spontaneous movements, the spasms are at once exaggerated. There are besides, perhaps, certain areas or epileptogenous zones, the sensory impressions or muscular sensations from which have the power of starting clonic spasms. In a guinea-pig that had gone through three fits, convulsions could not be reinduced by loud noises, by blowing upon the face, nor by pinching of the paws, but were at once brought on by squeezing between the finger and thumb the skin and muscles of the cheek.

If further corroboration of the view, that picrotoxine acts upon the cerebrum, were wanted, it might be found in the fact, that the convulsions which it evokes are so severe and so long-sustained. Such an immense volume of movement implies the evolution of an enormous quantity of molecular force in the nerve-centre in which it originates, which must, therefore, be a nerve-centre of a highly elaborate structure, richly endowed with grey matter or explosive material. But there is no nerve-centre except the cerebrum which adequately conforms to this condition, and it may legitimately be inferred, therefore, that it is the cerebrum that has to do with the production of the voluminous convulsions in question.

The mode in which picrotoxine acts upon the cerebrum can only be a subject of speculation. The alteration in function which it occasions is evidently, in the first instance, in the nature of excess. A state of instability of nerve-tissue is set up, an undue proportion of force is stored up and expended. This is, in all probability, due to some change in the composition of the vesicular matter. One of its ingredients may be replaced by some chemical congener, the result being a more explosive compound; or its nutrition may be abnormally hastened, owing to intense hyperæmia. Whatever the nature of the alteration in the vesicular matter, occasioning its excessive explosiveness, may be, there seems no room to doubt that picrotoxine has a special elective affinity for the vesicular neurine of the cerebrum. But, beyond this, it is not necessary to suppose that the elective affinities of that agent are stronger for the nerve-cells and fibrils of one district of the cerebrum than for those of another. The succession of the symptoms arising out of irritation of the cerebrum may be accounted for without resorting to any such assumption. The picrotoxine, when injected under the skin, is taken up gradually, and will then be carried indiscriminately throughout the body. At first, only a small quantity, in a combined or uncombined state, will reach the cerebrum, and of that small quantity a large proportion will be conveyed by the main artery of the brain, the middle cerebral. The proportion thus conveyed will be seized upon by the most proximate parts, which have strong elective affinities for the picrotoxine, and which draw their blood freely from the expansions of the middle cerebral: and only when, with the progress of absorption, the proportion of picrotoxine in the blood is increased, will other circles of cerebral matter obtain a supply of the poison. Then a certain time must always elapse between the application of any discharge-producing agent to vesicular matter, and the consequent discharge. When the surface of the hemispheres in rabbits is stimulated by electricity, twenty seconds frequently intervene between the withdrawal of the electrodes and the initiation of the resultant fit. And the length of time that elapses between stimulation of nerve-

matter and discharge is always in the inverse ratio of the functional activity of the part stimulated. If the functional activity be high, the time is short; if it be low, the time is long. Now, the most functional active parts of the cerebrum are those in which the most voluntary movements are localised, and therefore, in the rabbit, the most functionally active part must be that in which the movements of the ears and mouth are localised; but that part is in immediate proximity to the middle cerebral artery, and is indeed that which would first receive the poison; so that that part will inevitably begin to discharge itself earlier than any other centre, both because it had priority in the reception of the poison and because it is, by virtue of its superior functional activity, more quickly susceptible to its influence. Next to that part, these centres lying immediately around it, and controlling the second most highly differentiated group of movements, those of the eyelids, shoulders, and fore-paws, would succumb to the action of the poison, which would reach them a little later than the mouth and ear-centres, and would require a little longer time to bring them to high tension and discharge. Beyond these centres, another group more remote and less highly differentiated would be a stage later in being brought into play. Upon all centres the poison would act with a celerity and energy proportioned to the amount of cineritious substance which they contain; for the cineritious substance is far more vascular than the medullary, and is more naked and exposed, being shielded by no isolating sheaths, and is hence first acted on by any agent in the blood which is capable of changing the molecular state of nerve-matter.

The secondary action of picrotoxine upon the cerebrum after the stage of molecular disturbance and excitement is over, places it in a state of disability and paralysis. There are defect of consciousness or more or less coma, and loss of power over the muscles. Function is in abeyance. If the dose of the poison have been very large and uncounteracted, the nerve-tissue may be destroyed; the nerve-vesicles may have been irreparably damaged; the nerve-fibrils made impermeable; or a clot may have pressed upon or broken up the brain-substance. But, when only smaller doses have been received, the nerve-tissue is not permanently injured; it has only been exhausted by the strong discharge, and, after a period of repose, it resumes its functions. The exhaustion, however, or rather its manifestation, may be much enhanced by the encephalic congestion, which invariably results from picrotoxine poisoning.

In the action of picrotoxine upon the pupils in rabbits, there is nothing very distinctive. Until convulsions set in, the pupils retain their average dimensions; then, however, they commonly become somewhat dilated, contracting again during the period of clonic spasm. The state of the fundus of the eye during picrotoxine-poisoning was investigated in 1872, by my former colleague Dr. Aldridge, and was found to consist in hyperæmia.

One very constant effect of picrotoxine is to stimulate the peristaltic action of the alimentary canal. Under its influence, the bowels are almost always evacuated in the freest manner, and sometimes repeatedly, the motion being generally moist and pulpy. This change in the character of the motions, I am inclined to attribute to defective absorption, owing to the increased haste with which its contents are passed down the intestine, rather than to any augmentation in the intestinal secretions. For, although picrotoxine has been described as a gastro-intestinal irritant, I have never been able, when it is administered hypodermically, to find any reddening of the mucous membrane of the stomach or bowels, or to perceive any indications of an irritative action upon those parts. I have never seen it cause vomiting when given hypodermically, and I cannot help thinking that some observers, when watching its effects, have mistaken emprosthotonos for retching. The bladder is generally emptied more than once during the action of picrotoxine, and the flow of urine is sometimes apparently increased in amount. The flow of saliva is always greatly augmented, and the salivary glands are obviously subjected to stimulation, which is not ascribable to the violent action of the muscles in their vicinity, as the increased secretion often precedes the involvement of these muscles in the convulsive action. The modifications of respiration and cardiac action, induced by picrotoxine, can only be stated in general terms, as, during violent convulsions it is impossible to count pulsation or respiratory movements without the use of restraint, which would vitiate the results. It is certain, however, that the movements of the thorax and heart are at first greatly accelerated by picrotoxine, and continue to be very rapid until the spasms set in, when the respiratory movements are often irregular, and the heart's impulses are exceedingly feeble. When coma supervenes, the respiration becomes slower, and the cardiac contractions weaker and more unfrequent. After death, the lungs are not engorged nor even congested, but the right side of the heart is always distended with blood, and the left side is only partly contracted and contains blood also.

The action of picrotoxine upon the temperature of the body is very uniform and constant. Immediately after its administration, there is a slight rise, attributable to the agitation attending the exhibition of the drug, and subsequently there is a steady fall, amounting sometimes to as much as seven or eight degrees of Fahrenheit's scale, but usually more moderate, and not at all comparable with the fall which is caused by many other agents. In some instances, trifling fluctuations in temperature occur, a slight rise attending each fit, and a heavy fall marking each interparoxysmal period. As a rule, however, the fall is a steady one, and becomes slower in proportion as it recedes from the normal standard. No close relation exists between the dose of picrotoxine and the reduction of temperature, as that is sometimes as great after a small and non-fatal, as after a large and fatal dose.

The observations made on the actions of picrotoxine may be summed up in the following conclusions.

1. It is an energetic poison, and acts chiefly upon the encephalic centres.
2. It causes first, sudden excessive and paroxysmal discharges of certain gradually widening areas of the cerebrum; secondly, continuous but remittent discharges of the corpora quadrigemina, cerebellum, pons Varolii and medulla oblongata; and, thirdly, exhaustion of all the centres discharged, coma, and death.
3. It diminishes the activity of the reflex centres, and general sensibility, by paralyzing the posterior columns of the cord and the peripheral sensory nerve.
4. It first quickens, and finally retards, the movements of respiration, and the cardiac contractions.
5. It produces a decided lowering of the temperature of the body.
6. It increases the secretion of the salivary glands, and the peristaltic movements of the intestines.
7. It causes great venous congestion of the encephalon, and occasionally extravasations of blood upon its surface.

(To be continued.)

ON ARTERIO-CAPILLARY FIBROSIS.*

By RINGROSE ATKINS, M.A., M.D.,

Assistant Medical Superintendent of the District Lunatic Asylum, Cork.

DURING the short time I hope to occupy your attention this evening, I purpose considering the subject of Arterio-Capillary Fibrosis, as it occurred to me that a brief examination of this—if I may use the term for the time being—popular subject, illustrated with such specimens which I, from the limited sources at my command, could bring forward, might not prove uninteresting to those who, from the various engagements of active professional work, may not have leisure to inquire into the subject for themselves, withdrawn as it is from the beaten path of medical literature.

The first notice of this novel doctrine regarding the changes in the vascular system which are found to accompany chronic Bright's disease appeared in a paper by Sir William Gull and Dr. Sutton, read before the Royal Medical and Chirurgical Society, and published in the fifty-fifth volume of the *Transactions* of that Society. In this paper, the authors allege that the renal lesion in chronic Bright's disease, with contracted kidney, is only a part and parcel of a general morbid change throughout the vascular system, characterized by the deposit of a finely fibrous or granular material, to which they have given the name of hyalin fibroid, outside the muscular layer of the small arterioles and capillaries, and in some cases by a thickening of the inner coat also, accompanied generally by hypertrophy of the heart, and in many cases by a "fibrosis" of other organs of the body also. As the renal lesion is, from the effects it produces, be they primary or secondary, the most important element in the affection, I think it may be interesting, in the first place, to briefly examine the morbid histology of that organ when affected with the disease under consideration. In order to facilitate this, we may conveniently consider the morbid changes under three heads, as occurring—1. In the tubes; 2. In the intertubular tissue; 3. In the vessels. The changes occurring in the tubes are of two kinds; namely, those taking place (1) in the epithelium, and (2) in the basement-membrane. The changes in the epithelium are essentially of a degenerative nature; in the earliest stages of the disease, the cells appear to be shrivelling up, becoming granular, and losing their regularity of outline; and, as the morbid process progresses, they become transformed into masses of granules, filling up the tubes, and being cast out in the urine in the form of the well known "granular casts," leaving

the tubes bare and desquamated. These different degrees of degeneration are well seen in this drawing taken from the specimen under No. 1 microscope (Fig. 1), which also exemplifies the other changes taking place

Fig. 1.—Transverse Section of Kidney. (Granular contracted)—in Glycerine— $\times 400$.

A. Renal Tubules filled with "degenerated epithelium". B. Fibroid material surrounding Tubules. C. Renal Tubules (desquamated). D. Renal Tubules filled with granular debris.

in the organ, and which was taken from a typical case of this disease. The basement-membrane is found to be thickened and rendered coarsely fibrous, the desquamated tubes appearing as rings of various shapes and sizes in transverse section. Passing now to the intertubular tissue, we find it to be enormously increased in many parts of the organ, surrounding and separating the tubules, and rendering their outline irregular and distorted, appearing in some parts granular, like ground glass, and in others coarsely fibrous and wavy. This substance also exists in great density around the Malpighian bodies, and attains its maximum about the arterioles, to which we next come. The walls of these, which are of primary importance regarding the present subject, are found much thickened, the lumen often contracted, and their course tortuous and twisted. This specimen shows a transverse section of one of these vessels, its walls thickened and surrounded with the fibroid material above mentioned, which is also seen between the tubules in the drawing of the transverse section of the kidney.

Having thus glanced at the anatomical condition of the kidney, I will next, leaving until the sequel the pathological explanation of these phenomena, proceed to consider the changes occurring in the arterioles throughout the system generally, first detailing the observations of Sir William Gull and Dr. Sutton, and then examining, on experimental and pathological grounds, the correctness and tenability of their views. Sir William Gull and Dr. Sutton, at the commencement of the observations from which they finally evolved their theory of the so-called arterio-capillary fibrosis, considering the pia mater as the most suitable, both from its transparency and facility for microscopical examination, chose that membrane for the subject of their researches. Portions of the membrane taken from the bodies of those who had been the subjects of chronic Bright's disease, with contracted kidney, having first been tinted with carmine and mounted in glycerine and camphor-water, were then examined with powers ranging up to 750 diameters, and the following appearances were observed. In the larger vessels, where the three coats are distinct, the inner one was found in some cases to be thickened to a marked degree, and to have a fine fibrous or molecular appearance. The muscular coat was also found variously altered, the nuclei not absorbing carmine as readily as in healthy vessels. In some of the vessels, this coat was found to be relatively increased, while in others it was decreased, the nuclei being irregular in shape, and often

* Read before the South of Ireland Branch.

reduced to globular bodies, like fat-granules; and nowhere, it is stated, can the evidences of muscular hypertrophy described by Dr. Geo. Johnson be found. Outside the muscular coat, and immediately in contact with it, was a more or less "hyalin" formation, closely resembling the finely fibrous structure found in the kidney. This formation outside the muscular coat varied according to the size of the vessel examined, being in the larger arterioles more fibrous-looking, while in the smaller ones and in the capillaries the granular or hyalin appearance predominated. In this hyalin fibroid substance, ill-defined nuclei or corpuscles are found irregularly disposed, and wanting the regular arrangement of normal elements.

The following is a summary of these microscopical observations.

1. In chronic Bright's disease, with contracted kidneys, the arterioles throughout the body are variously altered.
2. This change is due to hyalin fibroid formation in the walls of the minute arteries, and a hyalin granular change in the corresponding capillaries.
3. This change occurs chiefly outside the muscular layer, but also in the tunica intima of some arterioles.
4. The degree in which the affected vessels are altered, and the extent to which the morbid change is diffused over the vascular system, varies much in different cases.
5. The muscular layer of the affected vessels is atrophied in a variable degree.

In order to examine how far this morbid change existed alone, the pia maters of a number of persons who had died of various diseases were examined, and in some the same appearances were observed, while in others no change had occurred; further, the hyalin fibroid change was not found in the bodies of those who were killed accidentally, or who had died of phthisis, and other diseases not allied to the cachexia of the so-called chronic Bright's disease, with contracted kidneys.

Having thus detailed the conclusions arrived at by Gull and Sutton, based for the most part on microscopical investigation, I will next proceed to examine on the same ground the correctness of these views. In an able paper written in answer to that of Gull and Sutton, Dr. George Johnson alleges that the hyalin fibroid material above described is entirely artificial, and produced by the distension of the outer elastic coat of the artery by the glycerine and camphor-water in which all the specimens were mounted previous to being examined. With the view of testing this for myself, I instituted the following series of experiments and observations. Having procured specimens of pia mater from subjects who had not died of chronic Bright's disease, I examined several portions in the fresh state, immediately on removal from the body, without any tinting, and immersed merely in water. I found the walls of the arterioles to be of normal thickness, and not affected with any hyaloid change. I then placed the same specimens, one portion in glycerine alone, another portion in glycerine and camphor-water, and a third portion in the last mentioned fluid acidified with acetic acid. I had also other specimens tinted with carmine mounted in the same fluids. After remaining for some time thus prepared, I again examined them, with the following results. Of the portions placed in pure glycerine, the first examined showed no change; the walls were not visibly affected, either as to structure or size. This preparation is here delineated, magnified 400 diameters, and you will be able to examine it for yourselves under the microscope by and bye. The next preparation, also in pure glycerine, which had been taken from a different subject, and also tinted with carmine, showed, on examination, very different appearances; the muscular nuclei were, if anything, more distinct than when examined in water, and outside, and in direct contact with this layer, was a fine hyalin formation, very slightly wavy, hardly at all coloured by the carmine fluid, extremely transparent, and evidently due to the distending action of the glycerine on the outer elastic coat of the vessel. The appearance presented almost exactly corresponded with the description and drawings given by Gull and Sutton, only being of less extent; the specimens which had not been stained gave precisely the same results. This preparation, which you can also examine, is figured in this drawing, magnified 300 diameters, which is quite a sufficient degree of enlargement. No drawing, however, can accurately portray the delicately fine appearance presented by the preparation itself.

Having thus proved that glycerine alone is able, though perhaps not in every case, to give rise to the hyalin formation, I next proceeded to the examination of the specimens mounted in equal parts of glycerine and camphor-water; in all, both tinted and natural, the hyalin appearance was present, and to a greater extent than in the last series, the marked points of difference being in the greater thickness of the distended outer coat, and in the diminished distinctness of the muscular nuclei, which appeared as if fewer in number and more separated. In neither series was there any appearance of distension or thickening of the tunica intima. This drawing, taken from a preparation mounted in this way, shows these appearances, the apparent

thickening of the outer coat, and the indistinctness of the muscular layer. Having thus disposed of these two series, I then proceeded to the third; namely, those put up in glycerine and camphor-water acidified with acetic acid, and here the appearances in question had attained their maximum. The entire thickness of the wall of the vessel, especially the smaller ones, appeared greatly increased, and almost perfectly transparent and hyalin; the muscular nuclei were also rendered clear, and appeared as outlines of various forms scattered through the thickened walls of the vessels. In the larger arterioles, the transverse markings were rendered sharper, more distinct, and highly refractive. I have in this drawing (Fig. 2) shown the changes

Fig. 2.—Arteriole of Pia Mater (in Glycerine and Camphor Water) $\times 400$.
E. "Hyalin Fibroid": formation artificial. F. Muscular Layer—very indistinct.

produced by these reagents, the figure representing a rather large arteriole, in which the transverse markings are abnormally distinct. These appearances are certainly due to the ready absorption of, and consequent distension by, the glycerine and camphor-water, added to which is the clarifying action of the acetic acid on the muscular elements present. As a confirmative proof of this, I neutralised the acid with ammonia, and, on a second attempt, succeeded in producing a shrinking and contraction of the distended elastic coat.

The drawing I now hold in my hand faithfully represents the appearances produced in the natural unstained membrane by the action of the acidified glycerine and camphor-water solution, and its neutralisation by ammonia. On this side are the vessels in their normal state, examined in water immediately after being removed from the body; and on the opposite side are the same vessels acted upon by the reagents, showing to my mind in the clearest manner that, whether the so-called "hyalin-fibroid" formation exists as a true morbid product or not, it can be artificially produced by the fluids in which the specimens are immersed. I have also examined vessels prepared in spirit, but, I may say, with mostly negative results; the only appearance produced being a greater distinctness of outline and corrugation of the outer coat.

From these facts, we must necessarily come to the conclusion, apart even from any positive evidence that may be forthcoming, that any deductions based upon the examination of specimens mounted in any of these ways are untrustworthy and open to doubt, and afford negative evidence of the occurrence of this peculiar morbid condition.

Turning now to the examination of the vessels in cases of chronic Bright's disease with contracted kidney, we have here some instructive examples. This drawing (Fig. 3), taken from a transverse section of an

Arteriole of Skin (outer coat distended, muscular layer hypertrophied) in Glycerine $\times 100$.
H. Outer Coat. I. Muscular Layer.

arteriole of the skin from a subject with granular kidneys, shows first the muscular coat greatly thickened and deeply stained. Outside this is a

fibroid and somewhat transparent membrane, less deeply coloured, and equal in thickness to the layer within it. This preparation being mounted in glycerine for some time, I naturally infer from the experience gained by the above experiments that this external membrane is nothing more than the distended elastic outer coat of the vessel. That the inner thickened portion can be nothing else than the muscular layer hypertrophied, is evident both from its anatomical form immediately within the elastic outer coat, which is here rendered so evident, and also from the radiating appearance peculiar to the muscular coat, which is present in some parts. In order to ascertain correctly the actual degree of hypertrophy present, I made comparative micrometric measurements, and found that the muscular wall of the diseased vessel was almost twice as thick as that of a healthy cutaneous arteriole of the same size and character.

Now, returning to the arterioles of the kidney, we find the same results to obtain even to a greater extent than in the skin; the canal of the vessel being very much reduced in calibre, owing to encroachment on it by the hypertrophied walls. The outer coat is not here seen, owing to its almost entire absence from the walls of the vessels of this organ.

We thus see that a true morbid thickening of the walls of the vessels does exist in this disease; and its presence may be demonstrated, along with the hyalin formation produced by the action of the glycerine mounting fluid. Whether a real thickening of the outer coat or morbid deposit in it does exist in chronic Bright's disease with contracted kidney, in company with the muscular hypertrophy, is still to my mind *sub judice*; and it is only by endeavouring to examine carefully specimens of vessels taken from persons who had laboured under the disease in question, in fluids which will not act as above on the tissues under observation, that we can ever hope to arrive at the truth.

Leaving now the experimental side of the question, let us turn and examine briefly the pathological grounds for a belief or disbelief in the occurrence of "arterio-capillary fibrosis" as a morbid state *per se*. When speaking of the morbid histology of contracted kidney, I deferred the pathological explanation of the appearances there described to a later period; and I will now proceed, with your permission, to shortly discuss this, upon which the whole question, looked upon from a pathological point of view, hinges.

Upon this point, there are at present three rival theories, each maintained by men of equal repute, and on arguments which appear in each case almost convincing. Gull and Sutton, and their followers in this controversy, hold that the renal affection is only part and parcel of this general morbid change which they allege to have discovered, and explain its almost constant occurrence in the kidney by stating that it commonly commences there, but not necessarily so, as it may begin primarily in other organs. Dr. Dickinson and his party, while agreeing with Gull and Sutton as to the occurrence of this fibrous material in the organ, differ from them in maintaining that the change is here primary, and due to an "intertubular deposit" being, in fact, a true cirrhosis of the kidney. In opposition to these views, Dr. George Johnson and a large number of pathologists deny that the appearances, which they both similarly describe, are due to this intertubular deposit, be it primary or secondary; and assert that the changes produced are the result of a wasting and shrinking of the tubules from primary intratubular changes. From the facts which I have already adduced, the theory of Gull and Sutton cannot be at present accepted, as, if their views of a primary arterio-capillary fibrosis are fallacious, it naturally follows that a diseased condition which is part and parcel of that change cannot be maintained. With regard to the relative merits of the other theories, many cogent arguments are brought forward on either side; but, as I fear I have already overstepped my time, I cannot now discuss these as I should wish. Suffice it to say that the theory of a primary intratubular change appears to have the greatest weight of evidence.

Turning once more to the arterial changes, let us shortly examine, on pathological grounds, the correctness of the theory of a primary arterio-capillary fibrosis. As I have already shown, it is on experimental grounds trustworthy; so also on pathological ones it is fallacious and doubtful. Supposing even that the appearances present in the pia mater examined were morbid, and not probably artificial, does it not appear that such results, as betokening a general morbid condition, are unreliable in the extreme, as the pia mater, from its peculiar office of affording a nidus or matrix for the support of the enormous number of vessels ramifying upon it, must often be the seat of local changes occurring in these vessels, the result of chronic congestions, such as may occur in emphysema, heart and brain disease, and notably in that form of renal lesion in question; such diseases being present in many of the cases examined by Gull and Sutton, and placed amongst the list on which they ground their doctrine? As an illustration of this, I have here a drawing of a vessel of the pia mater from a subject who had been for

many years insane, and whose brain showed the appearances of former congestions. Again, in certain cases, where thickened arterioles were coexistent with hypertrophy of the heart without any affection of the kidneys, brought forward by Gull and Sutton as proof of the independent existence of this morbid change apart from renal disease, the cardiac hypertrophy was due to other and extraneous causes, such as degenerative changes in the larger arteries and chronic disease of the lungs. And, finally, the authors in one part, having stated that atrophy of the surrounding tissues is an accompaniment of the hyalin fibroid condition, yet describe cardiac hypertrophy as one of its most prominent conditions. From these and other facts, it is evident we must look further for some better theory to explain the undoubted thickening which occurs in many cases of chronic Bright's disease in its advanced stages; and this, I think, will be found in that of "muscular hypertrophy", an example of which, and the histological appearances present, I have already described. And it now remains to offer the pathological explanations which have been given by its original discoverer, Dr. Johnson, and others who have followed him. His explanation is as follows. "In proportion to the destruction of the renal gland-cells, and the consequent diminution of the secretory power of the kidney, there is less demand for blood to be acted upon by the gland; the small arteries, by virtue of their muscular coats, consequently contract upon their contents, so as to maintain the balance between the blood-supply and the diminished secretory action of the kidney. This continued over-action of the small arteries in antagonism to the heart results in hypertrophy of their muscular walls: as it is now well known that the minute arteries through the body have the physiological power, by the contraction of their muscular coats, of diminishing and retarding the blood-stream, and adapting to the different organs the amount of blood required by them at different periods, the heart itself finally, by its resistance to this retarding force, becoming in turn hypertrophied." If this explanation be correct, it follows that the renal condition in this disease is primary, the arterial secondary, and the hypertrophy of the heart tertiary. Traube and Ludwig, while agreeing in the main with Johnson in this explanation of the muscular hypertrophy, differ from him in considering that, besides a true hypertrophy, there also occurs a degeneration of the coats. This he explains by the fact that the heart and minute arteries, acting against each other, lead to a distension of the elastic vessels between them, and so to atheroma. I may add that Lamberger and others dispute this explanation of Johnson, asserting that the hypertrophy develops in a stage of the disease when no obstruction of any importance to the circulation of the kidney exists. A more extensive collation of facts will be necessary to decide this disputed point; but at any rate, whatever be the explanation, there can be no doubt of the existence of hypertrophic thickening of the minute vessels throughout the body, but whether accompanied by other changes has not, in my opinion, yet been determined.

In conclusion, I have to thank you for the kind attention with which you have listened to this, what, I fear, to some must have appeared a long and tedious paper. The nature of the subject, however, from the various and opposite views brought to bear on it, must be my apology. It is in itself a subject of narrow limit—in fact, a microscopic atom of our science, which requires a high power, as it were, for the unravelling of its mysteries; and it is only by patient investigation and laborious study that a true understanding of its complex nature and intricate working can ever be arrived at; and it is with an earnest hope that, as opportunities for such study present themselves, they may not be lost sight of, but carefully examined and worked out, that I have brought the subject before you.

NATIVE OIL OF MALE FERN.

HAVING failed lately in several cases in expelling the whole of the tænia solium by the ordinary foreign oil of male fern, I was induced by Messrs. Wyley and Co. of Coventry to give their native oil a trial. I have used it now in seven cases, in six of which it has proved entirely satisfactory; the seventh case being that of a young child, in which it was not retained many minutes. I administer it in the following manner. Two days previously, I give a brisk aperient, and order a strictly fluid diet. On the evening of the second day, I direct about two ounces of new milk to be brought in a wide mouthed bottle, to which I add for an adult male two drachms and a half of oil of male fern, agitating the oil and milk, which readily mix, and direct the dose to be taken early in the morning fasting, and to be followed by a dose of castor-oil in three hours. In all six cases, the worm has been expelled whole in from four to six hours. Three of the cases had been treated in the same manner previously by the foreign oil, kamala, and other anthelmintics, but with no more effect than to bring away a few feet minus the head.

DR. HERBERT C. P. MASSER.

(Brit. Med. Journal.)

OBSTETRIC MEMORANDA.

AFFECTION OF THE RIGHT ARM COMING ON DURING PREGNANCY.

THE following brief notes of a nerve-affection dependent on pregnancy may be interesting to the readers of our JOURNAL, as I believe it is in some respects unique. Mrs. C., on May 22nd, was confined with her third child. The labour was natural, save that what appeared the ordinary bag of membranes presented unbroken at the external outlet. This, however, came away perfectly free, and was evidently the product of a false conception. The child was afterwards born with the usual head presentation. She then stated that when she was about four months advanced in pregnancy, she awoke one night with a severe pain in the back of the right hand, and front of fore-arm and arm as far as the shoulder; the limb was not tender to the touch. At the same time there was great swelling of the veins along the painful track, which disappeared, as the pain disappeared, and was succeeded by numbness in the parts affected. This pain came on at intervals during three months, being most severe at night. It was always accompanied by a swelling of the veins, and always left a numbness behind, with stiffness of the fingers on closing the hand. It then suddenly and entirely disappeared, but the numbness remained constant up to the date of confinement. Since then, the numbness gradually disappeared. In all other respects her health was good throughout her pregnancy, and she had no pain or swelling of either lower limb. She had never previously had a similar attack. The sudden onset, and equally sudden disappearance, of the pain, its severity and spasmodic character, the accompanying venous congestion, and the subsequent numbness, all point to a neuralgic origin; and, looking to the connection between the roots of the phrenic and brachial plexus on the one hand, and the communication that exists between the great abdominal ganglia of the sympathetic and the spinal system of nerves on the other, there is no difficulty in accounting for all the symptoms by the theory of uterine pressure and irritation. But the interest of the case clinically lies in the fact, that the affection was entirely limited to one of the upper limbs, the general health remaining good in all other respects.

JOHN CROSS, M.B. Camb., 2, Spital Square.

SURGICAL MEMORANDA.

SPINA BIFIDA.

IN the BRITISH MEDICAL JOURNAL of March 20th, Dr. Morton, referring to Mr. J. E. Burton's case of spina bifida, reported in the JOURNAL of the 13th March, says: "It belongs to a class of cases all but absolutely hopeless, in which the lower limbs and lower part of the trunk of the body are paralysed, and the infants usually die in a few days. Instances of longer survival are rare indeed, and I am not aware that there are any on record in which the paralysis was so very extensive as in Mr. Burton's case." I have at the present time under my care a case precisely similar to the one described by Mr. Burton, and the child is now eleven weeks old. It was born on December 7th, 1874, and was a healthy looking and well made female child, down to the seat of the cleft in the spine. Over the two upper lumbar vertebrae was a fluctuating tumour about six inches in circumference, having a well marked pedicle. The tumour had two small superficial ulcerations, from which a thin ichorous discharge exuded, the remainder of its surface was covered by a somewhat dense opaque looking integument. There was talipes varus of both feet, the plantar surfaces being accurately opposed to one another, and quite flat and smooth, as if they had been kept in perfect apposition during the period of gestation. Both legs were flexed upon the abdomen, and had an arched appearance with the concavity towards the abdomen. There was no appearance of the natural fold of the buttocks or of the popliteal space. The whole length of the legs from the tuberosities of the ischia to the heels of the feet presented a smooth unbroken convex surface. There was paralysis of the sphincter ani. This state of things continues. I did not consider the case at all fitted for operative interference, and in this view my partner Mr. Marsack concurred. At the present time, the tumour and the lower limbs are much in the condition I have here described. There has been no increase in the size of the tumour, rather a diminution. The child for the first month appeared to thrive; since then, it has gradually wasted, until now it is quite a skeleton. There have been no convulsions, but it has suffered severely from eczema of the head, face, and trunk. The surface of the tumour has continued to give forth a thin and sometimes offensive discharge. This case appears

to be in all respects similar to Mr. Burton's, except that my patient has no rotation outwards of the legs. I could not see any object in attempting to cure the spina bifida, as there appeared to be no prospect of relieving the distorted and paralysed lower limbs; and I felt, as did also the parents, that the sooner the poor little deformed creature quitted this world the better. Probably the injection of iodine, as in Mr. Burton's case, would have expedited matters, but possibly it might have prolonged the child's life, which was not an issue to be desired.

FREDERICK MANSEY, Tunbridge Wells.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

ALL SAINTS INSTITUTION, GOWER STREET.

CASES OF OVIARTOMY.

(Under the care of Dr. GRAILY HEWITT.)

IN the BRITISH MEDICAL JOURNAL for June 28th, 1873, page 729, were reported cases of ovarian disease treated by Dr. Graily Hewitt at the All Saints' Institution up to that date, including seven cases in which ovariectomy was performed. The following is an account of the operations of ovariectomy Dr. Graily Hewitt has performed in this institution from the above date to the end of 1874. The new cases are seven in number.

CASE VIII. *Enormous Multilocular Cystic Tumour of Ovary: Previous Tappings; Ovariectomy: Death* (Reported by Mr. J. R. CROCKER).—The patient, M. A. G., aged 53, had been under the care of Dr. Mercer Adam of Boston. She had had ten children. The abdomen began to enlarge two years ago. A tumour was found to be present nearly a year ago. A first tapping was performed in March 1873, and four pints of a thickish fluid were removed. A second tapping was made in June 1873, when about double this amount was removed. On admission on August 6th, 1873, the abdomen was very large, measuring fifty-one inches in circumference, filled by a tumour, which gave well marked fluctuation in all directions. There was oedema of both feet; locomotion was almost impossible. The urine contained no albumen. She had emaciated lately.

Ovariectomy was performed on August 9th, 1873, in presence of Professor Lazarewitch, Dr. Slavjanski, Dr. Mercer Adam, and others; Mr. Manning and Mr. J. R. Crocker assisting. Ether was given by Mr. Rigden. The tumour was found to be composed of one very large cyst and about a dozen smaller ones, with many others still smaller. The contents of the cyst varied in character; one part of the tumour was semi-solid, and of the alveolar character. Anteriorly, the cyst-wall was very thin, and almost universally, though slightly, adherent; and above, it was covered for some distance by omentum. The adhesions were for the most part easily broken down, but some of them were separated by the actual cautery. The first incision was short; but it was necessary to carry it above the umbilicus to reach the adhesions. The secondary cysts were broken down by the hand, and the tumour finally turned out. A small cyst obscured the pedicle, and surrounded it. The pedicle was very short, and was torn a little in obtaining access to it. The first ligature consequently slipped a little, and bleeding occurred; but it was shortly secured by tying low down in two portions. A portion of the omentum was removed by the actual cautery; but bleeding vessels in it had still to be secured by ligature. The peritoneal cavity was cleaned out as effectually as possible by sponges. The operation, though tedious, was borne well. For the next five days, the patient did pretty well, the temperature being generally under 101 deg., and the pulse 98 to 100, and she had begun to take food by the mouth. The wound appeared to be healed, except at one point, where a little pus exuded. The deep sutures were removed on the sixth day. On the following day, the temperature rose to 103 deg., the pulse 140; and there was restlessness, also pain above the right groin. A vaginal examination was made, but no indication of the presence of collection of fluid in Douglas's pouch was found to exist. The unfavourable symptoms persisted, and death took place on August 18th, nine days after the operation.

The *post mortem* examination showed that the wound was almost completely united, except just below internally. At this point, there was peritonitis extending to the right iliac fossa, along a coil of intestine which was partly adherent to the wall. The inflammation extended to Douglas's pouch, in which was about an ounce and a half of thick puriform fluid with flakes of lymph. The ligature on the pedicle

on the left side was not encysted: the parts near it were not unhealthy. The general peritoneum was softer and more opaque than natural, and the other organs fairly healthy. Probably it would have been better in this case to have allowed the deep sutures to remain longer. And the case was one in which, as matters turned out, the drainage of Douglas's pouch at the time of the operation, on Dr. Marion Sims's plan, would have been attended with advantage.

CASE IX. Ovarian Cystic Tumour, chiefly composed of one Cyst: Ovariectomy: Recovery (Reported by Mr. W. MURRELL).—The patient, E. R., aged 34, was single. She had been a patient of Mr. E. E. Sass. The abdomen had been enlarged for two years. On admission, October 14th, 1873, there was found to be a rounded elastic fluctuating tumour, extending two inches above the umbilicus, on the surface of which were some nodules, one of which was half the size of a pigeon's egg. The vaginal examination showed the uterus to be retroverted, and the abdominal tumour was felt in front of it. The general condition of the patient was feeble. The diagnosis was apparently clear. The patient was suitably prepared for the operation by rest and feeding.

On December 14th, 1873, ovariectomy was performed in presence of Dr. Ensor, Dr. M. Jones, and others; Mr. Rigden giving chloroform, and Dr. John Williams, Mr. Murrell, and Mr. Barlow assisting. A short incision (three inches and a half) only was required. The cyst was found free from adhesions anteriorly, but the omentum was firmly adherent behind. The tumour was composed of one large cyst, with dirty cream-coloured fluid, and a few small secondary cysts; the latter were felt before the operation, anteriorly. The adhesions to the omentum bled freely on being torn through, and four small ligatures were required to check the hemorrhage. The pedicle, rather broad, was transfixed, tied in two divisions, and secured externally, its length admitting of this method of treatment, to Dr. Graily Hewitt's gutta-percha frame-clamp. The ends of the omental ligatures were also brought to the edge of the wound. Two silk sutures were applied deeply, others superficially. The patient fainted twice during the operation. The progress of the case after operation was satisfactory. The temperature on the third day once reached 101 deg.; afterwards, it was normal, until the seventh day, when slight bronchitis occurred, and it rose to 101.4 deg., and on the eighth day to 102.2 deg. Subsequently, it became normal. The clamp came away on the thirteenth day. The deep sutures were removed on the ninth day. Recovery was complete.

CASE X. Multilocular Cystic Tumour of Ovary: Preliminary Operation of Tapping: Ovariectomy a Fortnight Later: Recovery (Reported by Mr. MARKHAM SKERRITT).—S. H., aged 54, had had two miscarriages, but no living child. She had general good health till last year. For about twelve months past, she had been weaker and thinner, and the abdomen had increased in size. Lately, there had been prolapsus of the uterus, and oedema of both legs. She had been under the care of Dr. John Williams. On May 21st, 1874, her condition was as follows. She was emaciated; there was considerable oedema of legs. She had an ulcer above the outer malleolus of the left leg, and varicose condition of the veins of the legs. The abdomen was greatly distended; it measured thirty-nine inches in circumference. Fluctuation was very evident; the flanks were clear on percussion; the resistance of the tumour was great, apparently from extreme tension; at the lower part of the abdomen, there was a more solid feel. The uterus was prolapsed. The patient was unable to lie down; sleep was difficult. It was considered advisable to perform tapping as a preliminary. This was done on June 6th, 1874, and fifteen pints of a greenish yellow fluid were removed, viscid in consistence, and puriform towards the last. It was neutral, of specific gravity 1025, almost solid on boiling; it contained a multitude of small rounded nucleated cells, with a few oval large cells with single nucleus, like epithelial cells; also debris. After the removal of the fluid, a solid mass could be felt below. The tapping gave great relief.

On June 20th, 1874, ovariectomy was performed in the presence of Dr. Snegireff of Moscow, Dr. Miller and Dr. Reeve of the United States, Dr. Mogk and Dr. Baum of Holland, and others. Dr. John Williams assisted, also Mr. Markham Skerritt and Mr. Gould. Mr. Meredith gave chloroform. The abdomen had rapidly filled again since the tapping. An incision five inches and a half long was made. The tumour was found to be almost universally adherent by slight adhesions. There were about six ounces of fluid in the peritoneal cavity. The tumour was found to be made up of several principal cysts, each nearly of the size of a fist, and many smaller. The cyst which had been tapped had only refilled a little. The tumour now removed was about the size of an adult head, and it completely and tightly filled the pelvis. It was necessary to incise it and break it up, in order to remove it. The pedicle was on the left side, very short and very vascular. It was tied firmly, and dropped. The lower edge of the wound

was purposely left open, and a piece of lint inserted. On completion of the operation, the pulse was weak, otherwise her condition was good.

Her progress was very satisfactory. The temperature never exceeded 99.2 deg., until the fifteenth day, when it rose once to 100 deg., in consequence apparently of excitement on seeing her husband for the first time. There was a little tendency to retching for the first two days. A slight escape of sanious fluid from the wound took place a few hours after the operation. She had a little diarrhoea on the eighth day. The deep sutures were all removed by the twelfth day. The wound was a little slow in healing. On July 19th, she was discharged, cured.

SELECTIONS FROM JOURNALS.

SURGERY.

CHLOROFORM NARCOSIS RESUSCITATED BY NÉLATON'S METHOD.—The following case is recorded by Dr. M. H. Jordan of Birmingham, Alabama. Miss —, aged 18, stout, of full habit, and seeming to be in perfect health, applied to Dr. Eubank, a dentist of that place, to extract a tooth. Chloroform, after some solicitation, was given by means of a napkin made cone-shaped and held over the mouth and nose. After four or five inhalations, some spasmodic movements of the face being observed, the napkin was removed, and the patient directed to open her mouth, which she did, when the tooth was extracted without pain. No indications of a return of consciousness were observed, and the pulse became excessively small and feeble, and, along with the breathing, soon ceased to be perceptible. The patient was quickly placed prone on a bed, and Dr. I. W. Sears and Dr. Jordan were sent for. Dr. Sears, finding the jaws tightly closed, forcibly opened them with the handle of a spoon, and pulled the tongue, which had fallen back upon the fauces, well forward. The young lady was apparently dead; there was complete relaxation of the entire muscular system; the lips, face, and hands were livid; breathing and pulsation had ceased. Having in mind the experience of Dr. Marion Sims in a case described before the British Medical Association, the medical men immediately inverted the patient's body, the head hanging down, while the feet were raised high in the air by Dr. Eubank, both legs resting over his right shoulder; Dr. Nabors supported the thorax; Dr. Sears kept the jaws open and managed the tongue; while Dr. Jordan made efforts at artificial respiration by alternately pressing on the thorax and abdomen. After waiting for about five minutes for some indications of returning vitality, they observed one feeble attempt at respiration, followed after a long and painful interval by another; the attempts gradually became fuller and more frequent, accompanied by a return of the pulse, until they concluded that it was safe to place her back in bed. As soon, however, as she was put in the horizontal position, the breathing again ceased and the pulse disappeared. She was again placed as before, and efforts at artificial respiration were briskly kept up. After a prolonged interval, a feeble spasmodic gasp was heard, and was followed after another protracted interval by a second, then a third, etc., until the breathing finally became natural and the pulse returned. The lady was laid on the bed a second time, but soon there followed a spasmodic twitching of the muscles over the entire body, with a decided inclination to fall into a heavy sleep. It being difficult to keep her awake by mild means, stimulating applications were made along the entire spine, and her feet were put into almost scalding water, which roused her sufficiently to make further treatment unnecessary. At the end of four hours, she was able to drive to her home.

THERAPEUTICS.

ACTION OF IODIDE OF POTASSIUM IN THE HUMAN ORGANISM.—Professor Binz of Bonn believes that iodide of potassium undergoes the following changes when taken internally. In a healthy stomach, a part is changed by the hydrochloric acid into hydriodic acid ($KI + HCl = KCl + HI$); another portion is acted on by the chloride of sodium, so that iodide of sodium is formed; and, if the dose be large enough, a part remains unaltered. All the three combinations quickly pass into the circulation. The hydriodic acid here meets with soda, and forms iodide of sodium; but the alkaline combinations of iodine are again acted on in the tissue by carbonic and other acids, and iodine is set free. This free iodine has the property of combining with certain albuminous bodies; and in this, Binz believes, lies the explanation of the therapeutic action of the preparations of iodine.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, APRIL 3RD, 1875.

THE PUBLIC HEALTH BILL. 1875.

THE new Public Health Bill consists of 11 parts, 54 subdivisions, and 333 clauses, besides schedules.

Part I is preliminary; it gives the title and limits the operation of the Act, while it divides it into parts and defines the various terms employed.

Part II is devoted to "Authorities for Execution of Act". It gives the constitution of districts and authorities, and repeals the provisions of the Public Health Act of 1872. Here the second schedule to the Bill is to be interposed, consisting of sixty sections, regulating the election of Local Boards, who are incorporated, as also Improvement Commissioners, by the seventh section. It would, however, appear that the 46th section of the sanitary Act is to be repealed, and that rural sanitary authorities are no longer to be a corporation. Why, it is difficult to understand; as in many important particulars they have all the powers and obligations attaching to an urban authority, with the same necessity for a common seal and power to hold lands. The date of election is fixed for April 15th in each year, except where a local board for a district is elected for the first time, and then the first election is to be held on the day specified in the order constituting the district. An urban authority is to be the local authority for exercising the powers of the Bakehouse Regulation Act, the Artisans' and Labourers' Dwellings Act, the Baths and Wash-houses Act, and the Labouring Classes Lodging-Houses Acts. A rural authority is only burdened with the first of these Acts. If this Bill were simply to consolidate, without altering, the present laws, there would be nothing to say; but, as it professes and actually attempts to amend, we repeat our protest against the continuance of unsuitable bodies to carry out the law, e.g., boards of guardians, and against unnecessary distinctions between the powers and duties of the two classes of authorities, which distinctions, we hold, should be entirely abolished.

Part III deals with sanitary provisions; and its first subdivision relates to sewerage and drainage. Here we find a great improvement, vesting the management of all existing and future sewers in the local authority, thus making a change for which we have long called. When we first read the Bill, we were misled by the head-note, which says, "Sewers vested in Urban Authority"; but, by the section, urban and sanitary authorities are treated equally.

By the 16th section, which is a reprint of the 45th section of the Public Health Act of 1848, powers are conferred for making sewers. No notice is taken of the difficulty pointed out by Mr. Baron Bramwell, in the case of *Cator v. Lewisham Board of Works* (34 L. J., Q. B. 82), of the omission of power to cross lands. The words are repeated, giving power to carry sewers "into, through, or under any lands"; the word "across" should be added, as in the case of a street. By Clause 22, power is given to owners and occupiers to communicate their drains with sewers. Is this intended to give power to manufactories or unwholesome trade premises to drain into sewers? Is it an obligation on a sewer-authority to provide sewers and drains adequate to take all refuse from malt-houses, etc.? These most important subjects are left undetermined by the Bill. The next subdivision, disposal of sewage, leaves the law unchanged, and will disappoint many local authorities,

who expect that, in some unexplained way, all difficulties as to the disposal of sewage are to be removed by Government. It is clear that no absolute provision can be made which shall be applicable in all cases; and each individual district must continue as heretofore to determine for itself the mode best suited to its own wants and position, whether chemical deposition, irrigation of land, or intermittent downward filtration. But, as to sewage-works without the district, there is grave cause for complaint that the provisions of the Local Government Act of 1861 are again to be re-enacted. By the 5th section of that Act, it is required that, in all cases, before commencing any work for sewage purposes without their district, three months' notice shall be given by a local authority; and all persons who think themselves in any way affected are to be at liberty to object to, and may stop, the works. This is, in every case, unqualified, and has led to great difficulties in the past, which are to be continued in the future. A local board may obtain a provisional order, and this may be confirmed by Parliament; yet, after going through this long, costly, and anxious process, another inquiry is to be held, which may be prolonged for months; and, after all this, a power is lodged in the Local Government Board to disallow the work. Surely the one crying necessary for obtaining a provisional order ought to be adequate to protect all interests supposed to be injuriously affected; and, as no money can be borrowed for permanent works without inquiry by the Local Government Board, this inquiry ought to be sufficient for all purposes. As the law now stands, instead of helping on a local board in its endeavour to promote sanitary improvement, every possible difficulty is thrown in its way. A rural district is made up of several parishes, and often of many drainage areas; a rural sanitary authority determines to drain one of these, and for that purpose must make an outfall in another drainage-area of the same rural district. To this, the inhabitants of the proposed area to be used for outfall are fixedly opposed. Is the parish thus to be invaded without or within the district? This, only one of the many difficulties arising from the heterogeneous constitution of rural districts, is left undetermined by the Bill. The 34th section is on the subject of privies and water-closets. It is not to be lawful to erect a new house without sufficient privy-accommodation, or to rebuild any house pulled down to or below the ground-floor. Here is a perpetuation of an absurdity. Ought not every house to be provided with a sufficient privy, earth-closet, or water-closet? The next section (both being copied from the 31st section of the Public Health Act of 1848) provides accordingly. Why is it necessary that there should be the written application of any person to a local authority before the surveyor can examine into a nuisance? Surely, if he discover it himself, it ought to be sufficient without the intervention of any other person. Would it not also be well to make the local board the persons to determine whether it is a case of emergency? The section is left in this respect as indeterminate as the 54th section of the Public Health Act of 1848. To revert to the 20th section, why does not the Bill, instead of leaving the matter permissive, require every authority to keep a map of the system of sewerage existing in its district, to be kept up to the date of the works as they are erected, and also a plan to be sent to the local authority whenever any alteration is made in the drains of any premises? In case of outbreak of disease in a district, these plans would be invaluable, in order to discover and trace out its cause and transmission. Scavenging and cleansing streets and houses is provided for by Clauses 41 to 45; and cleansing offensive ditches and collections of matter by Clauses 46 to 49, which leave the law unchanged.

The next division, that of water-supply, is a very important one, and materially changes the position of sanitary authorities in this respect. Up to the present time, a sanitary authority had no power to construct water-works or to enter into competition with an existing water-works company in a district, so long as such company was able and willing to supply water; and a water-works company was defined as any corporation, person, or company of persons supplying, or who may hereafter supply, water for their own profit. This definition of a water company is continued in the present Bill; but, except as will be

hereafter mentioned, the existence of such companies is ignored in the 51st section unless incorporated by Act of Parliament or provisional order; but by the 58th section any water company may sell their undertaking to a local authority. The working of these sections will, therefore, be to place all water companies without parliamentary authority or provisional order, and established under deed of settlement or under the Joint Stock Companies Acts, entirely at the mercy of the local authorities within whose districts they supply water. They have no power to take up roads to lay their pipes; may at any time be indicted for a nuisance on opening pavements to lay service-pipes; and now public funds may be used in competition with their private enterprise, unless, under duress, they choose to sell their undertaking to the local authority "on such terms as may be agreed on".

Another and the most important matter is the incorporation of the Water-works Clauses Acts. Up to this time, while the duty was cast on the local authority to supply water, only as to 2d. per week was there any provision as to recompense to the local authority, except when a water-works company is established within the district, when the charges of the water company could be enforced by the local authority. Now, by the Bill, all powers which would attach to a trading community are to be exercised by the local authority supplying water; and power is also given to any authority to supply water to an adjoining authority; but Section 56 is not sufficiently clear as to the mode to be adopted, and does not define the limits within which a local authority can claim to enforce such supply. There is one serious omission; the 57th section reverts to the old 2d. per week, and further provides that, if more is to be charged for supply to any house, then the Local Government Board is to determine, "under all the circumstances of the case", what is to be charged. Are we right in supposing that the meaning of this clause is—That the Local Government Board in London are to determine the "reasonable" charge for water to every house supplied by a local authority? If this be not the meaning, we fail to see any other. Why not at once enact that the local authority may charge not exceeding £5 per cent. *per annum* on the estimated rental, or such other sum as the local authority may determine. The 62nd, 63rd, and 64th sections refer to protection of water; the first re-enacts clauses in the Nuisances Removal Act, 1855, and the Public Health Act, 1848, as to fouling water by gas-manufactories, with one important alteration, that the penalties may be sued for by the local authority in default of proceedings by the person whose water is fouled. The provision of the Sewage Utilisation Act of 1865 for protecting water within the district of a local authority is proposed to be re-enacted. But we have now sufficient knowledge to embody in a clause the admirable provisions laid down by Dr. Letheby for the guidance of the Thames Commissioners. Such a clause limiting the pollution in water-courses, whether caused by the sewage treated by local authorities or manufacturers, would be the first step towards cleansing our rivers, would be an admirable guide, and would render uncertainty impossible, save most costly litigation, and do away with the necessity for the threatened measure for preventing pollution of rivers. As the matter now stands, all is left in hopeless confusion. It is true, it is said in words that pollution from sewage is to be prevented; but no standard of purity is adopted, and, as already pointed out, no means are indicated by which trade nuisances can be prevented. We must commence sanitary improvement, directed against manufacturers, by a comparatively humble protest if we wish to succeed; and any arbitrary ideal standard of purity is sure to be unsuccessful in practice.

The regulation of cellar-dwellings and lodging-houses occupies twenty sections—re-enactments of previous statutes. A cellar is deemed to be occupied as a dwelling if any person pass the night therein; this should be "habitually" pass the night. The local authority may compel a supply of water to a common lodging-house, where such a supply can be furnished at a "reasonable rate". What is a reasonable rate? and who is to determine its amount? The provisions of the Public Health Act, 1874, are continued to every sanitary authority, with the sanction of the Local Government Board, empower-

ing the authority to make bye-laws in its district for regulating lodging-houses other than common lodging-houses.

Nuisances are dealt with in sections 85 to 104, and power is given, in section 102, to a local authority, to proceed in another district, if necessary, to remedy a nuisance arising in that district, but manifesting itself in the district of the local authority. The proceedings are to be taken in the district in which the nuisance arises. This is a great improvement on the existing state of the law, and has long been urgently called for. The definition of nuisances is not enlarged to cover such cases as that of the Great Western Railway Company and Bishop (41 L. J. M. C. 120) where rain-water dropping through a bridge, causing annoyance to passengers, was held not to be a nuisance within the present definition. In the next subdivision, relating to offensive trades, power is given to a local authority, as in the case of nuisances, to proceed when effluvia are given off in an adjoining district, but felt or occasioning injury within their own district. Are these enactments sufficient to protect against vapour given off in various trades and processes, not strictly effluvia, yet highly injurious, because destructive to vegetation, e.g., from alkali, copper, and other works? The sections which deal with unsound meat, fish, milk, etc., represent the present state of the law as amended by the Public Health Act, 1874.

Infectious Diseases and Hospitals is the title of the next division, which extends over fourteen sections. They provide for disinfecting premises either at the cost of owners or of occupiers, or of the local authority; and provision is made, as in the various sanitary Acts, for means of disinfection, etc. A new clause provides for the recovery of costs of maintenance in hospital of patients who are not paupers. The next ten sections relate to prevention of epidemic diseases and provision of mortuaries, and at present call for no remark.

Part IV commences Local Government provisions, and deals first with highways and streets. As heretofore, rural authorities are not given any control over these, the whole of the enactments being confined to urban authorities. The power to make bye-laws with respect to buildings, etc., is still confined to buildings to be erected, and not already existing; and the only change is that bye-laws may be made with respect to the structure of buildings "for purposes of health", whatever that may mean. For the first time, lighting with gas is made a sanitary purpose; and all gas companies not incorporated by Act of Parliament, or authorised to supply gas under a provisional order under the Gas and Water Facilities Act, 1870, may be opposed by a local authority competing with a private undertaking by the use of funds raised by taxation. In fact, except for purposes of purchase, the existence of all gas companies established by deed or under the Joint Stock Companies' Act, is ignored; and further power is given to a local authority to obtain a provisional order from the Local Government Board, which is to be substituted for the Board of Trade, enabling them to establish gas works and supply gas. Moreover, the Watering and Lighting Act of William IV, where adopted, is to be superseded by this Act within the district of every urban authority.

Public pleasure-grounds, markets, and slaughter-houses, and the provision of a public hall and clock, are the subjects of sections 157 to 164 inclusive, while the clauses 165 and 166 incorporate certain clauses of the Town Police Clauses Acts, 1847, with respect to obstructions and nuisances in the streets, fires, places of public resort, hackney carriages, bathing, horses, etc. These in the original act comprise clauses 21 to 69 inclusive, and form a study in themselves.

Part V deals with General Provisions: 1. Contracts; 2. Purchase of Lands by agreement or compulsion under the Lands Clauses Consolidation Acts, to be put in force by provisional order; 3. Arbitration; 4. Regulations as to Bye-laws; 5. Officers and Conduct of Business of Local Authorities. All officers may be appointed at the will of the local authority, and are to be removable at their pleasure. There is no restriction as to the length of the appointment; but there is a gracious power accorded by the 184th section to the medical officer of health, to exercise any of the powers with which an inspector of nuisances is proposed to be invested by the Bill.

Part VI relates to Rating and Borrowing Powers and Audit of Accounts. The rates remain still in the complicated condition in which they were left by the Act of 1872, where exemptions are granted to the extent of three-fourths of the amount of a rate in the case of a district rate; but where a borough rate is levied for the same purposes, no exemption whatever is provided. This will continue to be a fertile source of complaint, especially with railway companies, who strive in every private Bill to extend the area of this exemption, and who not unjustly complain that mere accident rather than principle determines whether the exemption shall apply.

Legal proceedings are dealt with under Part VII, which contains provisions as to prosecution of offences, and recovery of penalties. By the 245th section, all proceedings for penalties must be taken within three months from the time when the matter of the complaint or information arose. Regulations as to notices and appeals finish this part of the Bill.

Part VIII deals with Alteration of Areas and Union of Districts. Under Clause 267, regulations are made for continuing the powers of a superseded authority until the day of the first meeting of the new local board, and power is also given to the Local Government Board by order to provide for the settlement of any differences between districts, etc. Section 278 confers power on the Local Government Board to unite districts for the purpose of appointing one medical officer of health for the united district, and allows them to regulate his appointment and dismissal, and also to arrange the remuneration to be paid to such officer. But this power is limited in boroughs having a separate Court of Quarter Sessions; and, where any authority objects to be included in the united district, the order is to be of no force until confirmed by Parliament. There is also a very important power lodged in the Local Government Board—that of assigning to the medical officers of unions in any constituent district duties which they are to perform in rendering local assistance to the medical officers of health. For these services, the district medical officers are to be paid “such additional remuneration as the local authority may, with the approval of the Local Government Board, determine”. The last portion of this part of the Bill refers to port sanitary authorities.

The powers of the Local Government Board are fixed by Part IX, running over Sections 285 to 296. The famous forty-ninth section is strengthened by giving the Board power to apply for a writ of *mandamus*, as in the Public Health Act of last session. We wait with some curiosity to see whether this patched-up section, hitherto so useless and inoperative, will now be of any avail against apathetic and defaulting local authorities.

Part X is made up of miscellaneous and temporary provisions. It enacts, *inter alia*, that when a local Board or improvement district becomes constituted or included in a borough, then all the powers, etc., vested in such bodies, shall be, after the first meeting of the council of such borough, transferred to and exercised by the council of such borough; and it also confers power on a local board to change its name.

The eleventh and last part of the Act consists of saving clauses and repeal of various Acts; and this, with the various schedules laying down rules as to meetings and proceedings, rules for election of local boards, proceedings in case of lapse of local boards, and rules as to resolutions of owners and ratepayers, with various forms and repeal of statutes, complete this important measure.

It is but right to say that a more careful perusal of the details of the Bill has considerably modified our opinions as to its value; and, however open it may be to criticism, it appears to us much more skillfully drawn and more complete than we were at first disposed to believe.

DR. HITZIG of Berlin has been appointed Professor of Psychiatry, and Director of the Lunatic Asylum at Burghölzli near Zürich.

WE are glad to learn that Mr. Husband is going on favourably, but will have to give up work for a time, in order to prevent any after ill effect of the injury.

DR. H. DOBELL has been appointed Consulting Physician to the Hospital for Diseases of the Chest, City Road, after sixteen years' service as Physician.

MR. SPENCER WELLS has been unanimously elected an Honorary Fellow of the University of Charkoff. We are indebted to Professor Lazarewitch for this information.

By the will of Mr. James Young, late of Bournemouth, the testator leaves, amongst other legacies, the sum of £100 to John Stenhouse, M.D., F.R.S., to show his appreciation of his services to the country by the great discovery of charcoal as an air-filterer.

DR. WM. ARTHUR BRAILEY, M.A. Cantab., Curator, etc., to the Royal London Ophthalmic Hospital, and Fellow of Downing College, Cambridge, has been appointed Lecturer on Comparative Anatomy at St. George's Hospital Medical School.

It is reported that the Prussian Government has been petitioned to legalise cremation, but has refused, professing itself constitutionally incompetent to grant the permission. A special law passed by the Legislature would be requisite to effect the object.

It is reported that the Italian Government, following the course it has already adopted on previous occasions, will gratuitously distribute this year five thousand plants of the *Eucalyptus globulus*, for cultivation in the Agro Romano, especially in the spot infected by malaria. The plants will be allotted to all who apply for them, and who give assurances that they are to be used for the purpose stipulated.

THE WATER-SUPPLY OF LONDON.

A BILL bearing the names of Colonel Beresford, Sir Charles Russell, Mr. Forsyth, and Mr. Ritchie, has for its object the “making more effectual provision for a constant supply of water, and for the protection of life and property against fire in the metropolis”. It proposes to transfer the several undertakings of the eight companies now supplying water to the metropolis to a public commission to be constituted by an Order in Council, and entitled the Metropolitan Water Commission, and which shall have power to combine, as far as physical conditions admit, the sources of supply and works of the several companies; to dispose of works, lands, and property becoming superfluous in consequence of such combination; to continue any supply given by a company at the time of the transfer, and to extend from time to time their supply within the parishes supplied; to put the works into a condition for maintenance of constant supply at high pressure; to provide and place hydrants and apparatus for high-pressure supply in case of fire, and for other purposes; and to provide and fix apparatus for cleansing and watering streets, and for other sanitary purposes. The Commission is to have borrowing powers; and the Public Works Commissioners are to be empowered to lend money to the Commission on the security of their income. The shareholders of the existing companies are to receive perpetual annuities in consideration for the transfer of their shares.

BIRMINGHAM MEDICAL INSTITUTE.

At the first annual meeting of the members, the whole question of the admission of homœopathic practitioners was reopened and fully discussed. Mr. Alfred Baker, Mr. Clarkson, and Dr. Heslop supported the affirmative; Mr. Pemberton led the opposition. The result was a vote of sixty-four in favour of their admission, to thirty-five against it.

PUERPERAL FEVER.

THE trial of Elizabeth Marsden for manslaughter, in having conveyed the contagion of puerperal fever to a patient whom she was attending, and who afterwards died in consequence, took place on March 20th, at Manchester. She was found guilty, and sentenced to six months' imprisonment. In this case, the accused had not the plea of ignorance

to urge in extenuation of her criminal negligence, as she had been repeatedly warned by a surgeon on the danger she was incurring to others. As three deaths from puerperal fever were traced to the ministrations of this nurse, few people will be disposed to think that the sentence has been in excess of the offence.

TESTIMONIAL TO DR. A. P. STEWART.

It is with much pleasure that we publish in another column a report of a meeting of the Executive Committee of the Stewart Testimonial Fund on Wednesday last. It must be most gratifying to Dr. Stewart, as it is to us, that the mere mention of a proposed recognition of his labours in the interests of our great brotherhood has called forth a most hearty response from the members of the profession, and also from some who, though not members of our calling, have availed themselves of this opportunity of showing their esteem for an honest worker for the common good. It will not surprise those of our readers who know Dr. Stewart, to learn that he will consent to accept for himself only a small memento of the good-will of his brethren out of the amount which has been subscribed. With the greater part of the Testimonial Fund, he desires to found a grant "to encourage researches into the origin, spread, and prevention of epidemic disease, or such cognate subjects as the Committee of Council of the British Medical Association may from time to time, after due deliberation, determine". The idea of such an encouragement to good work does honour to the originator. The subject is happily selected. [It is worthy of note, that Dr. Stewart's scheme is not to reward competitive essays on prescribed subjects, but it is expressly provided that the grant shall be given for "important work done with a view to the continuance of like researches by the same person; and, when the Committee of Council shall think fit, to assist investigations by exceptionally qualified persons of questions likely to lead to important results".] Our knowledge does not at present carry us beyond the threshold of the important questions connected with the causation and prevention of epidemic diseases; and it is not unfitting that Dr. Stewart's name should be attached to a grant to encourage studies in which he himself has worked with success. To him we owe the important addition to our knowledge, that typhus and typhoid fevers are distinct diseases. His paper read before the Paris Medical Society in 1840 proved this, and may be said to have inaugurated a new era in the study of fever in this country. In conclusion, we call attention to the announcement that the list of subscriptions will be closed on April 30th. Any who are desirous of adding their names to the testimonial to Dr. Stewart are requested to communicate, on or before that date, with the Treasurer, Dr. F. Sibson, 59, Brook Street; or the Honorary Secretaries, Dr. J. Ford Anderson, 28, Buckland Crescent, Belsize Park, N.W., and Mr. W. Fairlie Clarke, 12, Mansfield Street, Cavendish Square, W.

LIVERPOOL HOSPITAL SUNDAY.

At Liverpool, the Hospital Sunday and the Hospital Saturday are happily under one management. The collections were made this year on January 10th, and January 16th, respectively. At the Sunday collection £7,475 16s. 11d. was obtained; while at the Saturday collection the amount raised was £2,148 19s. 0½d. The sum of £9,300 was distributed among the different hospitals and dispensaries.

VACCINATION PROSECUTION.

THE *Salisbury and Winchester Journal* contains the report of the conviction of Mr. Adam Wilkinson, medical officer and public vaccinator of the Shaftesbury Union, for not having his child, born March 12, 1874, vaccinated within the time specified by the Act of Parliament. The vaccination officer swore that he had served several notices, and called at the house. The child is a year old. The defendant was fined ten shillings, and ordered to have the child vaccinated within one month.

THE CENTENARY OF VACCINATION.

DR. BURGGRAEVE, Emeritus Professor in the University of Ghent, and principal surgeon of the civil hospital of that city, has prepared, in com-

memoration of the first centenary of the invention of vaccination, a work entitled *Histoire Générale de la Vaccine; ou, Monument à Edward Jenner, à l'occasion du premier centenaire de son invention*. The work will shortly be published in Paris by subscription: it is under the patronage of the King of the Belgians, the Emperors of Russia and Austria, the Kings of Sweden, Holland and Italy, and the Emperor of Brazil. The price of the work to subscribers is twenty-five shillings. The subscription list will be closed on May 30th, after which the price will be thirty-five shillings.

A NEW ARTICLE OF DIET.

A REPORT has been made by the Acting Political Superintendent at Akalkoit to the Government of Bombay, stating that there exists in those parts a weed called "mulmunda", the seed of which is used for food by the poorer classes in times of scarcity. The seed is ground into flour, of which bread is made. The bread is said to be sweet in taste, and, although not quite so satisfying as could be desired, does very well to keep body and soul together at a pinch. It is also given to camels for forage. The result of an examination of the plant, which is of a leguminous description, by the Acting Chemical Analyser to the Government, shows that the seeds contain nearly as much nitrogenous substances as some of the chief varieties of Indian peas and beans; and hence the nutritive value of the seed should be taken as equivalent to any of the other leguminous grains. The weed is said to grow all over the Deccan and Southern Mahratta country.

DRUNKENNESS IN GERMANY.

DR. SHATTUCK of Boston writes from Vienna:—Two cases which I saw in Fräntzel's service were so interesting to me, that I cannot forbear giving them a few words. A comatose man was brought into the hospital one Sunday afternoon by the police, who had found him in a freight car on a siding of one of the railways. His temperature was taken both in the axilla and in the rectum, at least two thermometers being used, and found to be 24.4 deg. C. (76 deg. Fahr.) Twelve hours later, it had come up to 33 deg. C. (91 deg. Fahr.); and not very long afterwards the man came to his senses, and said that Saturday afternoon he was on a spree, and was conscious of having drunk *three champagne bottles full of brandy*. He must then have wandered about till he laid himself down in the empty freight-car in which he was found twenty-four hours later. He recovered entirely. The other case was similar. A man was discovered by the police in one of the public gardens, unconscious. His temperature on entrance was 24.2 deg. C. (75.5 deg. Fahr.); and twelve hours later, when I saw him, he was still unconscious, with a temperature of 26.2 deg. C. (79.2 deg. Fahr.) The reaction being so slight, a bad prognosis was made for him; but I left Berlin too soon to hear the result. That he also had had a large dose of alcohol, is highly probable; but the fact could not be definitely ascertained. Fräntzel says that schnapps-drinking increases every year among the lower classes, and that every day-labourer who enters the hospital can be set down as a *potator* without hesitation.

THE DEVONSHIRE HOSPITAL, BUXTON.

WE have received a copy of the Report of the Devonshire Hospital and Buxton Bath Charity for 1874, and there are some features about it which call for notice. The title-page tells us that it was instituted for the relief of poor persons from all parts of Great Britain and Ireland suffering from—and then follows a list of about twenty ailments, concluding with "dyspeptic complaints, uterine obstructions, etc." This is the sort of thing that we are accustomed to in the advertisements of quack pills and potions, but is scarcely suited to the dignity of a first-class hospital. If it cannot be left to the patient's medical adviser to say whether Buxton would benefit him, this information might at least be put in a less conspicuous place. A list is given of the residences of the patients admitted during the year; and it appears that they come from all parts of England, as well as from Scotland and Ireland. We are glad to see that each patient is required to bring a letter of recommendation from some lady or gentleman resident in their neighbour-

hood, certifying whether he or she is a proper object with respect to circumstances. Knowing, however, as we do, how easily such letters are obtained, it would have been more satisfactory if, among the numerous tables, there had been one showing the social position—the occupations, trades, etc.—of the persons admitted to the benefits of the charity. We are under the impression that hospitals such as this are particularly liable to be abused. As the patients come from long distances, it is more difficult than usual to exercise a check upon them; and yet it is evidently desirable that great caution should be used in this respect, because we are told that the duties of the medical staff become more onerous every year, and because it is said that the institution could never offer them any adequate pecuniary remuneration for their services. Medical men have always shown their willingness to attend gratuitously the really poor of their own neighbourhoods; but, when patients are able to find the means of undertaking long railway journeys, there ought to be clear proof given that they are proper recipients of charity. The report is in all respects highly laudatory of Buxton and its hospital, and will afford most satisfactory reading for the visitors at the hotels and lodging-houses on a rainy day. The account of the meteorology of the district reminds us of the genial climates of the South; while the curative effect of the Buxton waters has been all that the most sanguine practitioners could desire: “more than seven-tenths of the patients are shown to have derived lasting benefit”. The report differs from most similar pamphlets by being drawn out to considerable length, and entering into many details, in order to set forth the attractions of Buxton. But the value of the Buxton waters is so well established, and the Devonshire Hospital stands so high, that a briefer and simpler statement of facts would certainly have had more weight with the profession, and probably also with the public.

SANITARY STATE OF CLIFTON, BARTON-ON-IRWELL.

A REPORT has been made by the medical officer of health on the sanitary state of the township of Clifton, in the Barton-upon-Irwell Rura Sanitary District. The report states that most of the ashpits and privies are in a very bad state. Many of the privies have no doors, and some of the ashpits are only so in name. One of the privies was in such a state that the people using it in wet weather had to carry an umbrella with them to protect them from the rain. The wells from which the people obtain their drinking-water are also in close contiguity to the ashpits and privies, and in many instances fouled in consequence. Speaking of one particular part of the township—viz., Rake Lane—the report says the sewage is permitted to lie about, owing to an absence of drains, and soak into the earth. The report concludes with recommending that a good system of drainage, and a good supply of water, should be provided; that a proper construction of ashpits and privies, and the closing of many of the old cottages, should be insisted upon. The chairman is reported—when this matter was under consideration of the sanitary authority—to have borne testimony to the urgency of these matters being attended to; but, notwithstanding, the further consideration was postponed for a fortnight. It is consoling to learn that there is no fever in this apparently sadly neglected locality.

BODY-SNATCHING.

A REVIVAL of the old profession of body-snatching is reported to have occurred in Montreal, owing to the high price paid for “subjects”. Several attempts, some of them being successful, have been made to disinter bodies from the Roman Catholic cemetery of that town. The accounts given in the Canadian papers remind us of the doings in England less than a hundred years since.

EDUCATION OF MIDWIVES.

THE following letter from Dr. Aveling recently appeared in the *Times*.

The estimated number of women practising as midwives in England and Wales is between ten and twelve thousand. The estimated number of women in large manufacturing town and villages attended in their confinements by midwives is from 30 to 90 per cent. Scarcely any of these midwives have received either instruction, examination, or license to practise in midwifery. Any ignorant old woman may adopt the calling, and the result of this permission is a large amount of disease and misery, which no coroner is called upon to investigate. Being fully convinced of this fact, the medical profession has lately taken steps towards remedying this deplorable maladministration. Joint committees of the British Medical Association and the Obstetrical Society of London have devoted much time to the subject, and have agreed, as a basis of action, to the following proposals.

“Definition of a Midwife.”—A respectable woman, able to read, write, and calculate, understanding the management of natural labour and the ordinary care of the mother and child after labour, and capable of recognising any conditions requiring medical aid during the parturient and puerperal states.

“Instruction of Midwives.”—This might be done by utilising the present lying-in charities and unions. Theoretical instruction might also be given by qualified medical men, and practical instruction at the bedside, and preferably at the patients’ homes, since experience has shown that it is neither necessary nor desirable to congregate a large number of lying-in women under the same roof.

“Examination and Licensing of Midwives.”—This would be best accomplished by a licensing body especially formed for the purpose; and the General Medical Council should be required and empowered by Act of Parliament to appoint this body.

“Registration of Midwives.”—It is believed that nothing short of compulsory registration of midwives will afford safe attendance during labour to those who are unable to distinguish between a good and a bad midwife. In future, every woman undertaking the duties of a midwife in England and Wales should be required to pass an examination prior to registration as such; and no public appointment should hereafter be given to any midwife who is not so registered. It is also thought desirable that all midwives at present in practice should, on the production of satisfactory evidence of fitness for the calling, be eligible to be placed on the register of midwives.

“Removal of Midwives’ Names from Register.”—Seeing that great injury might accrue to the public from midwives thus registered neglecting or exceeding their duties, it is considered necessary that provision should be made for the erasure from the register of the name of any midwife who has gravely misconducted herself.

These proposals were submitted to the President of the Local Government Board in 1873, and were so far approved by him as to elicit a promise to have a letter to the Privy Council drawn up recommending that some action for the amelioration of the present condition of our midwives should be taken. Owing to the change of Government, all attempts to bring the subject before Parliament have been temporarily abandoned. It is evident, however, that legislative interference cannot long be delayed, for the position of this country with regard to the instruction of midwives and the regulation of their practice, is when compared with the rest of Europe, disgraceful and humiliating. On the plea of public safety, it has always been considered right and necessary that Government should exercise control over all those who have under their charge the lives of the people it is bound to protect. An ignorant captain may not take command of a ship lest she should be wrecked and her crew and passengers drowned. No man may call himself a physician or a surgeon until he has proved himself competent to practise as such; and no one is permitted to open a chemist’s shop without having previously shown himself possessed of sufficient knowledge. Why, then, should the midwife, upon whose skill two lives may depend, be exempt from this beneficent rule?

FEMALE DOCTORS.

ON Monday, March 22nd, the first meeting of the Governors of the London School of Medicine for Women was held on the school premises, 30, Henrietta Street, Brunswick Square; Lord Aberdare in the chair. The Dean gave a short history of the school. He stated that during the winter session the same courses of lectures and demonstrations had been given as in the other medical schools of the metropolis, and that the number of women students attending was twenty. It was resolved that the proposed constitution and laws should be referred to a committee for consideration, and that in the meantime the school business should be conducted by the Provisional Council as heretofore. It was agreed that the next meeting of the governors should be held on

May 3rd, on which day the prizes will be distributed to those pupils who have been successful in the class-examinations.

THE DANGER OF "A LITTLE KNOWLEDGE".

A STRIKING instance of the danger of taking medicine without proper medical advice has just occurred at Croydon. Mr. Carrick of Croydon, having suffered from gout, made, from a recipe given to him by a friend, the following draught: Three pennyworth of potass, two pennyworth of flowers of sulphur, and two grains of the best gunpowder. Carrick sent a child out to different places for each ingredient; and for the potass the child went to an oil-shop, where, instead of iodide of potass (which was intended), common caustic potash was given. After taking a wineglass of the mixture, Carrick exhibited all the symptoms of irritant poisoning, and was removed to the Croydon General Hospital, where he died, after a fortnight's suffering, from inflammation of the bowels caused by the caustic alkali.

THE FACTORY ACTS.

A ROYAL Commission has been appointed for the purpose of inquiring into "the working of the Factory and Workshops Acts, with a view to their consolidation and amendment, and especially to consider whether they can be made more consistent and harmonious, and whether any of their provisions may properly be extended to other trades, industries, and occupations not included therein; and whether in the case of trades, industries, and occupations other than those dealt with by the Act of 1874, any further provisions are requisite for the improvement of the health and education of young persons and children".

THE WEATHER AND THE DEATH-RATE.

IN connection with a paper on the effects of great changes of the weather on the death-rate, by Dr. Arthur Mitchell, an abstract of which was published in the JOURNAL a few weeks ago, we note the following remarkable confirmation of Dr. Mitchell's remarks that the mortality of children is highest in hot weather, in the Melbourne *Argus*. "The mortality in Melbourne during the hot weather of the last week in January was very great. The number of burials in the Melbourne cemetery during the week were 270, of whom 106 were children. Among the adults there were no special causes of death, but the heat told terribly upon all children who were ailing. So soon as the cold weather set in, there was a great decrease in the number of deaths. The weather during that week was the hottest yet recorded in the colony; the thermometer at Melbourne ranging in the shade from 106 deg. to 111 deg., and in the sun from 140 deg. to 148 deg. Fah. Deaths from sunstroke were numerous."

INFECTIOUS OR CONTAGIOUS DISEASES.

THE Council of the Society of Medical Officers of Health have drawn up and are circulating a set of instructions for preventing the spread of infectious or contagious diseases. The rules have been drawn up with great care, and are not only exhaustive in detail, but have the great merit of brevity. Following the instructions is a list of penalties for negligence under the sanitary laws.

THE LATE DR. JOHN WATTS.

A MEMORIAL window of stained glass has been placed in St. George's Church, Shrewsbury, in memory of Dr. Watts, who was for many years a resident and churchwarden of the parish. It represents the figure of St. Luke, life-size, on a pedestal, with the following inscription:—"To the glory of God, this window, in memory of John Watts, M.D., who departed this life July 24th, 1874, is placed by the parishioners."

SCOTLAND.

PATRONAGE OF THE UNIVERSITY OF EDINBURGH.

At the last meeting of the Edinburgh University Court, Mr. A. Rutherford Clark was appointed one of the curators of patronage of the Uni-

versity for three years, in succession to Lord Neaves, whose second term of office expired on the 26th February last.

PROPOSED ARBORETUM.

At a meeting of the Edinburgh Town Council last week, a question was asked as to what had been done regarding the proposed acquisition of ground near the Botanical Gardens, for the purpose of forming an arboretum. The Lord Provost, in reply, said that at present he was in communication with Sir W. Gibson Craig on the subject; but he was afraid the Council would have to purchase the ground, and that afterwards the Government would take it over and keep it up; he thought the ground ought to be preserved to the city in the manner proposed, and hoped the Council would support him in his endeavour to accomplish so desirable an object.

HEALTH OF EDINBURGH.

FROM the report of Dr. Littlejohn, the Medical Officer of Health for the city, for the past month, we find that the average mortality of the city has been at the rate of 24 per 1,000, as compared with 21 per 1,000 last year; the deaths in the New Town being at the rate of 22, and in the Old Town of 28 per 1,000. A large proportion of the mortality was due to the inclement weather, 155 out of the total of 426 deaths being attributable to diseases of the chest. There were only three deaths from typhus and typhoid fever, 30 from scarlatina, and 34 from whooping-cough.

UNIVERSITY OF ABERDEEN: MACKENZIE PRIZES.

THE Senatus of the University of Aberdeen has announced that all matriculated students of the present session may compete for the following prizes, offered by Mr. Mackenzie of Glenmuick:—Two prizes of £70 and £30 respectively for essays on Labour and Capital; £30 and £20 for essays on Ancient and Modern Systems of Colonisation; and £30 and £20 for essays on the Conservation of Energy, especially with reference to the mechanical theory of heat. The essays will be adjudicated on in November next.

THE RESIN OF ALOES.

At the fifth meeting of the Edinburgh Pharmaceutical Society, Dr. W. Craig read a communication on the resin of aloes, with special reference to its action and effects. In the course of the paper, he showed that the resin was not a purgative, and therefore could not be the active principle of the drug, the resin being not only weak as a laxative, but altogether a very harmless substance. Aloine, he held, might, by exposure to the air, undergo a considerable chemical change without losing its physiological action as an active aperient: it was probably the active principle of the drug.

DISCOVERY OF HUMAN REMAINS.

AN interesting discovery of human remains was lately made near Laureekirk. While some farm-servants were removing gravel from a pit on a neighbouring hill, they found near the surface an oval vessel eleven inches by eight inches, apparently of clay, and containing parts of the skull and other bones of an adult, very much decayed. They are supposed to be those of Sheriff Melville, who, in the year 1430, was boiled alive near this spot by five savage highland lairds, with whom he had been at enmity.

VIVISECTION.

ON the motion of Professor Sir William Thomson, at a meeting of the Society for the Prevention of Cruelty to Animals, held in Glasgow recently, it was agreed to petition Parliament in favour of a Bill to enforce proper restriction on the practice of vivisection. Sir William Thomson said there was a tendency to have vivisection repeated unnecessarily. It was far from his intention to join in any movement which would unduly restrict men of science in whatever operations might be necessary for advancing knowledge, but he considered that

the repetition of cruel experiments on the lower animals, merely for the purpose of showing students what had been done, was altogether unnecessary. Professor Nichol, who seconded the motion, said that, when it was necessary to resort to that practice, precaution should be taken to reduce the pain to a minimum, and that, when the experiment was over, the animals should be put to death.

IRELAND.

ADULTERATION OF FOOD IN DUBLIN.

IN Dublin, during the past year, there have been condemned 192,210 pounds of beef, 10,600 of mutton and veal, with a large quantity of pork, as being unfit for food. During the year, 385 sorts of food were analysed, and 220 were found to be adulterated: whilst, of twenty specimens of water, fourteen were found to be tainted with sewage. The adulterators numbered 147, and the fines indicted amounted to upwards of £150; one party being imprisoned for three months, three for two months, and one for six weeks. Within the past year, it may be stated, 1,690,000 pounds of unsound food have been confiscated in Dublin, the fines coming to £1,200.

LEDWICH SCHOOL OF MEDICINE: CHAIR OF CHEMISTRY.

AT a meeting of the Board of Proprietors of this Medical School held on March 29th, the appointment of a Lecturer on Chemistry, vacant by the retirement of Dr. Cameron, was filled up. There were three candidates, Dr. Handzel Griffiths (Librarian to the College of Surgeons), Mr. Tichborne, and Mr. Lapper. The first named gentleman was selected, subject to the regulations of the school.

HEALTH OF IRELAND: QUARTERLY REPORT.

THE returns for the last quarter in the past year show that the births registered amounted to 32,429, and the deaths to 22,705, the latter exceeding by 1,147 those registered in the corresponding quarter of the previous year. This increased mortality was mainly due to the prevalence and fatality of scarlet fever, a disease which destroyed not less than 1,427 persons. The steady increase of this disease from the commencement of 1874 is shown by the fact that, during the first quarter, this affection killed 760 persons; in the second quarter, 731; in the third, 976; and in the fourth, 1,427; making a total of 3,894 victims to this plague, as occurring in the year. Diphtheria caused 173 deaths; whooping-cough proved fatal in 376 instances; fever was the cause of 634 deaths; small-pox numbered 148, which large number was owing to the practice of inoculation which exists extensively in several districts, especially in the Kiltamagh district of the Swineford Union, and in the Balla district, Castlebar; in the latter, out of 40 deaths registered, no fewer than 23 resulted from small-pox, the registrar stating that inoculation has been carried out to "a fearful extent" in his district.

MILK ADULTERATION AND THE ADULTERATION BILL.

AT a recent weekly meeting of the Society of Arts, Mr. WANKLYN read a paper on milk adulteration, and the proceedings gave rise to an interesting discussion on the Adulteration Bill, and on analysts and analyses. Mr. P. LE NEVE FOSTER presided.

Mr. WANKLYN said that, in selecting milk for the purpose of illustrating the need for an Adulteration Act, and of exemplifying the working of the Act, he had been influenced by a variety of considerations. In the first place, milk-analysis had been much developed of late years, and was now better shown and more certain in its indications than almost any other branch of the analysis of food. In the second place, the adulteration of milk was very largely practised, and was likely to be much diminished, if not altogether abolished, by the action of the Act. The constancy observable in milk, regarded from one point of view, and variety in richness, afforded examples of different methods of treatment, and rendered the subject of milk a good typical example of what might be done under the Adulteration Act. He went on to explain practically the process of milk-analysis, saying that it was

very easy to understand, and described the average composition of cow's milk. He said—

"In 100 centimetres of milk, there are 5.65 *grammes* of 'solids not fat', and 3.16 *grammes* of fat. In order practically to ascertain how much solids exist in a given specimen of milk, a known quantity of milk (measured or weighed out) is exposed to a temperature of 212 deg. Fahr. for a length of time. At this temperature, the water of the milk evaporates, whilst the solid constituents remain unaltered. It is usual to employ about 5 cubic centimetres of milk for this purpose, and to put it in the water-bath for three hours, at the expiration of which period the water is found to have completely evaporated, and the residual solids may be weighed. One of the modern improvements has been the selection of a suitable quantity of milk for the purpose of taking the solid residue. Formerly far too much milk was used, and loss of time and impairment of accuracy were the consequence. When five cubic centimetres are exposed for three hours to a temperature of 282 deg. Fahr. (rigidly maintained for the whole period), the milk-residues may be obtained so constant in weight as not to vary by more than 0.02 *gramme* per 100 cubic centimetres of milk. This is a degree of accuracy which rivals that of the very best processes of chemical analysis. The next step is to expose the solid residue to the solvent action of ether, which dissolves the fat out of it, and leaves the 'solid not fat' behind. The ethereal solution of the fat may be afterwards evaporated at a gentle heat, and the fat which remains after the ether is gone may then be weighed. Thus, we have the weight of the total milk-solid and the weight of the fat yielded by 100 cubic centimetres of milk. If the latter be subtracted from the former, the weight of the 'solids not fat' will be arrived at. Generally speaking, the analysis is complete when this stage is reached; but, if anything further be needed, another portion of the milk may be burnt, and the residue weighed, by which means the quantity of ash or mineral matter in the milk is arrived at. The milk-sugar may also be obtained and weighed by submitting the 'solids not fat' to the solvent action of alcohol and water, which dissolves it, and leaves the caseine and major part of the mineral matter in an insoluble condition."

He proceeded to speak of the various adulterations practised by milkmen in regard to watering, and the lesser adulteration of mixing stale skimmed milk with new milk. In 1871 and the early part of 1872, he examined about 1,000 samples supplied to boys and girls as customers, and 90 per cent. of these showed results proving that the milk was below the normal mark, and was not genuine. The milk of the hospitals was examined with a like result. Of the thirty London workhouses, twenty-nine gave samples for examination; and of these nearly all were largely adulterated—in fact, one was nearly half water, in place of the "genuine, new, unskimmed milk to produce 10 per cent. of cream", as contracted for. The result of this was that the ratepayers were mulcted of a large portion of the £13,130 paid for workhouse milk, and the young and aged poor who had a milk-diet were wronged. He summed up his paper by stating that the general result of his investigations was that, before the year 1872, nine-tenths of the milk sold as new or whole milk was milk which had been either skimmed or watered to a very palpable extent. This state of matters called for legislative action, and accordingly the Adulteration Act was passed.

"On the present occasion, pending the passing of the new Adulteration Act, it may not be inappropriate to refer to the provisions of the Bill as present before Parliament. The leading features of the Bill, as likewise of the Act of 1872, are the enactment of heavy penalties for poisoning, and lighter penalties for the mere deterioration of provisions. On examining minutely, there are unmistakable signs that the Bill has been drawn up by persons very imperfectly informed of the nature of the subject matter dealt with by the Bill. How otherwise can we account for the placing of the poisoning of drugs on much the same footing as the poisoning of food? Some of the most valuable drugs are most powerful poisons—and what meaning, for instance, would be attached to the poisoning of morphia? Even the poisoning of food is not correctly dealt with by the Bill, which obviously proceeds on the false assumption that the addition of that which is poisonous *per se* is necessarily to render the article of food poisonous."

Mr. BRANSON expressed an opinion that prosecutions should not be undertaken on analyses, which he did not appear to estimate very highly. While condemning the present Act, he denounced the new Bill as a half-hearted measure. If the adulterators had paid the draftsman a fee, he could not have endeavoured to do more for them than in the proposals of this Bill.

Mr. HOLBORN said that Mr. Wanklyn himself had offered to make up fats which other analysts would declare to be pure butter. Analysts differed greatly. Was it not a mistake to give up our "forefathers' system" of judging articles of food, and to take to judging them as matters of pharmacy? He referred to the Liverpool cases of butter and tea,

saying that in the tea case the unlucky trader was fined for selling a pure article; and in the butter case four opinions had been given by as many analysts.

Mr. W. L. SCOTT had used the processes described by Mr. Wanklyn. Of 8,000 specimens of London milk which he had examined, 74 per cent. were adulterated. As to standards, he thought a hard and fast line could not be laid down, as cattle differed as to the milk they gave in different districts. He stated, too, that the analyst at Greenwich had found salt in milk, this being put in to raise the specific gravity.

Mr. BARTLETT, referring to Mr. Wanklyn's manual on *Milk Adulteration* in terms of commendation, questioned if the ether used for dissolving the fat did not take up the 10 per cent. of milk-sugar which the 10 per cent. of water taken up would dissolve. As to the "Liverpool butter case" mentioned by Mr. Holborn, he denied that it was a case in point; for when the butter came to him it was in a decomposed state, and he refused to touch it; Dr. Anderson of Glasgow, who attempted to do so, afterwards refused to give a certificate either way. He did not hold a public appointment, and, therefore, he could say something in defence of the public analysts against the attacks made upon them by Mr. Holborn. They only did their duty at the call of the local boards who initiated the prosecutions. In regard to milk adulteration, he said there was a sophistication which made milk worse than the addition of water; and that was its condition when it was stale, and contained a large amount of lactic acid, rendering it particularly unwholesome for children, and not good for anyone. Milk in this condition was adulterated with various alkaline substances to conceal the sourness, and in some cases these substances were put in to prevent acidity from occurring. Carbonate of soda and carbonate of potash had been used; and he had actually been consulted by persons in the milk-trade as to the use of boracic acid, borate of soda, and even of caustic potash. The analysis of ash in milk was an important point. He spoke on the Bill now before Parliament, and condemned it as crude and impracticable.

Mr. FLUX considered that Act had done good, but suggested that proceedings under it should not be taken in a criminal court.

The lecturer replied; and a vote of thanks to him and the Chairman concluded the proceedings.

TESTIMONIAL TO DR. A. P. STEWART.

A MEETING of the Executive Committee of the Testimonial to Dr. A. P. Stewart was held at Dr. Sibson's, 50, Brook Street, on Wednesday, March 31st, at which the subcommittee, appointed at a previous meeting to confer with Dr. Stewart as to the form the testimonial should take, presented their report. Dr. Stewart consents to allow a small part of the amount subscribed to be expended on a personal gift; but he desires that the bulk of the fund be applied in establishing a grant which shall be in the gift of the Committee of Council of the British Medical Association. It was agreed that this fund should be called the "Stewart Grant"; and the following scheme for its application, suggested by Dr. Stewart, was submitted to the meeting and approved.

1. The object of the Stewart Grant shall be to encourage researches into the origin, spread, and prevention of epidemic disease, or such cognate subjects as the Committee of Council of the British Medical Association may from time to time, after due deliberation, determine.

2. For this end, the funds shall be invested in the name of three trustees, to be appointed by the Committee of Council of the Association.

3. The accumulated interest shall be given biennially or less frequently: Firstly, and as a general rule, in recognition of important work already done by such person or persons as the Committee of Council of the British Medical Association, or a committee appointed by them for such purpose, shall deem most deserving, with a view to the continuance by such person or persons of like researches in the same direction; or, secondly, as an encouragement to such person or persons as the Committee of Council, or a committee by them appointed, shall consider exceptionally qualified to undertake the investigation of such question or questions as shall appear likely to lead to further important results.

It was further decided by the Executive Committee that the subscription list should not be closed till April 30th; and those who are desirous of adding their names may communicate up to that day with the treasurer of the fund, Dr. F. Sibson, F.R.S., 50, Brook Street, W.; or either of the honorary secretaries, Mr. W. Fairlie Clarke, 12, Mansfield Street, W., and Dr. J. Ford Anderson, 28, Buckland Crescent, Belsize Park, N.W.

DISCUSSION ON PUERPERAL FEVER.

At the meeting of the Obstetrical Society of London on April 7th, Mr. Spencer Wells will open a discussion on the Relation of Puerperal Fever to the Infective Diseases and Pyæmia. The attention of those who take part in the discussion is directed to the following questions.

1. Is there any form of continued fever, communicated by contagion or infection, and occurring in connection with childbirth, which is as distinctly caused by a special morbid poison, and as definite in its progress and the local lesions associated with it, as typhus or typhoid, scarlet fever, measles, or small-pox?

2. May all forms of puerperal fever be referred to attacks of some infective continued fever—as scarlet fever or measles—occurring in connection with childbirth, on the one hand; or, on the other, to some form of surgical fever, or to erysipelas, caused by or associated with the changes in the uterus and neighbouring parts following the process of childbirth?

3. If all cases of contagious and infectious diseases which occur under other conditions than that of childbirth are set aside, does there remain any such disease as puerperal fever?

4. Assuming that a form of continued fever—communicable by inoculation, contagion, or infection—does frequently occur in connection with childbirth, how can its spread in private and in hospital practice be most certainly prevented or checked?

5. What relation have bacteria and allied organic forms to the pyæmic process in the puerperal state?

6. What is the value of anti-septics in the prevention and curative treatment of puerperal fever?

The meeting will commence at eight o'clock. The necessary preliminary business will occupy but a short time. At its conclusion, Mr. Wells will commence his opening address, and will limit himself to fifteen minutes. It is expected that the speakers generally will not exceed this limit.

Dr. Braxton Hicks, Dr. Barnes, Mr. Jonathan Hutchinson, Dr. Hall Davis, Dr. William Squire, Dr. E. W. Richardson, and many other gentlemen, are expected to take part in the discussion; and at the second meeting, should the discussion be adjourned, it is hoped that Professors Lister of Edinburgh and Billroth of Vienna will be present, with Dr. Fordyce Barker of New York.

Mr. Wells will ask for a few minutes at the close of the discussion, in reply to the various speakers.

SPECIAL CORRESPONDENCE.

VIENNA.

[FROM AN OCCASIONAL CORRESPONDENT.]

The School.—Prevalent Diseases.—Bamberger's Use of Quinine.—Typhoid Fever.—Puerperal Fever.—Billroth on the Practice of Medicine by Women.—Zeissl on Syphilis.—The Weather.

THE winter session has lately closed, and the University classes are now discontinued. The number of students is smaller than in some previous years; but there have been about 1,100. Of this number, about forty were Americans, and ten British. It was amusing the other day at a special course to see a professor lecturing fluently in German to a class of ten, of whom no fewer than seven were English speaking.

Vienna retains its known eminence of mortality from pulmonary consumption. The habit of living in overheated, foul-air, crowded rooms can hardly fail to favour tendencies to tubercular formations. Croup has been very rife and very fatal among children. Of ten cases in which tracheotomy has been performed in the Children's Hospital within the last two months, all have proved fatal; and the *post mortem* examinations have shown that in all the croupous exudations had extended down into bronchi not larger than a knitting-needle. The tendency to pulmonary extension becomes a characteristic of the epidemic. The chief treatment pursued has been inhalations of lactic acid and lime-water.

Professor Bamberger, successor to Oppolzer, has been using quinine pretty widely as an antipyretic or dephlogistic. He has found single doses of fifteen grains to reduce very markedly the temperature in pneumonia; and the diminution continues for forty-eight hours; a return of pyrexia is checked by a second smaller dose of quinine. In cases where it is not contraindicated by age or feebleness, Bamberger now combines with quinine the use of the wet sheet, and with excellent result. Except nourishment and palliation of any troublesome symptom, no other treatment is pursued.

Typhoid fever, or "typhus entericus", furnishes a large number of cases in the medical wards, and appears to be constantly present in Vienna. This is only to be expected from the inefficient drainage of much of the old city, and the fact that much of the water-supply is from wells.

Puerperal fever carries off a number of patients; and it seems strange to find both Professor Carl Braun's and Professor Späth's assistants conducting classes of practical obstetrics on the dead body while daily examining and delivering parturient women in the wards.

Professor Billroth recently gave a lecture in which he strongly condemned the introduction of females into the ranks of the medical and surgical profession, and went so far as to say that women's mental powers were far inferior to men's on the average, and that the character of their minds unfitted them for the exercise of medicine.

In the wards of von Sigmund and Zeissl, syphilis in its earlier stages is invariably attacked by mercury; and the former has lately been using inunction of blue ointment extensively. Zeissl expressed himself forcibly on the subject of the eradicability of syphilis. "Some", he said, "think when a patient has for some time enjoyed immunity from manifestations of syphilis, that he is cured. But I tell you, gentlemen, that, if a man contract syphilis, he will die syphilitic, and at the Day of Judgment his ghost will have syphilis."

From the latter part of January till the 8th instant, we had an unbroken frost, and the thermometer has registered as low as -17° deg. R. (6.75 below zero, Fahr.) at nine o'clock in the morning in the city. After a few days' thaw, came fine bright spring weather; but one night lately there was again a slight fall of snow, and a recurrence of low temperature. Everyone speaks of this as an exceptionally severe winter, and the memories of the oldest inhabitants are ransacked for dates of comparison.

ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the office of the Association, 36, Great Queen Street, Lincoln's Inn Fields, London, on Thursday, the 15th day of April next, at two o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary*.

36, Great Queen Street, London, W.C., March 18th, 1875.

METROPOLITAN COUNTIES BRANCH.

A GENERAL Meeting of this Branch will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Friday, April 16th, at 8 P.M.; when a discussion will be opened by Mr. HOLTHOUSE on the subject of Legislation for Habitual Drunkards.

ALEXANDER HENRY, M.D. } *Hon.*
ROBERT FARQUHARSON, M.D. } *Secs.*

BIRMINGHAM AND MIDLAND COUNTIES BRANCH.

THE next meeting will be held in the Council Room of the Midland Institute, on Thursday, April 8th, 1875, at 3 o'clock P.M. precisely.

Business.—To receive a report from the Habitual Drunkards Committee. To nominate the Officers, Council, and Representatives of the Branch in the Council of the Association for the ensuing year.

The following papers are promised:

Observations on Congenital Cataract and its Treatment: Mr. J. Vose Solomon.

On General Paralysis of the Insane: Dr. Fowler Bodington.

Members are invited to exhibit pathological specimens at the commencement of the meeting.

BALTHAZAR FOSTER, M.D. } *Hon.*
JAMES SAWYER, M.D. } *Secs.*

BIRMINGHAM AND MIDLAND COUNTIES BRANCH: ORDINARY MEETING.

THE fifth ordinary meeting of the Session was held on February 11th, at the Midland Institute, Birmingham; present, W. C. GARMAN, Esq., President, in the Chair, and forty-four members and visitors.

Habitual Drunkards Committee.—The report of the Committee appointed to consider the subject of legislating for the care and restraint of habitual drunkards (which has already appeared in the JOURNAL) was read by the PRESIDENT as Chairman of the Committee. The report was adopted, and ordered to be printed and forwarded to the Secretaries of all the Branches of the Association.

Medical Education.—It was moved by Dr. FOWLER BODINGTON, and seconded by Mr. JOHN MANLEY—"That the amended report of the Education Committee, together with the scheme, be adopted by the Branch, and forwarded to the Editor of the JOURNAL for publication."

Mr. SAMPSON GAMGEE moved, and Mr. J. VOSE SOLOMON seconded, the following amendment—"That the amended report of the Education Committee be received and entered on the minutes; and that the warmest thanks of this Branch be and are hereby tendered to Dr. Fowler Bodington, the Chairman, Mr. A. Oakes, the Honorary Secretary, and the other members of the Education Committee, for the deep interest and unsparing exertions with which they have promoted and conducted the discussion on the important question of medical education."

The amendment was carried by a large majority, and was afterwards adopted as a substantive resolution.

Hour-Glass Contraction of Stomach, etc.—Dr. THOMPSON (Leamington) showed a specimen of hour-glass contraction of the stomach; a gall-bladder contracted to the size of a little finger containing several gall-stones; and specimens of fractures of ribs, old and recent, showing fragilitas ossium. They were all removed from the body of a female aged fifty-eight, who died suddenly under suspicious circumstances. She had suffered from asthma; and the immediate cause of death was pleurisy.

Functional Derangement of the Ovaries.—Dr. MALINS read a paper on this subject, pointing out the comparative frequency of such derangements, their influence on health, and their relation to uterine disease. The treatment of these perversions was also considered, stress being laid upon the harm arising from local uterine treatment where there is frequently only functional disorder of the ovaries, and attention drawn to the importance of early training and associated mental conditions.

Ovarian Tumour.—Mr. LAWSON TAIT showed an ovarian tumour which he had removed the day before, and which presented some features of interest. The patient had been sent to him from Stockton-on-Tees, and was of such great size that he deemed it advisable to adopt a practice against which he had a superstition, namely, preliminary tapping. He removed seven pints from the major cyst, but was disappointed to find that in two days the patient was as large as ever. From the absence of any symptoms, he hoped that this rapid increase was not hæmorrhagic; but, at the operation, he found that the cyst contained about three pints of blood-clot, yet the patient had no anæmic symptoms or appearance. On exposure, Mr. Tait found the tumour to be coured over by large venous sinuses, and the pedicle to be very short, and intimately related to the uterus. He enclosed it in large bull-dog forceps, and, on the separation of the tumour, it was found to be occupied by numerous venous sinuses of very large size. These were tied, and the stump dropped back. So far, the patient had had no bad symptoms.

Mechanism.—Mr. TAIT also showed the self-retaining convolvulus catheter, the calculus-detector, and the calculus-extractor of Mr. W. D. Napier, all of which he had used, and which he characterised as the perfection of ingenuity.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT MEETING.

THE fifty-fifth meeting was held at the Harp Hotel, Dover, on Thursday, March 18th, 1875, at three o'clock; FRANCIS E. BARTON, Esq., in the chair. Eighteen members and three visitors were present.

Intussusception of the Rectum.—Mr. OSBORN read an interesting report of a case of intussusception of the rectum in an adult female recently married. The case was attended with the usual symptoms, except that the sanguineous discharge was slight. Enemata and other remedies failed to reduce the intussuscepted bowel, though the obstruction was temporarily overcome by means of a stomach-pump tube passed through the strictured orifice. Fluid was introduced, and the softened feculent matter withdrawn by the instrument. The patient, however, became gradually exhausted, and died somewhat suddenly, after experiencing a rather severe pain at the lower part of the abdomen. A *post mortem* examination revealed an intussusception of about three-fourths of an inch of the rectum, having its serous surfaces strongly adherent; the mucous surfaces were pale, and showed no signs of sphacelus. Death appeared to have been due to exhaustion, though a minute rent, overlooked in the examination, may have been the cause.

Diphtheria and Croup in East Kent.—Dr. ROBINSON read notes on epidemics of diphtheria and so-called croup in East Kent during 1874. He considered that the term croup was frequently used to designate prominent symptoms rather than the complete pathology of the disease, and

consequently that cases of diphtheria were classified under the head of croup. Catarrhal laryngitis and laryngismus stridulus were not so likely to be confounded with diphtheria, as that form of laryngeal inflammation termed croup was characterised by plastic exudation and membraniform production. The morbid anatomy here could not be shown to differ from that of diphtheria. He laid great stress on the contagious character of diphtheria, and the persistent activity of the specific virus of the disease; and brought forward a mass of evidence occurring in his district to prove the excessive contagiousness of diphtheria, and the difficulty that many medical practitioners had evidently encountered in order to decide whether they should term the disease diphtheria or croup. Dr. West long ago regarded diphtheria as a variety of croup; and Squire, in Reynolds's *System of Medicine*, said, "epidemic croup is strictly diphtheria"; but these authors did not speak of diphtheria as a communicable disease and requiring precautionary measures against its spread. Sir Thomas Watson said, "croup is not contagious". Now, if croup and diphtheria were identical, the sooner that was generally admitted the better, because the designation of a decidedly contagious disease like diphtheria by a term used to imply a non-contagious malady was fraught with great danger to the public, and calculated to retard the acquisition of further knowledge on the subject. The paper provoked an animated discussion, and the great difficulty met with in deciding whether a case was one of diphtheria or of croup was universally acknowledged.

Paracentesis Abdominis.—Mr. MARSHALL read a short paper on paracentesis abdominis, with the advantage to be derived from using a small trocar and cannula. He stated that his method offered the following advantages. 1. No incision being necessary, less pain was inflicted. 2. Syncope was less likely to occur, the evacuation of the fluid being more gradual. 3. The wound closing immediately, no oozing of fluid occurred. 4. Great relief was experienced on the removal of seven or eight pints in this manner. 5. The operation was unattended with danger, either at the time or subsequently. The author brought forward cases exemplifying the above advantages.

Esmarch's Method.—Mr. THURSTON narrated a case of amputation of the thigh with Esmarch's plan, and spoke highly of the use of the elastic bandage, especially in sudden emergencies occurring in a country practice, lessening as it does the necessary number of assistants, or giving time for seeking further aid. He laid great stress on the necessity for regulating the amount of force applied by the elastic tubing, according to the amount of resistance the tissues are likely to give.

Dinner.—Twenty members and their friends afterwards dined together, under the presidency of Mr. Barton.

Next Meeting.—The next and annual meeting will be held at Canterbury on May 20th.

WEST SOMERSET BRANCH: SPRING MEETING.

THE spring meeting of this Branch was held at the Royal Clarence Hotel, Bridgwater, on Thursday, March 18th, at 5.15 P.M.; H. W. RANDOLPH, Esq., President, in the Chair.

After dinner, the Secretary laid before the meeting letters of regret from several members who were prevented from attending by sickness and other causes. The minutes of the last general meeting were read and confirmed.

Causation of Typhoid Fever.—Dr. ALFORD (Taunton) read a paper on this subject. A discussion followed; and Dr. Alford having suggested that members of the Branch should record facts as to the origin and attendant circumstances of cases of typhoid fever which might occur in their practice, and offered for use a tabular form which he had prepared for the purpose, it was resolved, "That the thanks of this meeting be tendered to Dr. Alford for his paper, and that the form of table he has laid before the meeting be adopted for use in recording facts relative to cases of typhoid fever; that the Secretary be requested to have the form printed, and a copy supplied to each member of the Branch. The form when filled up to be returned to the Secretary."

Treatment of Habitual Drunkards.—The question of the best mode of treatment of habitual drunkards was introduced by the PRESIDENT. He adverted to the efforts made by the late Mr. Dalrymple to get an Act of Parliament passed for putting habitual drunkards under restraint, and expressed his own views in accordance therewith. He proposed that the Branch should petition Parliament to take the subject into consideration with a view to supplying some legal remedy.

The Secretary read written answers from Dr. Conlwent (Taunton), Dr. Clark (Dunster), and Mr. Stephens (Ilminster). After a lengthened discussion, the following resolution was passed:—"That this meeting is of opinion that the legislature should be petitioned to enact some measure for dealing with habitual drunkards and placing them

under proper restraint; and that the President be empowered to sign a petition on behalf of this Branch, provided such petition be not opposed to the views enunciated at the meeting this evening."

The above resolution was framed in the belief that a form of petition for general adoption by the Branches of the Association will be recommended by the Council of the Association.

SOUTH-WESTERN BRANCH: TESTIMONIAL TO DR. RUMSEY.

I BEG to inform the members of this Branch that, at the suggestion of our President, Dr. Spencer Thomson of Torquay, who has forwarded me a subscription, I have to request those willing to assist in this fund to kindly send their contributions to me at once.

JOHN WOODMAN, F.R.C.S.,
Hon. Sec. S.W. Branch.

2, Chichester Place, Exeter, March 29th, 1875.

REPORTS OF SOCIETIES.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

WEDNESDAY, MARCH 10th, 1875.

W. R. E. SMART, M.D., C.B., Inspector-General R.N., President, in the Chair.

On some Arithmetical Questions involved in the Rise and Progress of Epidemics. By G. H. EVANS, M.A., M.D.—Dr. EVANS had been led to interest himself in the mathematical expressions of the course of epidemics by observing the success with which Dr. Farr had, in January 1866, foretold that the epidemic of cattle-plague then increasing might be expected shortly to decline. The prediction, closely justified by the event, was based on the observation, that the increase for the three previous weeks was not uniform, but at a decreasing rate; so that, by the same progression, the weekly number of attacks must soon reach a maximum, and thenceforth decline. Dr. Evans explained the process by which, from a given portion of a series, further members of the series might be calculated, and went on to consider how far the method applied to some of our own ordinary epidemics might be available for the practical sanitarian. By way of illustration, he had examined the behaviour of cholera and scarlet fever in London; and he showed a number of charts in which he had inserted diagrammatically the actual weekly course of an epidemic, from its beginning to its end, along with the hypothetical course reckoned for the several weeks from the data afforded by the earlier portion of the outbreak. On several of these charts, there was a noticeable correspondence between the actual and the calculated progress of the disease investigated; and it was evident that, at some period during the rise of most epidemics, there was to be found a rate of progress from which might be deduced a series conforming very fairly to the actual numbers that are about to follow. Dr. Evans's illustrations showed, however, that the rate of progress during an increasing epidemic altered very materially within short spaces of time; so that, if calculated from a particular group of weeks, if too near the commencement, an excess obviously erroneous would result; if calculated at too late a period, the error would be on the side of defect; but, from certain weeks of its course, a calculation could be made which would be fairly justified by the facts. The illustrations showed that the data yielding the best forecasts of an epidemic were not derivable from its earliest weeks, but rather (as indeed might have been expected) from the weeks when the epidemic was tending to its culmination. Hitherto, however, he had obtained no indication to guide him in the selection of this particular period; hence, while admitting the value of the method for the purposes to which Dr. Farr had applied it, he could not at present say how to adapt it to general use as a means of predicting what the course of an epidemic would be at that part of it where such knowledge would be of most practical value. Dr. BUCHANAN, in proposing the Society's thanks to Dr. Evans, referred to the great expenditure of time and skill that had been given to the establishment of the epidemic "curves" by which the paper was illustrated, and to the careful reasoning that had characterised Dr. Evans's conclusions. The result, though instructive, was disappointing so far as immediate practical application was in question. He had hoped that, from the earlier course of a given epidemic, it might have been found possible to predicate, on the constancy of the causative elements, what the further course of the epidemic would be; so that, by comparison of the actually observed course with the computed subsequent course, it might be possible to establish the presence or absence of some disturbing influence exercised over the epidemic. Sanitary workers sought to exercise such an in-

fluence, and it would be a great advantage to them to know for certain the fact of their success or failure; and to have a measure of the degree of any success that, by the use of this or that preventive measure, they might gain. From Dr. Evans's calculations, it appeared that one particular period of a rising epidemic must be taken, if the estimated further progress were to agree with the actual further progress; that this period could not begin a week earlier or a week later without large discrepancy between the calculated and the actual; and that at present there was no sufficient indication during the rise of an epidemic of when the safe time for prediction was reached.—Mr. J. NETTEN RADCLIFFE, in seconding the proposition, said that he was impressed with a much more hopeful and favourable view of the results attainable by this arithmetical method. Dr. Evans's calculated curves agreed very closely with the after-course of the epidemics he had investigated when the right part of it was hit upon. Now, if a definite series for one part of an epidemic can be found, we are near a law for the whole. The present difficulty seemed to be in defining when a disease ought to be considered epidemic. He wished to express his intense gratification in the interest of scientific epidemiology that Dr. Evans had favoured the Society with so valuable a paper, embodying the results of his mathematical calculations.—Inspector-General LAWSON differed from Dr. Evans in considering that the results he had obtained were unimportant, because they were to a great extent negative. The author represented the progress of an epidemic (as shown by the deaths from it) by a curve, and, finding a formula representing part of that curve, expected to complete it, and so anticipate the progress of the disease, both as to intensity and duration. This he would do, if the forces concerned in developing the epidemic remained the same, and acted in the same directions throughout the continuance of the epidemic; but more causes were active in generating epidemics than were generally taken into account. Those acted at different times and with varying force, or had their action interfered with or suspended by the intrusion of others not yet recognised. Until we were better acquainted with the different factors concerned, there was little prospect of being able to avail ourselves to any great extent of mathematical formulae to predict the course of epidemics, or to facilitate the arrangement of the information now possessed regarding them.—Dr. EVANS, in reply, said that Mr. Radcliffe's observation exactly applied to the great difficulty he had felt throughout the inquiry; viz., that of finding out when a disease really became epidemic. If the point could be determined from which epidemic progress commenced, we could then obtain a ratio; it might be one differing by constant differences. An epidemic did not begin with the first rise above the average mortality: in taking the mortality of some of the earlier weeks of the late epidemic of scarlet fever in London, quite impossible results were arrived at, and some other curve had to be sought from the mortality registered a few weeks later. Each of the scarlet fever epidemics investigated culminated between the fortieth and forty-seventh weeks of the year; that is to say, in October or November. The disturbing forces alluded to by Mr. Lawson influenced much the course of epidemics, and no doubt the curve was greatly modified by three conditions: 1. The more susceptible were first seized; 2. A previous attack often conferred immunity; 3. The intensity of the virus was eliminated by transmission. Those increased the difficulty of the inquiry. It might be possible by more labour to arrive at trustworthy and useful results.

MANCHESTER MEDICAL SOCIETY.

FRIDAY, FEBRUARY 3RD, 1875.

J. E. MORGAN, M.D., President, in the Chair.

Tumour of the Brain.—Dr. DRESCHFELD showed a brain with a small tumour of the size of a filbert, situated at the base in the median line, immediately in front of the pons Varolii. It was rounded in outline, of firm texture, and composed almost entirely of small spindle cells. The patient from whom the specimen was obtained was admitted as an in-patient of the Infirmary on September 12th, 1874, complaining of dizziness in his head, dimness of vision, and displaying considerable emotional disturbance, laughing and crying alternately. There was also weakness of the arms and legs. The eyes were examined, and appeared normal. As the disease progressed, he felt less confidence in walking, and if he stopped or turned suddenly, seemed inclined to fall. His sight became double, and at last almost total blindness set in. His speech became thicker, and just before death he was unable to swallow. His temperature rose, and he became delirious.

Multiple Sarcomata.—Dr. HARDIE showed a man with multiple sarcomatous tumours affecting the skin of the trunk.

Abnormal Appendix of Bowel.—Dr. BALL showed a specimen of an abnormal appendix to the bowel. It was obtained from a boy aged 12,

admitted into the Stockport Infirmary, December 24th, 1874. He always had been subject to attacks of obstinate constipation, with tympany and abdominal distension. These attacks were of frequent occurrence, he seldom being free from them for more than a month or five weeks. The present attack had lasted for nine days, during which there had been no action of the bowels, but gradually increasing tympanites and vomiting. The boy was pale, feeble, and emaciated, with an anxious expression of countenance. The abdomen was immensely distended, and the outline of the bowels could be seen under the skin. There was frequent vomiting of a fecal or semi-faecal fluid. An injection of castor-oil and turpentine brought away a small piece of hardened feces. A tube was introduced twelve or fourteen inches up the bowel. The injection was repeated, but with no better result than before. Inability to void urine came on, and it was found impossible to pass any but a flexible catheter. An examination *per rectum* was made, and a large doughy tumour, pitting on pressure, and then slowly recovering its shape, was found occupying the position of a distended bladder. The boy sank and died nineteen hours after admission. At a *post mortem* examination, twenty-nine hours afterwards, the abdominal cavity appeared to be almost completely filled with immensely distended large intestines, which pushed the bladder into the left iliac fossa. The large intestine, on a more minute examination, was found to consist from caecum to anus of a double tube; the posterior, continuous with the small intestine, being of ordinary size, the anterior ending in a *cul-de-sac* at each extremity, the only communication between the two being by several oval foramina, about large enough to admit the end of a finger, placed at irregular intervals about twelve inches from the caecum. The septum between the two was thin at the upper part, but became more dense near the anus. The supplemental part was filled with an immense quantity of fecal matter of the consistency of mashed potatoes, the true bowel containing some similar matter, but in much less quantity. The small intestines and other organs were healthy. Microscopic examination showed that the wall of the extra tube consisted chiefly of muscular tissue. Dr. Ball said that, as far as he was aware, this was the only recorded example of this abnormality.

Melanotic Tumour of the Orbit: Removal: Recurrence of Cancer.—Dr. GLASCOTT showed the case of a man aged 40, from whose orbit he had ten months ago removed a melanotic tumour. Six months afterwards, there was no recurrence. Two months ago, he presented himself with another tumour, which was growing rapidly, and had filled the orbit. Since then, numerous nodules of cancer had made their appearance under the skin, and had continued to appear with great rapidity, until the whole body, with the exception of the legs and the forearms, was studded over with secondary deposits, varying from the size of a bean to that of a pigeon's egg. He had previously been perfectly healthy, and no hereditary taint could be traced.

Tuberculous Ulcers of the Ileum.—Dr. MORGAN showed an ileum studded with several very characteristic tubercular ulcers. The mucous membrane of the colon was also extensively disintegrated, and the walls much thickened.

Diseased Kidneys.—Mr. LUND exhibited the kidneys of an old man aged 72, who had suppression of urine from a mechanical cause. He was admitted into the Infirmary with a phosphatic calculus in the bladder. Lithotrity was contemplated, but suppression of urine took place, and the patient died comatose. One kidney was found to be completely disorganised, and the ureter of the other blocked up with some sabulous matter.

Mitral Stenosis.—Mr. JONES exhibited a heart with mitral stenosis. The orifice would admit the tip of the little finger, and bridging across it was a thin round fibrous cord.

MEDICAL MICROSCOPICAL SOCIETY.

FRIDAY, FEBRUARY 19TH, 1875.

J. F. PAYNE, M.B., President, in the Chair.

Natural Method of Mounting Microscopic Specimens.—Dr. W. R. WOODMAN read a paper on a natural method of mounting certain microscopic specimens. It consisted of putting up urinary deposits, sputa, etc., in their mother liquor, with or without the addition of a few drops of a concentrated solution of crystallised carbolic acid, and then thoroughly cementing round the edge of the cover-glass with any good cement. Dr. Woodman had specimens which had been preserved in this way for more than fourteen years without alteration. Epithelial casts were said to keep very well if put up in this fashion for some months, but they eventually became deteriorated. Dr. Woodman did not consider that asphaltic varnish deserved all the abuse it got.—Dr. PRITCHARD objected to asphaltic, unless prepared as Mr. Miller used

it, by drying and redissolving in dammar varnish.—Mr. F. DURHAM and Mr. GROVES thought that asphalt and gold size in equal proportions formed a good tough cement.—The PRESIDENT preferred Frankfort cement.

Marking of Specimens.—Mr. NEEDHAM described a method he adopted for marking specimens in hardening or preservative solutions by the use of coloured glass beads—black representing No. 1, red No. 5, green No. 10, etc.; so that, by a combination, any numbers could be produced. A numbered record of all preparations was kept in a note-book, so that any specimen could be found with ease.

Swiss Gauge.—Mr. F. H. WARD exhibited and described a Swiss gauge which he used for measuring the thickness of covering glass.

The meeting terminated with the exhibition of a number of specimens.

FRIDAY, MARCH 19TH, 1875.

J. F. PAYNE, M.B., President, in the Chair.

Spinal Cord in Infantile Convulsions.—Specimens were exhibited by Dr. SIDNEY COUPLAND, taken from a child aged six months, who died in convulsions consequent upon cancrum oris. There was found great dilatation of the capillaries and small vessels of the cord, especially in the commissural part of the grey cornua and enlarged perivascular spaces, the maximum of enlargement being in the lower part of the medulla, particularly near the central canal; but the canal itself and its epithelial lining were quite healthy. The appearance resembled that described by Dr. Dickinson in certain cases of diabetes. Dr. Coupland thought that the enlarged perivascular spaces were secondary to over-distension of the vessels.—The PRESIDENT suggested wasting of the brain as a more probable cause for the enlarged spaces, and that they were the tunica adventitia separated from the artery.

Urate of Soda in the Heart.—Mr. WARD showed a specimen of plugging of the coronary artery, studded with crystals of urate of soda. It was taken from an old case of gout. Death was sudden, from ruptured left ventricle. There was no fatty change, but the heart substance was friable.—Dr. GREENFIELD stated that fatty change often followed plugging of the coronary artery.—Mr. GOLDING BIRD asked if any chemical test had been applied to the crystals; he had once succeeded in obtaining crystals of uric acid under the microscope from crystals of urate of soda in gouty cartilage by the addition of weak acid.—Mr. WARD, in reply, had named the crystals from their shape only.

Myxoma.—A section in glycerine by the President showed the connecting processes to be rather tubular, than flattened and folded up in a gutter-like form, as usually described.

CORRESPONDENCE.

DR. RUMSEY.

SIR,—Dr. Henry W. Rumsey of Cheltenham has just retired in consequence of a severe attack of illness, which disables him from continuing his practice; and it is thought by many that this is a favourable opportunity for expressing their appreciation of his services to the sanitary cause, to the profession, and to the public. A sketch of his labours, extending over the greater part of his career, and of his consequent claims, has been drawn up, and is now in circulation.

I first met Dr. Rumsey before a Committee of the House of Commons, pleading at once for the poor and for the Poor-law medical officers. He was associated with his intimate friend Robert Ceely of Aylesbury; and to the energetic action of these two men, acting in concert with the Provincial and the British Medical Associations, and the press, the progressive improvement in the medical relief of the poor owes its origin. He took an active part in the endeavours of those who were seeking to put provident societies on a sound footing. Dr. Rumsey wrote on the health and sickness of town-populations (1846), and in the year 1856 published his classical volume of *Essays on State Medicine*, which was followed year after year by a series of striking papers on sanitary science and administration. Dr. Rumsey is a scholar; and his writings, remarkable for clearness of exposition and originality of view, have undoubtedly contributed to impress the Legislature with its present views of the importance of public hygiene, which, like every good cause, has had to encounter hostility. If a sagacious Prime Minister has given the world the new reading

of "*sanitas sanitatum*", Dr. Rumsey has some claim to the credit of party enlightenment. But Dr. Rumsey began his labours in an age of indifference for the cause, which is only beginning to triumph when he is cruelly struck down.

Some persons held that public health is an affair that can be handled by nuisance-inspectors. Dr. Rumsey, on the contrary, saw clearly that the public health could be best dealt with by specially educated medical men, well versed in science; and it is his great merit, that in the General Medical Council, as well as elsewhere, he sought to obtain a special qualification for State Medicine from the Examining Bodies. This would be in all time to come a guarantee of competency to the public; while it would open great careers to eminent State physicians, proceeding on the lines laid down by the Father of Medicine. One of the last papers I heard by Dr. Rumsey was on this very subject.

Dr. Rumsey, its Chairman, was in constant correspondence with the Joint Committee of the Social Science and the British Medical Associations; he spared no labour, and frequently at the sacrifice of his professional time came to London. His correspondence on public matters was unintermittent. Among many other avocations, Dr. Rumsey was a vigilant sanitary critic. He criticised freely the Legislature, the Government, the public offices, including that with which I am concerned, and the registration of vital statistics. On some of these subjects he was, I think, wrong; at least, I differed from him; but I do not hesitate to say that his criticisms were often beneficial, were animated by public spirit, and were characterised by fearless honesty of purpose.

During his career, Dr. Rumsey has received many honorary marks of the appreciation of the profession; and has been recently elected a Fellow of the Royal Society. But, at the close of thirty-seven years, full of his labours for public objects and professional interests—in which he has expended much and received nothing—it does appear to me, that if Dr. Rumsey was still in the vigour of his life, the time has come when some substantial testimonial might be presented to him. Such a step could only tend to encourage men to devote themselves to the public service. And now that Dr. Rumsey, after climbing the steep side of the hill, is smitten down before he can enjoy the full fruits of professional fame, his claim is enhanced. He is a man of whom we may be justly proud. And the appeal now made in the name of that noble fraternity which binds the profession together as one body cannot be in vain. He will receive the crown he has won at last.

The British Medical Association and the Social Science Association, at the meetings of which Dr. Rumsey has presided in the Health Sections, will probably turn their admirable organisations to account in favour of the movement.

A Central Committee has been formed in London, including the most eminent men; and now it is proposed to invite leading members of the profession in the provinces to establish corresponding Committees, and their support will, I doubt not, be afforded. Dr. Rumsey himself, practising in the provinces, was one of their brilliant ornaments, and one of the most strenuous assertors of their claims and rights.

I have the honour to be, Sir, yours faithfully,
WILLIAM FARR, Chairman of the Central Committee.
General Register Office, Somerset House,
London, 12th March, 1875.

THE CONTAGIOUS DISEASES ACTS.

SIR,—The statistics of venereal disease among the Royal Engineers at Chatham, in the years 1800-74 inclusive, cannot be too widely known; and I, therefore, feel obliged to Dr. Nevins for publishing them in a graphic form. I must, however, object to his excluding the year 1874; neither he nor I nor any other man knows with certainty whether the new Regulation of 1873 had any effect; and there is, therefore, no evidence on which this year can be excluded. In reproducing the figures of another person, a writer ought, I conceive, to do

so textually. I must, therefore, ask your readers to add to the graphic representation another column for the year 1874, and to run a long sloping line down with the number 23.7 at the end of it for syphilis, and a short sloping line for gonorrhœa with the number 63.3.

In his analysis of these figures, Dr. Nevins virtually repeats his former argument, to which I have already replied. Instead of following him again, allow me to restate the simple facts of the case. Syphilis is a disease of yearly fluctuations; it has always been so, and will, no doubt, continue to be so, from causes too obvious to need stating here. Consequently, a comparison between single years, in Dr. Nevins's method, is highly insecure, and long periods must, if possible, be taken. As the statistical returns of the army in their present form only commenced sixteen years ago, and the first year is deficient, the Royal Engineer statistics give us the longest available periods; viz., six years before the Contagious Diseases Acts were passed and nine years afterwards; and if the first three of these nine years are taken out, as it was a time of transition, we have two comparable periods of six years—1860-65 and 1869-74. In both periods there are fluctuations to a certain extent, but there is this great difference. In the first six years period (before the Acts), the yearly fluctuations are from 109.3, the highest, to 74.8, the lowest; in the second period (under the Acts), the fluctuations are from 76, the highest, to 23.7, the lowest, or to 44.3 if the year 1874 be excluded. Consequently the *highest* yearly admissions in the second period are almost the same as the *lowest* yearly admissions in the first period, and the lowest admissions in the second period are less than one half the lowest admissions in the first period. The means again of the two six years periods are 93.2 admissions per 1,000 of strength before the Acts, and 53.1 under the Acts.

Now, these are the simple figures of the prevalence of primary syphilis; those of gonorrhœa I omit on account of space. However Dr. Nevins may construe them, he cannot take away their force. There they are, as exact as a chemical experiment, and entitled to as much credence.

When Dr. Nevins says that, in looking at the charts, no one can say when a new agent came into operation, I must deny the accuracy of his statement. Looking to the usual amount of fluctuation and to the height of the curve before the Acts, and then to the corresponding curve after the Acts, I cannot myself conceive anyone can doubt that in the last six years some conditions tending to powerfully depress venereal admissions were in action.

The dispute must be, I conceive, not as to the reduction but as to its cause. Now, the Royal Engineers were in the same barracks, under the same sanitary conditions in both periods; neither the strength nor the recruiting, nor any other condition of the kind, gives any clue. There was no difference, in fact, between the two periods, except that in one case syphilitic women were under no check, and in the other the women were examined and prevented from spreading syphilis if found diseased. The facts are certain, and the explanation is most probable; it is, indeed, the only possible explanation. I thank Dr. Nevins, therefore, for so kindly allowing these striking facts to be again stated, and I think in this, as in other ways, he has unconsciously very much strengthened the arguments for maintaining the Acts. With your permission, sir, I should like to be allowed to bring before your readers a short summary of the statistical evidence on this subject which has been lately given in your columns and in those of your contemporaries.

Netley, March 27th, 1875. I am, etc., E. A. PARKES, M.D.

SIR,—Dr. Nevins states that it would be impossible for anyone examining the curve of his diagram indicating the rise and fall of syphilis and gonorrhœa to fix upon the period of time in which a new agent came into operation and showed itself of marked sanitary value upon the future progress of the disease. Now, it appears to me that anyone must at once perceive that, after the temporary rise in the lines in the year 1867, the fall in both diseases was greater, and the average lowness of it more steadily maintained than in the previous years. Taking the number of cases of syphilis per 1,000 for the six years preceding 1866, we get an average of 93½, while the average for the eight years subsequent to 1866 is only 67. The average in gonorrhœa in six years before 1866 is 141½; for eight years after 1866, 94½.

If Dr. Nevins will give the continuation of his line for another eight years, I have not the slightest doubt that the steady progress downward will be maintained, and that it will leave off as much below 44.6 as that was below 108.

If Dr. Nevins, instead of serving up the same figures again and again in different dressings, would visit the places where the Acts are in operation and gain some practical acquaintance with the subject from those capable of giving him information, his treatment of the subject would have more weight.

My own experience at the Liverpool workhouse, where for some years we have adopted, with men and women both, compulsory retention till cure, has been that not only the extent but the character of the disease has been materially modified; and I cannot but conceive that early isolation and active treatment must have the same effect whenever or wherever carried out.

I am, sir, yours obediently, J. H. BARNES.
57, Pembroke Place, Liverpool, March 27th, 1875.

MILITARY AND NAVAL MEDICAL SERVICES.

MOVEMENTS OF ARMY MEDICAL OFFICERS.—Surgeon-Major J. S. Comyn, M.B., is appointed to medical charge 1st Battalion 21st Fusiliers; Surgeon T. Kingston, M.D., to do duty 107th Regiment, Secunderabad; Surgeon A. Kirwan, to do duty 107th Regiment, Secunderabad; Surgeon C. C. H. Smith, M.D., to general duty, Madras Presidency Circle; Surgeon-Major Cooper, M.D., from 5th Regiment, N.I., to 2nd Regiment Light Cavalry, vice Surgeon-Major W. A. Smith, vacated; Surgeon J. M. Donnelly, M.D., from attached 1st Regiment Light Cavalry to 7th Regiment, N.I., but to continue with the Cavalry; Surgeon F. H. Blenkinsop, from attached 5th Regiment, N.I., to 5th Regiment, N.I.; Surgeon P. H. Benson, to do duty General Hospital, Madras, to do duty Lying-in-Hospital, Madras; Surgeon W. J. Charlton, from doing duty 45th Regiment, to do duty 1st Battalion 21st Fusiliers, to join on arrival of the corps at Rangoon.—Deputy Surgeon-General Woolfreyes, who served for some time in Dublin Garrison, has been appointed to the medical charge of the Western District; Surgeon-Major R. Tate, attached to the 2nd Battalion 2nd Queen's, has returned to the Royal Barracks from leave of absence, and resumed his duty; Surgeon-Major A. P. Cahill, M.D., has arrived home from Ceylon after a long service in that command.—Surgeon-Major T. E. P. Martin, secretary to the surgeon-general, has obtained furlough to Europe for two years, from date of departure in May next.—Surgeon H. J. Linton, Bengal Medical Establishment, is allowed to proceed to Europe, on medical certificate, in anticipation of furlough.—Surgeon J. H. Ritchie, Madras Medical Establishment, is allowed to proceed to Europe, on medical certificate, in anticipation of furlough.

THE DIFFICULTIES OF ARMY MEDICAL REFORM.

SIR,—In your remarks upon the "Obstacles to Army Medical Reform", arising from want of unanimity in the expressed views of medical officers, you have touched upon a real practical difficulty; one, however, which is capable of reasonable solution. You have very correctly divided the whole department into three groups, viz., the upholders of the regimental system, the advocates of the staff scheme, and the proposers of a mixed plan, but you have not indicated what numerical proportions they bear to each other; whereas further investigation would show that the first is to the second in about the same ratio as the eleven obstinate jurymen to the unconvinced one, while the third is in reality a section of the first, ready to embrace any compromise for the purpose of saving a moiety of the original system. It is, therefore, evident that a very large majority are conservative of the old state of things, while the minority support the new régime.

Now, it does not of necessity follow that the many cannot err, and still less so in this instance, in which the officer highest in rank, and whose opportunities for forming a correct judgment have been so extended, holds the opinion of the minority. On the contrary, believing in the unswerving probity and disinterestedness of the efforts of the Director-General on behalf of his department, I conceive that it is the duty of every medical officer to accept with all submission the change of organisation which our representative has deemed it right to advise, *provided* that he assures his subordinates that the full spirit and form of his recommendations have been embodied in the new regulations. On the other hand, I hold that it is equally a point of honour on the part of the Director-General, should he find his proposals to be altered and emasculated by those for whose approval they have to be submitted, to withdraw from all endeavour to force a bastard system upon an unwilling department.

Now, we have of late been repeatedly informed, in almost demi-official tones by your contemporary the *Lancet*, that the intention of the originators of the staff scheme must not be judged by the results attained, and that they themselves can scarcely identify the outline even of their own conception. Under these circumstances, it is but seeking common justice to demand that, by all its promoters, this graceless mongrel scheme should be disowned.

Thus I think discord can be reduced to concord in five requirements :
 1. A complete return to the regimental system. 2. Superannuation of the Surgeon-Generals and Deputy Surgeon-Generals at sixty years of age. 3. Superannuation of Surgeon-Majors at fifty-five years of age. 4. Optional retirement at twenty years on fifteen shillings a day. 5. Guaranteed promotion at fifteen years' service.—I am etc.,

HARMONY.

DR. E. HAMILTON'S STATISTICS.

SIR,—In a letter in the *Lancet* of January 30th, Mr. Boileau attempts to defend Dr. Edward Hamilton's statistics, commented upon in this JOURNAL, in reference to the comparative expense of promotion of army surgeons at twelve years' and at fifteen years' service. In doing so, he gives Dr. Hamilton credit for more accuracy than he deserves, and at the same time does not perceive that his own more accurate figures furnish a severe commentary upon that gentleman's statistical vagaries. He shows (as was done in this JOURNAL already) that there is an excess of expenditure every year in the twelve-years' system, instead of a positive saving after some years, as preposterously stated in the pamphlet in question. Mr. Boileau, however, manages to make it appear that Dr. Hamilton's figures are nearer the truth by an ingenious process. 1. He calculates the bare difference of pay, and adds 8d. a day, or the difference of the lodging-allowance only. 2. He calculates the annual decrement at 4 per cent. Now, Dr. Hamilton supposed a difference of 5s. a day of allowances (instead of 8d.), and calculated the decrement at 3 per cent., which would make the sum of £4,715 *per annum* (supposed by Mr. Boileau to be the probable annual expense) more than £11,000. It is true that, just at the end of his letter, he admits that, if the forage-allowance be guaranteed, the expense will be £8,164; but states that, after the next twelve years, it will be much less. It has already been shown in this JOURNAL that the expense for the next eleven years will be £9,300 annually (as an average), calculating the decrement at 3 per cent.; and that the final constant difference would be about £8,100, below which it would not fall. Mr. Boileau's method is correct, but his application of the results is wrong. I am, sir, yours obediently, STATISTIC.

REORGANISATION OF THE ARMY MEDICAL DEPARTMENT.

A PRINTED paper containing the following "Suggestions for the Reorganisation of the Army Medical Department" has been forwarded to us. It is stated that they have been submitted to a large number of Army Medical Officers, and that they have been carefully revised and fully approved of by them. They appear to have been drawn up in an impartial spirit, with a view to an equal participation of all medical officers in the provisions contained in them, and not for the benefit of any particular section of the medical department, as seems to have been the case in some of the schemes brought to the notice of the profession recently. We would only inquire whether a calculation has been made of the cost that would be incurred in carrying out suggestions Nos. 13 and 15. We imagine that the forced retirement of all officers of the administrative ranks at sixty years, on the terms named, would involve a larger outlay in retiring pensions and fresh appointments than is generally supposed; but it may yet not be too large a sum, if its expenditure will secure a steady course of promotion, and a more contented state of mind in all ranks of the army medical department. With this remark we place the suggestions themselves before our readers, in the order in which they have been sent to us.

1. Department to be styled the "Royal Medical Staff Corps", and all officers to be executive as far as the command of the Army Hospital Corps is concerned, both as regards officers and men.—2. Promotion to the rank of surgeon-major to be fixed at fifteen years' full pay service at latest, but to be earlier if possible, e.g., in time of war.—3. All medical officers ranking as field officers to be entitled to forage as laid down in the warrant of 1858.—4. Every officer to be entitled to sixty-one days' leave in the year on full pay and allowances; the arrangements for the performance of his duties to be made by the administration of the "Royal Medical Staff Corps".—5. Officers requiring additional leave on urgent grounds, to be granted it on pay only, without allowances.—6. Medical officers to be placed on the same footing as officers of the rest of the army as regards sick leave.—7. Medical officers, no matter how employed, to have a fixed scale of allowances, which shall only bear one interpretation, subject, however, to deductions on a fair scale, when quarters, servants, or forage, etc., are supplied by government. Servants' allowance to be 1s. 6d. *per diem*.—8. Medical officers attached for any period to regiments, to pay the usual monthly subscriptions to the mess, but not to be liable for the

fifty days' pay donation on first joining.—9. All medical officers to be placed on one roster for foreign service, and to go abroad in their turn, irrespective of any appointment they may be holding.—10. Exchanges to be allowed, and to be *bonâ fide*: the officer staying at home to take up the post vacated by the officer going abroad.—11. Medical officers to be relieved of all the duties properly belonging to purveyors; subordinates for that purpose being placed under the orders of the principal medical officer in the station, and being responsible to him for all stores.—12. The Royal Medical Staff Corps to have sole charge of and control in the military hospitals, subject only to the authority of the general commanding officer.—13. Retirement of officers of the administrative ranks to be obligatory at sixty years of age, and on more liberal terms—say 35s. a day for deputy-surgeon-general, and £2 for surgeon-general.—14. Tenure of office for administrative ranks to be limited to five years in each grade, or ten years in the two: officers so retired to receive the maximum rate of half-pay. All other official appointments (except that of director-general) to be limited to five years.—15. Surgeons-major to be allowed to retire after 20 years' full pay service on 16s. a day, to be increased by yearly increments of 1s. *per diem* for each subsequent year's service, till the maximum pension of 26s. a day is obtainable, e.g., £1 1s. at 25 years' service, and £1 6s. after 30 years, and not to be dependent on medical boards.—16. Officers retiring through ill health, caused in or by the service, to be allowed a higher rate of retirement, according to the recommendation of a medical board.—17. Officers retiring from ill health before the completion of twenty years' service, to be granted seven-tenths of the pay they were drawing, when invalided.—18. Surgeons-major after twenty years' service, to rank as lieutenant-colonels, deputy-surgeons-general as colonels, and surgeons-general as major-generals, according to date of commission.—19th. Distinctive staff dress: tunic, patrol jacket, mess jacket and waistcoat, full dress trousers, sword and dress belts as at present. Substitute staff forage cap, and staff undress trousers for those now in use. Abolish the black belts, and substitute some other head dress for the cocked hat, except for the administrative ranks.—20. A guarantee be given that whatever terms favourable to the department be now granted, shall not be interfered with or nullified by subsequent circulars.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

REGISTRARS' FEES FOR SANITARY PURPOSES.

NEARLY all the metropolitan parishes have been compelled to accede to the suggestion of the Registrar-General that they should pay the registrars of births and deaths for the weekly returns supplied to the medical officers of health for sanitary purposes. Those parishes which resisted the Registrar-General's reasonable proposal that the registrars should supply the number of births registered each week in their respective districts gratuitously, and be paid £1 per quarter for the first fifty, and one penny for each subsequent entry, have been compelled to pay in some instances nearly double to the registrars, as they cannot get their returns from the Registrar-General. Paddington has consented to pay 25s. per quarter for the first fifty, and 2d. for each additional entry. The St. Pancras registrars have agreed to accept £1 for the first fifty deaths, and 2d. for each subsequent entry per quarter. In Marylebone, a somewhat similar arrangement has been made; but in some of the parishes, as much as 30s. for the first fifty, and 3d. for each subsequent entry, is demanded by the district registrars.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

HASTINGS (URBAN) SANITARY AUTHORITY.—The Medical Officer of Health's last quarterly report contains also a "Retrospect for 1874". From Mr. Ashenden's calculations, it appears that the death-rate of Hastings last year was hardly at the rate of 18 per 1,000 *per annum*. The birth-rate for the same period was 20.8, or 6 below the average for England and Wales. Phthisis and cancer each contributed largely, viz., 83 and 24 deaths respectively, to the general death-rate. It would be interesting to know how many of these cases of phthisis and cancer were imported ones. The births amounted to 902, the deaths, at all ages, to 602 (112 being visitors); and 120 children died under one year of age, and 232 under five. Zymotic disorders contributed a sixth of the total number of deaths; so it would appear that Hastings has not yet arrived at anything like sanitary perfection. Of this sixth, "whooping-cough" contributed 32 deaths, and "croup" 18; diphtheria, 6; measles, 11;

and scarlet fever, 4. There were 13 deaths from violence. "The borough," says Mr. Ashenden, "has been free from any epidemic." This hardly tallies with the above figures; but it is gratifying to learn how the judicious use of disinfectants, and the isolation of fever-cases, kept scarlet fever within narrow bounds. Mr. Ashenden recommends the sanitary authority to erect an infection hospital of their own, and to provide a disinfecting apparatus and a sanitary vehicle. We hope they will follow his wise counsel.

It seems that at Hastings "bell-traps" are relied upon to keep out sewer-gas from houses. The sooner these wretched traps are discarded, and thorough disconnection from drains and outside trapping adopted, the better for Hastings, notwithstanding the belief that "there is no town in England where the drainage is so satisfactorily carried out, and the ventilators of each, with its disinfecting apparatus fulfil their purpose admirably." It is evident that a perusal of Drs. Parkes and Sanderson's report on Liverpool would teach the Hastings Sanitary authority some useful lessons. The water-supply appears to be derived from wells and from waterworks also. Out of fifty-four samples of water, Mr. Ashenden has condemned twenty as unwholesome, and he evidently considers that the list might be enlarged. More than twenty gallons per head daily are now supplied from the waterworks, but we cannot altogether endorse Mr. Ashenden's advice to the consumers "to have their cisterns large enough". The well from which St. Leonard's is chiefly supplied is stated to be "a splendid water".

As to the meteorology of Hastings, Mr. Ashenden endeavours to show the superiority of its climate to that of other watering-places. Nevertheless there were recorded in 1874, forty-two deaths from bronchitis, and twenty-eight from pneumonia.

SWANSEA (RURAL) SANITARY AUTHORITY.—From Mr. Rogers's two reports, December 6th, 1874, and February 3rd, 1875, it appears that his district has been suffering rather severely from scarlet fever. Mr. Rogers does not state what steps are taken by the sanitary authority to combat the epidemic, but his reports are mainly occupied with statistics. The population of the district is not stated, but it is stated that there were nine deaths in the month of December from scarlet fever, and seven in January.

POOR-LAW MEDICAL APPOINTMENTS.

MACNAUGHTON, John, M.B., appointed Parochial Medical Officer to the Kilmeachal District of Glassary Parish, Lochgilphead, *vice* W. Dougan, M.D., resigned.
 SYMONS, George S., M.R.C.S. Eng., appointed Resident Medical Officer to the Chorlton Union Workhouse, *vice* D. Walshe, L.K.Q.C.P.I., resigned.
 TOPP, John George, L.R.C.P. Ed., appointed Medical Officer and Public Vaccinator for the Evers Green District of the Auckland Union, Durham, *vice* H. G. Hardy, L.R.C.P. Ed., deceased.

APPOINTMENTS OF CONSULTING MEDICAL OFFICERS OF HEALTH IN IRELAND.

REID, James Seaton, M.D., appointed Consulting Sanitary Officer for the Belfast Rural Sanitary District.
 RUSSELL, John, L.K.Q.C.P.I., appointed Consulting Sanitary Officer for the Thurles Rural Sanitary District.
 RYAN, John, M.D., appointed Consulting Sanitary Officer for the Killadysert Rural Sanitary District.
 STERLING, Miles, L.R.C.S.I., appointed Consulting Sanitary Officer for the Thomastown Rural Sanitary District.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF OXFORD.

MAGDALEN COLLEGE: DEMYSHIPS AND EXHIBITION.—There will be an election at this College in June next to not less than six demyships and one exhibition. Of the demyships, one at least will be mathematical, one at least in natural science, and the rest classical. The exhibition will be in natural science. No person will be eligible for the demyships who will have attained the age of twenty years on the 10th of October next. Candidates for the exhibition will have to prove to the electors that they cannot be supported at College without such assistance. They will not be eligible after the age of twenty-three. The stipend of the demyships is £95 *per annum*, and of the exhibition £75, inclusive of all allowances; and they are tenable for five years, provided that the holder does not accept any appointment which in the judgment of the electors will interfere with the completion of his University studies. Testimonials of good conduct will be required, and a certificate of birth, which must be presented to the President on Monday, June 14th, between the hours of four and six, or eight and nine P.M. The examination will commence on the following day. Particulars relating to the examinations in the various subjects may be obtained by applying to the senior tutor.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, March 25th, 1875.

Day, Edward Joseph, Woodgates, Dorset.
 Karop, George Charles, Middlesex Hospital.
 Prichard, Arthur William, Clifton, Bristol.
 Seward, William Joseph, Hereford.
 Wilkins, Gilbert Hamilton, 112, Brixton Road.

The following gentlemen also on the same day passed their primary professional examination.

Angove, William Thomas, St. Bartholomew's Hospital.
 Birt, Louis Francis Hugh, Charing Cross.
 Blackman, Joseph George, Charing Cross.
 Hill, Alfred Bostock, Birmingham.
 Maine, Walter, Middlesex Hospital.
 Price, Ebenezer Edmund, Middlesex Hospital.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the monthly examination, held on Tuesday, Wednesday, and Thursday, March 9th, 10th, and 11th, 1875, the License to Practise Medicine was granted to—

Messrs. Robert Alexander Caldwell, John Clifford, Albert Cray, Henry Fuzillibon, Abraham Nickson Hojel, Thomas Knox, Charles Sidney Richardson, Ernest Marcus Thompson.

The License to Practise Midwifery was obtained by—

Messrs. John Blood, Robert Alexander Caldwell, John Clifford, Albert Cray, John Arthur Irwin, Thomas Knox, Charles Ferdinand Marks, Charles Sidney Richardson, James Charles Stoyte, Ernest Marcus Thompson.

MEDICAL VACANCIES.

The following vacancies are announced:—

BARTON-UPON-IRWELL UNION—Medical Officer for the Cadishead D's-trict. Salary, £35 *per annum*.
 BETHLEM HOSPITAL—Two Resident Medical Students.
 BOLTON UNION—Medical Officer for the Horwich District. Salary, £30 *per annum*.
 BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 12th.
 BRISTOL ROYAL INFIRMARY—Dispenser. Salary, from £100 to £120 *per annum*. Applications on or before the 12th instant.
 BRINGTON, STREATHAM, AND HERNE HILL DISPENSARY—Resident House Surgeon. Salary, £150 *per annum*, with furnished apartments, attendance, coals, and gas. Applications on or before April 5th.
 CENTRAL LONDON OPHTHALMIC HOSPITAL—Assistant Surgeon. Applications on or before April 3rd.
 DOVER UNION—Medical Officer for the St. Mary's District and the Workhouse. Salary, £180 *per annum*.
 FYLDE UNION—Medical Officer of Health for the Rural Sanitary District. Salary, £50 *per annum*. Applications on or before the 5th instant.
 HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton—Two Physicians. Applications on or before the 14th instant.
 HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST—Resident Clinical Assistant. Applications on or before April 5th.
 HULL AND SCULCOATS DISPENSARY—House Surgeon. Salary, £150 *per annum*, with furnished apartments, coals, and gas. Applications not later than the 5th instant.
 LIVERPOOL ROYAL INFIRMARY—Resident Medical Officer. Salary, £100 *per annum*, with board, lodging, and washing. Applications on or before April 12th.
 MANSFIELD UNION—Medical Officer for the Fifth District. Salary, £32 10s.
 METROPOLITAN FREE HOSPITAL, Devonshire Square, City. Assistant House Surgeon. Applications on or before the 12th instant.
 MILFORD UNION, co. Donegal—Medical Officer for the Kameilton Dispensary District. Salary, £100 *per annum*, and fees.
 NEWBURY UNION—Medical Officer for the Fifth District.
 NEWMARKET UNION—Medical Officer for Nos. 1 and 3 Districts. Salary, £85 *per annum*.
 POCKLINGTON UNION—Medical Officer for the Second Pocklington District and the Workhouse. Salary, £20 and £20 *per annum*.
 POOLE UNION—Medical Officer for No. 2 District. Salary, £10 *per annum*.
 ROYAL INFIRMARY FOR WOMEN AND CHILDREN, Waterloo Bridge Road—Physician.
 SALFORD AND PENDLETON ROYAL HOSPITAL AND DISPENSARY—District Surgeon. Salary, £80, with board and lodging. Applications on or before the 7th instant.
 SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House Surgeon. Salary, £65 *per annum*, with board, lodging, and washing.
 SOLIHULL UNION—Medical Officer for the Solihull District. Salary, £44 *per annum*.
 TORREY INFIRMARY—House Surgeon. Salary, £100 *per annum*, with board and lodging.
 WESTMINSTER HOSPITAL—House Physician. Applications on or before April 5th.
 WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL—House Surgeon. Salary, £100 *per annum*, with board, washing, and furnished apartments. Applications on or before May 3rd.
 WORCESTER AND CITY LUNATIC ASYLUM, Powick—Assistant Medical Officer. Applications on or before April 5th.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication

BIRTHS.

DALY.—On March 30th, at 101, Queen's Road, Dalston, the wife of Frederick H. Daly, M.D., of a daughter.
LONG.—On March 31st, at 185, Amherst Road, Hackney, the wife of Mark Long, M.D., of a daughter.

MARRIAGES.

HOPKINS—KIRKMAN.—On March 31st, at St. Peter's, Catherington, by the Rev. W. Crotch, Vicar of the Parish, and the Rev. T. W. E. Thomas, second Master of Epsom College, Henry Cullford Hopkins, Surgeon, Bath, to Georgina Mary, youngest daughter of J. T. Kirkman, F.R.C.S., of Hordean, Hants.
LITHGOW—MURRAY.—On March 16th, at St. Jude's, South Kensington, by the Rev. R. W. Forrest, M.A., Vicar, assisted by the Rev. G. B. Pennell, M.A., Robert Alexander Douglas Lithgow, L.R.C.P.E., L.R.C.S.E., L.S.A. Lond., etc., of Wisbeach, Cambridgeshire, to Emily Mary, only daughter of Sir Robert Murray, Bart., of Hill Head, N.B., and of the late Lady Murray of Ardeleybury, Herts.
RIGDEN—FENTON.—On March 31st, at the Parish Church of St. George, Doncaster, by the Rev. Francis Pigou, Vicar, Walter Rigden, Esq., Surgeon, of Montpellier Square, London, son of George Rigden, Esq., Surgeon, Canterbury, to Cecilia Frances, third daughter of C. D. Fenton, M.D., of Doncaster.

DEATH.

*PAGET, Thomas, F.R.C.S., at Leicester, aged 72, on March 19th.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

DIXON, Hammer, M.B., appointed Assistant Medical Superintendent to the Bristol Lunatic Asylum, vice M. K. Draper, L.S.A., resigned.

THE ABUSE OF HOSPITALS: MEMORIAL TO THE COMMITTEE OF COUNCIL.

SINCE we last alluded to this subject, the following names have been added to the list of signatures:—Sir Henry Thompson; Dr. C. J. B. Williams, F.R.S.; Mr. White Cooper; Dr. Russell Reynolds, F.R.S.; Dr. Wilson Fox, F.R.S.; Mr. Samuel Lane; Mr. James Lane; Dr. Hughlings Jackson; Dr. Theodore Williams; Mr. Holthouse; Mr. Henry Arnott; Dr. Whipple; Mr. A. T. Norton; Mr. T. Bond; Dr. Potter; Dr. Norman Kerr; Mr. W. Rendall (Forest Hill); Dr. Woodhouse, J.P. (Hertford); Dr. Keblell (Brighton); Dr. Rutter (Brighton); Dr. Alfred Hall (Brighton); Dr. Seymour (Brighton); Dr. Stephens (Brighton); Mr. Beavan (Brighton); Mr. Herbert Upton (Brighton); Mr. Edward Bicknell (Coventry); Mr. McVeagh (Coventry); Mr. Fenton (Coventry); Mr. Kitchen (Manchester); Dr. Oxford (Southsea); Dr. Fiddian (Cardiff); Dr. Bacot (Blandford); Dr. T. Joyce (Cranbrook); Dr. Edwyn Andrew (Shrewsbury); Mr. Charles Solomon (Hull); Mr. S. F. Gosling (Congleton).

As it is proposed to forward the memorial to the president of the Committee of Council in a few days, gentlemen who are desirous of adding their signatures, are requested to communicate at once with Dr. Meadows, 27, George Street, Hanover Square; or with Mr. Fairlie Clarke, 12, Mansfield Street, Cavendish Square.

TESTIMONIALS.—Dr. W. M. Mackenzie of Kelso has been recently presented with a testimonial, in acknowledgment of the general appreciation of his skill, courtesy, and attention as a medical adviser, by the inhabitants of the border districts, after twenty-five years of practice among them. The testimonial was subscribed for by all classes of society, and amounted to the sum of £570. A handsome timepiece was purchased, and a cheque for the balance presented to Dr. Mackenzie. The clock bore the following inscription: "Presented to W. M. Mackenzie, Esquire, M.D., Kelso, with five hundred guineas, by his friends and patients, on the completion of his twenty-fifth year as a medical practitioner in Kelso and neighbourhood, in testimony of the high estimation in which his professional and public services during that long period are held, as well as the regard and kindly feeling entertained for him by them.—26th March, 1875."—Mr. George S. Symmons, late medical officer of the Ledbury Union, has been presented with a testimonial as a mark of the esteem in which he is held. The testimonial consisted of a purse of fifty sovereigns, and a handsome clock bearing the inscription "Presented, accompanied by a purse of £50, to George Stratten Symmons, Esq., 13 years Medical Officer of the Ledbury Union, March 18th, 1875."—Dr. Burns, the late principal medical officer of the Chatham convict prison has been presented with a handsome jug, inscribed "Presented to J. J. D. Burns, Esq., M.D., by the officers of H.M. Prison, Chatham, as a slight token of the respect and esteem with which they regard him."—The students of Anderson's University, Glasgow, have presented Dr. A. M. Buchanan, Professor of Anatomy, with an address, and a handsome ebony walking-stick with a richly chased gold head, bearing an inscription and monogram.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
WEDNESDAY ..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
THURSDAYSt. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.
FRIDAYRoyal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.
SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8 P.M. Mr. Henry Smith, a short communication "On a Case of Injury simulating Extravasation of Urine"; Mr. Lennox Brown, "Considerations on the Treatment of New Formations of a benign Character in the Larynx"; Dr. Metcalf of Geneva (by Dr. Sedgwick), "A Case of Numerous and Severe Injuries from a Fall".
TUESDAY.—Pathological Society of London, 8.30 P.M. Dr. Charlton Bastian will open a discussion on "The Germ-Theory of Disease; being a Discussion of the Relation of Bacteria and Allied Organisms to the Virulent Inflammations and to the Specific Contagious Fevers".
WEDNESDAY.—Royal Microscopical Society. Mr. H. C. Sorby, "A New Mode of Applying Spectrum-Analysis to the Microscope, etc."—Obstetrical Society of London, 8 P.M. Discussion on Puerperal Fever.
FRIDAY.—Clinical Society of London, 8.30 P.M. Dr. Buzzard will exhibit a patient with Disseminated Sclerosis. Dr. Dowse, "An Unusual Case of Lead-Poisoning"; Mr. Jonathan Hutchinson, "Case of Intracranial Aneurism, diagnosed during life, and in which spontaneous cure occurred, and the patient lived for eight years"; Dr. Hermann Weber, "Three Cases of Pyæmia, caused by Acute Suppuration of the Middle Ear, and a Case of Acute General Tuberculosis, caused by Chronic Inflammation in the same locality".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

ENGLISH PRACTITIONERS IN FRANCE.

S. P. inquires what are the restrictions, if any, that are placed on an Englishman wishing to practise as a physician in any of the maritime towns in the south of France.

* To possess a French degree is an indispensable condition to practise in France. The government is rather indulgent in that way, but the *conférences* of a country town would not, for many reasons, tolerate a practitioner who did not possess a French qualification. If the possessor of an English qualification wish to practise in France, he may, with a special permission of the Minister of Public Instruction, take the Paris M.D. by passing only the fifth examination (which is purely clinical) and the thesis. This degree may be taken also at Montpellier and at Nancy.

MEDICAL TITLES.

SIR.—Because medical men have long been called doctors by courtesy, therefore custom has established a rule, and we are now entitled to use the designation as a prefix; if this be correct, any one, because by courtesy he is addressed as Sir, in a letter or otherwise, may claim that it be written on the envelope, or print it on his cards—the only difference being that one would assume an university, and the other a court title. If Dr. Brown's motion should be carried, why should not others, following our reasoning, appropriate the title Sir, as we propose to appropriate that of Dr.?

Thanking you heartily for your advocacy in the matter of the M.D. degree, I am, yours truly,
LAM-ALPH.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

THE CASE OF THE LATE MR. MERRYWEATHER.

SIR,—Thanks to the kindness of yourself and others in giving publicity to the case of the late Mr. P. C. Merryweather, I am happy to be able to state that the total amount received by Dr. Atwood and myself already reaches £148 16s. Although to many persons this may not seem a large sum wherewith to recommence the world, it will enable Mrs. Merryweather to open a school as she proposed, and it gives her good hope and encouragement for the future. She feels very grateful for all that the medical brethren of her late husband and other friends have done for her.

Kindly insert the following list of the donations received; and should Dr. Atwood or I be favoured with any additional contributions we shall gratefully acknowledge them, for, as I mentioned in my letter to you of March 8th, we believe this to be especially a case in which help now given will be not only a temporary relief to the widow, but a permanent assistance to the whole family of a deceased medical brother.—I have the honour to be, sir, yours very faithfully,

CHARLES J. HARE, M.D. Cantab., F.R.C.P.

57, Brook Street, Grosvenor Square, March 22nd.

SIR,—Will you permit me to say a few words in support of the powerful appeal made by Dr. Hare in your JOURNAL of the 13th instant, on behalf of the wife and family of the late Mr. Merryweather? In the case of a similar appeal on behalf of the family of a deceased medical man, it was urged in derogation of their claims that there had been great improvidence; that, during her husband's lifetime, the lady and her children were the most expensively dressed persons in the neighbourhood. Having known poor Mr. Merryweather very intimately during the whole of his professional life, I can bear testimony to the fact that, both as to their personal and domestic expenditure, he and his wife were alike most careful and economical; and this not only in later years, when owing to his frequent illness his income had become reduced, but also at a time when his practice was good, and his prospects such as might fairly have justified a larger expenditure.—I am, sir, your obedient servant.

JOSEPH SEATON, M.D.

Hallford House, Sunbury, S.W., March 23rd, 1875.

ALPHA wishes to know whether the permanent prohibition from practice of resident surgeons to large special hospitals does not involve injustice to them, especially when the cases are treated by special local means, and whether it is not too commercial to be consistent with professional principle.

. The prohibition to which our correspondent refers seems to us to be not fair to those on whom it is imposed, and to savour too strongly of monopoly to be consistent with the principles which ordinarily guide the profession.

ASSOCIATE (Salisbury).—Dr. Richard C. Shettle is Local Secretary of the Reading Branch.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

DOES MALARIOUS POISON EXIST?

SIR,—In connexion with the controversy carried on in the columns of the BRITISH MEDICAL JOURNAL on the existence of malaria, denied by Dr. Inman, strongly upheld by Dr. Maclean, and supported by Dr. E. Hamilton, there are, I am sure, very many physicians and surgeons of large experience in the tropics, especially in our Eastern dependencies, who would probably have given their valuable testimony to the undoubted existence of malaria, did they not feel, with myself, that Dr. Maclean was very well able to do battle for the truth against any mere theorist, utterly inexperienced, and confessedly unqualified to judge from personal observation of the subject on which he was rash enough to write; and that Dr. Maclean's papers were quite convincing to any soberly judging man of education, who knows practically anything about the matter. But one phrase of Dr. Inman is worth considering, viz., "that until our teachers (or would-be teachers?) have a larger capacity, etc., the practice of our profession will not improve," page 8 of JOURNAL, and "if a soldier be taught that agues come from the soil," etc. Now, here is an important practical matter, and an underlying great danger; if our young men, students and medical officers, fond, it may be, as some young men are, of new lights and pseudo-scientific deductions of unwisely conducted parlour study, should unhappily receive as truth the asseverated belief of Dr. Inman "that malaria does not exist, and that ague and other so-called malarious fevers arise from a simple chill," etc., what evil practice, and what dire results to our soldiers and sailors may not arise! "Malaria does not exist," they will argue; "therefore do nothing to avoid it, laugh at all the advised precautions of the stupid old Indian doctors, keep yourself warm with a blanket or wood-smoke, and sleep when and where you please."

In face of such danger to a new generation of military and naval surgeons who might sacrifice their hecatomb of valuable lives before being convinced of their mistake, I think it incumbent on those who have the welfare of their country and its defenders at heart, to add the testimony of large and long experience to demolish such a fatal theory as that published with such confidence by Dr. Inman and the few who agree with him. I know I must be brief, but would just allude shortly to a few of the more glaring inaccuracies referred to.

1. Dr. Inman says, page 7 of the JOURNAL, "Dr. Oldham's argument is that so-called malarious diseases are due to chill after great heat," etc.; and he naively adds, "no hypothesis can be more simple." Beautiful simplicity, no doubt; so were Dr. Saugrado's theory and practice, when the world was much younger and not so wise as now. In replying to this and other fallacies, allow me to give, as shortly as possible, bold facts that cannot be controverted, and which speak for themselves. I would instance, first, the climate of Ootacamund, 7,300 feet above sea-level, where the range of temperature at certain seasons is as great, perhaps, as in any region of the globe. As senior staff medical officer at Ooty, I had charge of the meteorological instruments supplied by Government; all of the best. On a morning in March 24th, before mounting my horse at 6.15 A.M., I have marked the self-registering thermometer at 18 deg. Fah. 14 deg. of frost; on returning home the same day at 1.30 P.M., I have marked it, in the sun's rays, 182 degs.—a range of 164 degs. in a few hours—if surpassed in any other climate, sufficient at least for our purpose. Chills in Ooty, as may readily be believed, are neither few nor slight, and are destructive enough to young and old; the ordinary diseases contracted from exposure to such changes, e.g., pleurisy, pneumonia, laryngitis, and other affections of the chest and throat being of every-day occurrence. But malarious fevers of any kind, as contracted in the station, are exceedingly rare. I had some thousands of cases of disease to treat during my tenure of office, amongst them, two of continued fever following sunstroke; I never saw a case of remittent fever, except one brought from the low country for treatment in hospital. Ague, except also as imported, was unknown; the gangs of convicts under my charge, also, exposed to the burning heat of the sun as above, and to the low temperature of evening and morning, often suffering, too, from over-fatigue, got no ague, the few cases of malarious fever observed amongst all classes being in the persons of new arrivals, who had contracted the same on the ghats or in the jungles at the foot of the mountains. On the other hand, the jungly country at the foot of the hills is full of malaria—few escape it who spend much time in passing through, or who sleep at certain stations; but, mark the fact, "there is no chill" to be had there—in the hot weather, at least! One cannot even get cool unless by sitting for an hour or so in the coldest water pr curable which is constantly done with impunity in these close muggy regions. The heat, say in April, is very great, 96 deg. to 110 deg. in the shade, during day; seldom below 90 deg. in the open air at night. The air at such season is almost devoid of moisture, the earth is baked as dry as a new brick, there is absolutely no dew, the

human body is bathed in perspiration by night as well as by day; and yet these jungles teem with malarious fevers—more at some seasons than at others, but they are never absent. In my own person, exposed as I was to the great extremes of the Ooty climate, feeling my head racked by the terrible strength of the sun's rays, through the best of pith hats, with the thickest of white covers, and being chilled through substantial home clothing when returning from a night case amid the dense fog in a temperature of 12 or 14 deg. below the freezing-point, I caught several colds, was threatened with rheumatism, etc.; but, although I had suffered very often, and very much, from malarious fevers, I never had a touch of true fever while there.

Let us turn now to a very different climate, that of Labuan, lat. 5 deg. N., off the coast of Borneo. When our countrymen took formal possession of Labuan (1846, I think, was the year), our sailors, marines, and officers who landed were cut down in most alarming fashion. The first object that attracted my attention on landing in the island in 1850, was an obelisk with a portentous and melancholy list of the victims of malaria engraved thereon. These men had no chill, they did not even sleep on shore; there was no dwelling-place to sleep in, they slept in their hammocks, well protected, but with the ship anchored well in shore, in a fine bay, and they sickened with fever, and died like "rotten sheep". On my arrival I found that my predecessor, a robust, healthy man (who had built a capital house), had died shortly before of remittent fever, after about forty hours' illness. The colonial surgeon had also been in *extremis*, had been put on board ship, and a looking-glass was applied over his lips to show if he still breathed; but he fortunately recovered, as the vessel put off to sea; he also was well housed, and there was no history or suspicion of a "chill". My *locum tenens*, who had been but a short time in the island, was in bed with fever when I called to see him, and begged me to let him be carried to the steamer (which had just conveyed our party without the formality of "handing over medical charge"). He, too, was very comfortably domiciled in the house of the governor, the famous rajah Sir James Brooke; and I believe he would bear me out in saying, that he had taken all possible care to avoid cold, and other causes of illness. Clearing of the jungle, however, was then going on, with drainage of the swampy low ground adjacent to the little town which had been built; the military and the civilians of the government staff were located on well raised and dry ground about a mile from the nearest swamp; and everything was done to expel the poison emitted from the unwholesome surface. In the year preceding my arrival, the death rate in the detachment of troops was above 100 per 1,000; in the fourteen months during which I held charge of the detachment which accompanied me to Labuan, the death-rate was reduced to 30 per 1,000. The men belonged to the same regiment, were lodged in the same barracks occupied previously by their comrades, had the same rations, etc., and none of them were exposed to chills at any time; they had no heating or fatiguing labour, their only duties being light drill in the morning, and the furnishing of two or three guards. Now, about the climate of this pleasant abode. Little raised above sea-level, and very near the equator, the temperature was high, and varied little. The greatest heat in shade ever observed by me was not over 97 deg. Fahr., in an exposed verandah, equivalent to about 92 deg. in a good house; this in the month of April. The lowest minimum, at six o'clock on a January morning, was 72 deg. in the open, outside my house; but there was no such variation for the most part, these figures being the extremes of heat and cold for the whole year. The ordinary maximum was 84 deg. to 86 deg. in the hot dry weather; and 76 deg. to 80 deg. in the wet or monsoon weather; the ordinary minimum 80 deg. to 84 deg. in the two hot months (March and April); 78 deg. to 80 deg. in the others. The hottest time in the twenty-four hours was in the forenoon; the coolest in the afternoon (about 4 P.M.).—the thermometer rising, say, from 78 deg. at 4 P.M., to 83 deg. or more at night, in the hot weather; this being explained by the prevalence of the cool sea-breeze from noon to about sunset, after which the radiated heat from the sun-laked ground again raised the temperature considerably. Fevers and agues were almost the only complaints in the island during my residence, and the percentage of sickness much the same throughout the year. I think these plain facts "speak for themselves"; and I must not enlarge. I need only add here, that the few who escaped the Labuan fever of these days, did so, humanly speaking, by sleeping as high above the ground as possible (my house was raised about ten feet above drained ground; I never had fever in Labuan), and by shutting out sedulously the malarious vapours of the night.

2. Dr. Inman says, in malarious districts how can he allow that there are "malarious districts"? the temperature ranges from 140 or 150 deg. to about 50 or 45 deg. I need only remark, that the most malarious districts, evolving the most deadly fevers, have no such range, as is very well known to most Indian surgeons and others who have been much in tropical countries; but have a temperature ranging from 80 to 86 deg. minimum, to 100 or 110 deg. maximum, in the hot season, and 76 to 80 deg. minimum, to 80 or 86 deg. maximum, in the monsoons. Again, it is not those, *ceteris paribus*, who work during the day who get fever, but, as a rule, rather those who are more or less idle. Regiments of European soldiers, fond of cricket, will play throughout a whole hot season (thermometer 96 to 120 deg. in the shade, 150 to 170 deg. in sun's rays, return to barracks fatigued, and their clothes soaking with perspiration, will do little even to avoid draughts and chills in cooled rooms, and yet suffer much less from fevers and other sicknesses than their comrades who loaf about the barrack and canteen; and this is well known to all experienced officers in India.

3. "Every notoriously malarious district," says Dr. Inman, "is marshy", etc. Here Dr. Inman sadly contradicts his own previous statement, that, "at Aden, and in rocky tropical localities, fevers are as common", etc.; and he elsewhere asks, "how fevers arise where there is no water?" The truth is, there are fevers in non-marshy, as well as in marshy, places; but the important fact to bear in mind here is, "that the fevers generated in most marshy places are not bad during the rainy seasons, when the marshes are full of water, but when, after the rains, they are dried up, and no water is visible", i.e., when "the hot air is not saturated with dissolved water, and does not precipitate a 'cold dew'."

4. Dr. Inman says, "If water be precipitated, there can be no emanation", etc. How, I ask, does he undertake to prove this? Because cold air falls, does hot air not rise? Because cold vapour falls, does not warm emanations rise through such? Granting his premises, "at certain places and seasons", what then? The ground has been baked during the day, and contains much caloric; at night, the dew, if any, falls; the radiated heat (accumulated during the day) is evolved. Why should not this heat (like his "smoke" in another place) rise upwards, and carry the poison with it? How is it that, in a "notoriously malarious place", one man, who sleeps on the earth, or very near its surface, however carefully wrapped up, contracts an ague, and another man, who has slept ten feet above the surface, and no otherwise protected, escapes? No better authenticated fact than this is need be brought forward; every military or civil surgeon in India who

has been much in fever-districts will testify to its truth. The circumstances, in such instance, are the same in all other respects—the temperature high, there is no chill, no dew (or there may be both dew and chill, *n'importe*). This is an every-day occurrence in all the fever-breeding localities in India. I may remark here, as relating to Dr. Oldham's toleration of the "stinks" of the Pontine marshes (and why these "stinks", again I would ask, at night, if there be no emanations? does the dew stink?), that one such case proves nothing, unless it proves the rule. I have known individuals, here and there (one, perhaps, in five hundred), who seemed quite unsusceptible to malaria; one, now I believe in England, a colonel of Engineers, went yearly to a very malarious part of Jeypore; his men all suffered; he, never. He had no secret, except taking the usual precautions well known to Indian sportsmen and others exposed in like manner. He was a teetotaler; and, did I argue like some men who study malaria in their easy chairs, I might say "it was drinking only water that saved him". Another officer, a major of the Engineer Corps, had served in very malarious districts in China, and he had no secret, took little or no precaution, and never got fever; unfortunately for my quasi-teetotal theory, this gallant officer eschewed teetotalism.

5. Lastly, "if there be such a poison as malaria", writes Dr. Inman. Just so; there is such a poison. I do not believe there are ten educated experienced men in our whole Indian empire who doubt the fact. Then let us take care that our young medical men are taught how to protect themselves and the lives under their charge from its pernicious influence. We can and we ought to guard our men against it. And well it is that we have Netley and Dr. Maclean to teach our medical youth sound doctrine and sound practical knowledge. Even without the thousand facts which prove beyond all doubt the existence of malarious poison, it is amazing that men are to be found who, arguing in the parlour, from crude theories, on subjects of which they are practically ignorant, can educe such a belief as that a "chill" can produce genuine ague in a frame not previously exposed to the fever-poison. Are the variations of temperature almost anywhere greater or more sudden than in Scotland? Are chills unknown in that happy country? What about the thousand or so of deaths due to chills or cold alone in Glasgow during the few weeks gone by? Why were none of these deaths from agues and allied fevers? Why no cases even of these? How many physicians in Scotland can give one case of genuine home-bred ague during last year? But there is no accounting for the beliefs to which men will reconcile themselves.—I am, etc., J. DONALDSON, M.D.,

Late Surgeon-Major Medical Staff Madras Army.

A. J. MYRTLE (Harrogate).—Yes.

MEDICUS.—As no special agreement to the contrary was made, there is legally nothing to prevent A.B. from visiting patients in the manner described. But we think that—especially if there were an understanding that C.D. should succeed to the practice at the end of the partnership—it would be an honourable act on his part to abstain as much as he can from attending patients except in an official capacity.

LIBRARY would probably obtain the information which he desires by application to a medical publisher or to a vendor of second-hand medical works.

MR. G. C. COLES.—The demands on our space have prevented our making arrangements for the publication of the lectures referred to.

BOOKS, ETC., RECEIVED.

The Patent Question in 1875. By R. A. Macfie. Longmans and Co.

THE CROONIAN LECTURES ON ADDISON'S DISEASE.

Delivered at the Royal College of Physicians, London.

By E. HEADLAM GREENHOW, M.D., F.R.C.P., F.R.S.,
Physician to and Lecturer on Medicine at the Middlesex Hospital.

LECTURE III.

(Concluded from p. 440 of last number.)

NEARLY ten years ago, in a paper read before the Pathological Society, I observed that the production of the symptoms of Addison's disease by means of the implication of the nerves, was, after all, a secondary question to that of the origin of the suprarenal disease itself, of which the nerve-lesions were the consequence, not the cause. This is still my opinion; but unfortunately it is even more difficult to throw light upon the question of the etiology of the disease than upon that of its pathological processes: a difficulty owing, not only to the peculiar obscurity of the subject, but to the absence, in a majority of cases, of many of the data required in order to justify any certain conclusions being drawn from them. There are, nevertheless, some pathological conditions recorded in association with Addison's disease in so considerable a number of cases as to leave no doubt in my mind that they are not accidental complications, but have a real and more or less causal connection with the disease; and these conditions I shall now proceed to consider.

In describing the characters of the lesion in the suprarenal capsules, I have purposely avoided the use of the term "tubercular", lest I should convey an erroneous impression; but the product of the chronic inflammatory process has undoubtedly analogies with tubercle, and has been termed tuberculous, strumous, and scrofulous, more often than inflammatory. It may, indeed, be a question whether the distinction between the inflammatory and the tubercular deposits can be so clearly drawn as was formerly thought; for even the giant-cells relied on by Schüppel as decisive of the presence of tubercle are now stated by Dr. Green, in his recent *Manual of Pathology*, to be merely characteristic of chronic inflammatory processes in lymphatic structures. Be this as it may, it is impossible to resist the evidence of clinical facts as to the existence of some affinity between Addison's disease and the tubercular diathesis. By far the larger proportion of diseases of other organs found in association with Addison's disease of the suprarenal capsules are diseases of tubercular or strumous character. In the typical cases, indeed, these complications are either altogether absent, or are indicated only by small tubercular concretions in the lungs, some of which are described as cheesy, some as calcareous, others as peribronchitic nodules, and others, again, merely as indurations in the apices of the lungs. But a very considerable number of the other genuine cases of Addison's disease are complicated with more or less active tubercular disease, and, in a certain number of cases, the genuine lesion of the capsules has been found coexisting with advanced phthisis or general tuberculosis. This may be explained in two ways. Even if general tubercular disease and the particular lesion of the suprarenal capsules never stand to each other in the relation of cause and effect, it can be no matter of surprise, seeing how a vulnerable constitution, as Virchow calls it, predisposes to the development of low chronic inflammatory processes, that these two diseases should not infrequently be found in the same patient. There have been, however, a very small number of cases in which it does appear to me as if the lesion in the capsules characteristic of Addison's disease had arisen as part of a general chronic tubercular process going on at the same time in several other organs. It will be remembered that, in these cases, which were discussed in my last lecture, the characteristic symptoms and bronzing of skin were altogether undeveloped. Although this is a part of the subject on which I desire to speak with great diffidence, seeing that it can only be determined by careful *post mortem* examination of similar cases, I may say that it seems to me by no means improbable that, in these cases, secondary deposits of tubercle may have taken place in the capsules, to the extent of entirely destroying their structure, without having produced the inflammatory nerve-lesions which I regard as essential factors in the development of Addison's disease.

It is much more certain that Addison's disease of the suprarenal capsules is frequently due to extension of inflammation from diseased

or injured adjacent parts. I have records of eighteen cases in which psoas abscesses arising from caries of the lower vertebrae, and other abscesses in the vicinity of the capsules, have been followed or accompanied by Addison's disease. In several other cases, in which the spine and neighbouring parts were not examined after death, distinct tenderness on pressure was observed over two or more lower dorsal or upper lumbar vertebrae; so that I believe the number I have stated by no means represents all the cases in which this form of the disease has coexisted with inflammatory lesion in the capsules. There is clear evidence, in most of these cases, that the abscesses and vertebral disease have preceded the appearance of Addison's disease by considerable periods of time; and, in some cases, they have even become entirely quiescent for years before the development of the symptoms. A man, aged 24, who died in St. Bartholomew's Hospital under the care of Sir George Burrows, had suffered in childhood from spinal disease, and, two years before death, he had had a spinal abscess, which healed after a few months. His last illness was of eight months' duration, and, after death, the fifth and sixth dorsal vertebrae were found to be destroyed; but there was no active disease. Both the suprarenal capsules contained purulent fluid and yellowish pea-sized nodules, resembling concrete tubercular matter. In a case published by Dr. Cotton of Lynn, the patient, a member of our own profession, had suffered in the year 1847 from an abscess in the right lumbar region, which produced very serious effects upon his health; but, contrary to expectation, he recovered and remained well until 1854. His complexion then underwent a marked change, and somewhat later the constitutional symptoms of Addison's disease supervened. After several alternations of remission and exacerbation the patient died in 1857, and at the necropsy a whitish fibrous-looking obliterated sinus was found proceeding from the cicatrix of the old abscess in the right loin to the site of the structures in which the diseased capsules were firmly imbedded. The disease in the right capsule appeared to be older than that in the left.

This appears to me to be a point of so much importance in its bearing on the etiology of Addison's disease, that I will quote here two other cases exhibiting similar conditions. In the case of a deformed woman, aged 26, who was under the care of Dr. McDonogh of Clapham, and whose case is recorded by Dr. Wilks, the lower dorsal and one or two of the upper lumbar vertebrae were found to be almost destroyed; and surrounding these, adjacent to the suprarenal capsules on either side, was found a quantity of putty-like cretaceous matter—the remains of an old abscess. The capsules presented the characteristic appearances of Addison's disease in a not very advanced stage. Another case, in which an inflammatory process had apparently been the exciting cause of Addison's disease, by reason of its close proximity to the suprarenal capsules, is that of a patient of Niemeyer's, a man aged 37, whose case was diagnosed as one of Addison's disease three or four years before his death. The disease seems to have run a slow, sluggish course, complicated by successive abscesses and fistulae in various parts of the body. The constitutional symptoms and discoloration of skin were both characteristic, and he died in a sudden paroxysm of nerve-paralysis. The capsules were found in the usual conditions, the right one still showing a trace of normal structure, and both were imbedded in much firm tissue. The left capsule and kidney were blended together into one mass with the neighbouring portion of the descending colon by means of a firm tissue traversed by strong fibrous threads. The colon at this part was the seat of an extensive cicatrix of an old ulcer, which had involved the whole tube, and had much contracted it by the thickening of its walls. The colon was adherent to the pancreas by the same mass of hard tissue which bound it to the left suprarenal capsule.

In some of these eighteen cases, the disease which seems to have been the exciting cause of the inflammatory process in the suprarenal capsules, has apparently been due to constitutional tendencies; but, in several of them, there is a distinct history of injury which has obviously produced it, and in apparently healthy subjects. The most striking case of this kind which has come under my own observation is that of a coal-porter, aged 32, who was admitted into the Middlesex Hospital in the year 1866 under Dr. Stewart's care. His health had been robust until about three years before his death, when he suffered a severe strain in the back from pushing a loaded coal-truck, and felt a sensation as of something giving way. From that time, he felt more or less pain in the loins; but the first symptoms of Addison's disease supervened only ten months before his death, or two years after the accident. The case was, like most of those in the class I am discussing, a typical one as regards the constitutional symptoms and the bronzing. At the *post mortem* examination, the suprarenal capsules were both found imbedded in thick fibrous tissue, and adherent to the surrounding parts. The right capsule was much enlarged and nodulated, consisting of semitransparent tissue, yellow cheesy masses, and

small calcareous patches; the left capsule was smaller, and contained more calcareous matter. Adjacent to the capsules, and in front of the lower dorsal and upper lumbar vertebrae, was a largish abscess, bounded by firm fibrous investments. Lastly, on examination of the spine, the intervertebral substance between the lowest dorsal and the first lumbar vertebra was found to be separated from the upper surface of the last-named vertebra, for two-thirds of its depth, on the left side, but the separation did not extend to the spinal canal. The denuded surface of the upper lumbar vertebra was rough and carious. The clinical history and pathological conditions, in this case, scarcely leave room for doubt that the separation of the intervertebral substance took place at the moment of the strain three years before death; and that this injury gave rise, primarily, to the abscess in front of the injured parts; and secondarily, by extension of inflammation from the abscess, to the disease in the suprarenal capsules.

Another remarkable case of the same character is recorded by Dr. Grey Glover in the *Edinburgh Medical Journal* for 1859. The patient, a furnace-man at some chemical works, had hurt his back by a fall. Three years later, he became of a yellow colour, and was supposed to be jaundiced. Notwithstanding medical treatment, the discoloration never left him, and it ultimately deepened into the typical bronzing of Addison's disease. The peculiar constitutional symptoms only began to develop three years after the first appearance of the discoloration, and the patient died after two years' illness. The capsules were entirely destroyed, and consisted of a semi-transparent deposit, with some opaque white material and cretaceous masses; and in this case also there was psoas abscess, with caries of the two lower dorsal and upper lumbar vertebrae. Dr. Wilks, to whom the capsules were sent for examination, pronounced the case to be a capital example of Addison's disease; and, in referring to it in one of his papers in the *Gay's Hospital Reports*, he stated that the fact of caries of the spine being the only disease which had in two or three cases been found preceding Addison's disease, strongly suggested the opinion that the capsules might have been secondarily affected by it.

In ten or twelve other cases, abscesses, frequently connected with disease of bones, or otherwise apparently of scrofulous character, have been found in situations more or less remote from the diseased suprarenal capsules. In several of these, as in many of the cases complicated with tubercle of the lungs, the only connection between the two diseases has probably been the constitutional vice which predisposed to the development of both of them; but in others, in which the local seats of inflammation were not far removed from the suprarenal capsules, the disease probably spread, as in Dr. Cotton's case, by continuity of tissues, although the connection was overlooked at the *post mortem* examination. In a case of my own, that of a man aged 24, who died at the Middlesex Hospital in the year 1864, there had been an abscess in the left hypochondrium about nine months previous to his death. Soon after it healed, he had been attacked with severe pain in the left hip, which never left him. Typical symptoms and discoloration of skin supervened, and he died in a few months of Addison's disease. The capsules exhibited the usual characteristic changes; and a small abscess was found situated underneath the pelvic fascia, containing about half an ounce of pus, and directly communicating with carious bone at the left sacro-iliac synchondrosis. I am now of opinion, from analogy with other cases, that I overlooked a connection between this abscess and the tissues adjacent to the suprarenal capsules. At least, it is certain that, not fully appreciating at that time the important bearings of such a connection, I made no sufficient search for it.

I must now invite your attention to a class of cases in which there is no pathological evidence of the existence of any local lesion from which there could have been an extension of inflammation to the suprarenal capsules, but in which, nevertheless, the clinical history of each case very decidedly points to some severe strain, or blow, or physical shock, usually in the back, as the starting-point of the illness. Unfortunately, the previous history is wanting in so large a proportion of cases, that I can only quote seven unproved cases of this class. A woman aged 31, who died under my care in 1858, when I was Physician to the Western General Dispensary, constantly assured me that she had never recovered from a strain in the back received in turning a mangle some years before her last illness. A female servant aged 30, who died in the Middlesex Hospital under the care of Dr. Burdon Sanderson, was laid up for a week with pain in her back from a fall down stairs, and began to fail in health from that time. In like manner, a druggist's assistant, aged 16, fell through a trap-door; and, although Dr. Bristowe, whose patient he was, verified the absence of any disease of the bones of the spine or pelvis, the lad's illness undoubtedly dated from the fall, which he survived sixteen months. Lastly—for it would be tedious to enumerate all these cases—a German factory-manager, whose case is related by Dr. Ploss, dated his illness

from supposed rheumatic pains occasioned by a fall over a bank two years before death. These seven cases were all typical, in the sense of there being no coexisting disease of any importance; but in almost all of them some tubercles are reported in the apices of the lungs, giving evidence of the existence of a tubercular diathesis, with which Addison's disease appears to have so strong an affinity, and which may have predisposed these persons to its development from slighter or more temporary causes than would have given rise to it in persons of different constitution.

In four or five cases, patients have referred their illness to physical over-exertion; in about the same number of cases, to nervous shocks, grief, or anxiety; and in two or three cases, to attacks of intermittent fever. The evidence in such cases is, of course, somewhat vague and questionable; and, due regard being had both to the apparent inadequacy of the supposed causes, and to the occasional latent course of the disease until its symptoms are developed under some external depressing influence, it may fairly be conjectured that, in most of these cases, the lesion of the suprarenal capsules existed antecedently to the supposed cause of illness, which was only the immediate exciting cause of the manifestation of the symptoms. It is well not to overlook any aspect of so obscure a subject; and, therefore, without attaching any undue importance to the alleged facts in the history of these cases, I think it advisable to keep them in view.

There still remain, however, a majority of the whole number of cases, in which neither the clinical history nor the pathological conditions seem to afford any clue to the origin of the disease. In too many cases, indeed, these are imperfectly reported or altogether wanting; but in many others, in which they are recorded, we find no trace of any antecedent cause. Good health until the apparently causeless beginning of the fatal illness is perhaps the most frequent history; and in typical cases, the usual report is, that all other organs were healthy; the exceptions to this rule being, as I have said, the presence of small inactive tubercular deposits in the lungs.

In this absence of all internal conditions, and of all direct evidence of external injuries, which might serve to refer the origin of Addison's disease, in these cases, to any of those causes which have apparently been its starting-point in the cases belonging to the other classes with which I have dealt, we must fall back upon the indirect information to be derived from the very obvious influence of sex, age, and occupation, upon the development of the disease.

Taking the 183 cases which I classed as unequivocal examples of Addison's disease, I find, as regards sex, that in 119 of these cases the patients were of the male sex, whilst in 64 they were females.

As regards age, my analysis shows that by far the larger number of the sufferers were persons in the most active period of adult life. Of the 119 males, 92 died between the ages of twenty and fifty; whilst nineteen boys died under the age of twenty, and eight men over the age of fifty. The two youngest boys were aged eleven and thirteen years respectively, and the oldest man was fifty-eight years of age. Again, of the 64 females, 47 died between the ages of twenty and fifty; ten girls under the age of twenty, and seven women over the age of fifty. The two youngest girls were also aged eleven and thirteen years, and all the seven older women were under sixty, except one, who is stated to have reached the age of sixty-nine.

If we now look to the rank in life, and the occupation of the sufferers, we perceive that more than nine-tenths of the whole number have belonged to those classes which are engaged throughout the active period of life in physically laborious work. Only eight or nine of the male patients have belonged to the classes of gentry, professional men, or merchants, whilst not more than six of the females have been in the position of ladies.

With respect to the occupations of the men, and still more those of the women, the data are very deficient; but the fact that they were apparently almost all in the class of hospital patients speaks for itself as to the probability of their having led a life of active manual labour in some form or other. Of the eighty-five men belonging to the working classes whose occupations are recorded, fifty-one were employed as agricultural labourers, porters, stonemasons, bricklayers, coal-miners, or in similar heavy work; a considerable number were costermongers, hawkers, journeymen-tailors, shoemakers, etc., whilst a few were publicans, shopkeepers, clerks, or had other miscellaneous occupations. With respect to the large majority of women of the working class, we have no information beyond their age. Of the sixty-four female patients, ten are stated to have been servants, maids of all work, laundry-maids, or cooks, six needlewomen, and three out-door labourers. Some, and in all probability very many, of the others, were poor married women, and on no other class of their sex, perhaps, rests a heavier burden of labour.

Lastly, with respect to the extreme rarity of the disease in persons

exempt from the necessity of bodily labour, I may quote my own experience. Although seven or eight cases have been referred to me in private practice, as supposed cases of Addison's disease, only two of these have been true cases of the disease, and I have met with no others amongst persons of the middle and higher classes. I believe, too, that in this respect, the experience of all other physicians will be found to coincide with mine.

From these data, therefore, imperfect as they are, the following deductions may safely be drawn.

The occurrence of Addison's disease takes place almost exclusively in persons employed in active manual labour.

The mortality caused by it is pretty equally distributed over the laborious period of life, and to that period it is almost entirely confined.

The disease is comparatively much more frequent in persons of the male sex, whose employment naturally involves the heaviest kinds of labour.

Lastly, a preponderating number of the cases which occur in persons of the male sex are found amongst those classes of labourers whose occupations are most likely to expose them to bodily injury from accident or over-exertion.

The facts thus brought out cannot fail to suggest obvious inferences as to the probability that, in many of these cases, more or less temporary causes of local inflammation may have existed, similar to those which appear to have been the starting point of the disease in some of the cases to which I have specially referred. In persons of the working classes, strains and falls, which do not involve disabling consequences, are soon forgotten, and therefore seldom reported; whilst the necessity of striving against the weakness induced by a strain or blow may tend to keep up an inflammatory process, which would have naturally subsided under favourable conditions of rest. Without, therefore, venturing to speak dogmatically on a point which can only be cleared up by much future investigation, I may yet say that I incline to believe the origin of Addison's disease, in many of the unexplained cases, to be due to traumatic causes, although its development has probably been favoured by certain constitutional proclivities.

Very few words need be said here with respect to the diagnosis and prognosis of Addison's disease. The diagnosis is founded upon the constitutional symptoms, aided, in a large majority of cases, by the presence of more or less of the peculiar change of colour in the skin. It is not always unattended with difficulty, but, to those who have any practical acquaintance with the disease, it is not, I think, more doubtful than the diagnosis of many other chronic diseases. The prognosis is, of course, invariably grave as regards the ultimate result, though it is impossible to say to what extent life may be prolonged under favourable circumstances. Rest and scrupulous avoidance of bodily or mental excitement, or any other causes of nervous exhaustion, form the essential parts of the therapeutical management of all such cases; whilst the diet and medical treatment must be carefully adapted to the inevitably varying phases of the disease.

It only remains for me to sum up, in conclusion, the objects which I have had in view in the course of lectures which I have had the honour to deliver before you.

In the first, I believe I delineated faithfully all the principal clinical symptoms of Addison's disease, and the remarkable varieties in their course; together with the true characters of the pathological lesions in and around the suprarenal capsules, which have been found to coexist with them.

In the second lecture, I endeavoured to show clearly, on the one hand, the concurrent testimony of facts in proof of the real connection subsisting between these clinical symptoms and the one specific lesion in the suprarenal capsules, and, on the other, the baseless nature of the misconceptions which have prevented the general recognition of its reality.

In to-day's lecture, I have trodden on more difficult ground. No one can feel more strongly than myself that the opinions which I have been led to form, with respect to the obscure pathological and etiological processes in Addison's disease, rest as yet upon an inadequate basis. I can only express the hope that, however problematical their correctness may appear to many, the suggestions I have ventured to make, regarding the probable mode of production of the symptoms of Addison's disease, and the probable means of origin of the suprarenal disease itself, may lead to a thorough investigation, in future cases, of all the facts bearing upon these questions; and thus, to the acquisition of knowledge which may justify positive conclusions, in place of the uncertain inferences which are all that I have been able to draw, from my own necessarily limited personal experience, and the insufficient materials at my command.

THE GERM-THEORY OF DISEASE:

BEING A DISCUSSION OF THE RELATION OF BACTERIA AND ALLIED ORGANISMS TO VIRULENT INFLAMMATIONS AND SPECIFIC CONTAGIOUS FEVERS.

By H. CHARLTON BASTIAN, M.D., F.R.S.,

Professor of Pathological Anatomy in University College, and Physician to University College Hospital.*

WHEN honoured by a request from the Council of this Society, a few weeks since, to open a debate during the current session, compliance with such a wish was regarded by me as a professional duty. I was compelled, therefore, to do the best I could with the short time and limited leisure which presented themselves, though these, I regret to say, have proved insufficient to enable me to bestow the attention I should have desired upon the vast accumulation of writings directly or indirectly related to the subject selected for discussion, and quite insufficient also to enable me to throw light upon it, to the extent I should have wished, by certain new observations of my own. The subject, however, large as it is—and consequently difficult to be dealt with satisfactorily in the space of one hour—seemed to recommend itself for several reasons. (1) It is a question lying at the root of the pathology of the most important and most fatal class of diseases to which the human race is liable—diseases which cause nearly one-fourth of the total number of deaths in this country. (2) It is a subject important alike to those engaged in almost every department of our profession. And (3) it is one which I happen to have very carefully considered for several years, and for the elucidation of which I was tempted in 1869 to undertake long and laborious investigations, though these may have seemed to many to have little practical bearing upon the science of medicine.

The subject of the relation of the lower organisms to disease has, moreover, a growing importance. The notion that there is a distinct causal relation between the two—though it has long existed in one form or another—is one which has been spread enormously within the last few years, partly owing to our increase of knowledge concerning these low organisms, and partly because of their ascertained presence in numerous diseased tissues and exudations. Medical literature, both at home and abroad, now in fact teems with papers and memoirs bearing upon this relation, and such communications rapidly increase in number yearly.

In the short time allotted to me to open the debate, I shall be able to make specific allusions to but few of these contributions, as it would seem better to keep the broad issues well in view in my opening statement, and to reserve questions of detail, as these may be taken up by other speakers and subsequently commented upon where necessary.

The one common and distinguishing feature peculiar to all the diseases, whose pathology we are now about to consider, is their "contagiousness". An individual affected by either of them throws off particles from the region specially affected, or from many parts of the body; and these particles, on coming into contact with suitable surfaces in other persons, may incite similar local or general diseases—though such results do not invariably follow. This peculiarity, by means of which such diseases are spread amongst the members of a community, was, even in the time of Hippocrates, compared to the property by which one fermenting mass may communicate its state of change to another mass of fermentable material. Throughout all intervening periods such an analogy has never been lost sight of—it has rather been more and more strongly dwelt upon. Thus, more than two centuries ago, we find, as has been recently pointed out, Robert Boyle, one of our great English philosophers, and himself a pioneer in scientific investigation, giving strong expression to the then current view. "He that thoroughly understands", he says, "the nature of ferments and fermentations, shall probably be much better able than he that ignores them, to give a fair account of several diseases (as well fevers as others) which will perhaps he never thoroughly understood without an insight into the doctrine of fermentation." Again, in more recent times, it was doubtless under the influence of a belief in the same analogy between fermentations and the class of diseases of which I am about to speak, that the term "zymotic" was proposed by Dr. Wm. Farr, and adopted as a general designation, under which nearly all these diseases might be included. The consequence of the adoption of this nomenclature has been, that views as to the nature of the infecting something or *contagium* have since been so powerfully influenced as to

* Read before the Pathological Society of London, April 6th.

be actually led by views at the time entertained concerning the nature of *ferments*. The relationship supposed to exist between zymosis and fermentation has indeed been stamped and ratified by the very general consent of the profession.

Omitting for the present any remarks as to the real strength of this analogy, I would merely further point out that the foundations of the "germ-theory of disease", in its most commonly accepted form, were laid in 1836 and shortly afterwards. The discovery at this time of the yeast-plant by Schwann and Cagnard-Labour soon led to the more general recognition of the almost constant association of certain low organisms with the different kinds of fermentations. But it was not till twenty years afterwards that Pasteur announced, as the result of his apparently conclusive researches, that low organisms acted as the invariable causes of fermentations and putrefactions—that these, in fact, though chemical processes, were only capable of being initiated by the agency of living units. If, in accordance with this somewhat narrow and exclusive view, living units were to be regarded as the sole producers of fermentation and putrefaction, then they were the sole ferments. The extension of this doctrine by medical men to contagious diseases, in face of the analogy sanctioned by the use of the term "zymotic", became only too easy. It was obviously nothing but the logical outcome of the two sets of views, to hold that low organisms were the true contagia or sole "germs" of the so-called zymotic diseases.

It so happens, therefore, that the very exclusive notion just mentioned, as to the nature of contagia, is at present almost as deeply rooted in the minds of the majority of writers on epidemic diseases and contagious fevers as was the opposite notion, founded upon the physico-chemical doctrine of Liebig some twenty years ago. Then a ferment was regarded as a portion of organic matter (not necessarily living) in a state of molecular change ("motor decay"), which, by virtue of its own unstable nature, was capable of communicating molecular movement (chemical change) to other unstable or fermentable mixtures. This broader notion was promulgated by Liebig, at a time when less was known than at present as to the constant association of low organisms with the processes of fermentation and putrefaction. The nature of this relationship was, in fact, never adequately grappled with by him. Still, views of this kind, promulgated by Liebig, would not give anything like the same support to the germ-theory of disease as that afforded by the doctrines of Pasteur. Those who have adopted and developed Liebig's views now hold that living organisms, though they may operate as ferments, act in this capacity merely by virtue of the chemical changes which the carrying on of their growth necessitates; and that other chemical changes, taking place during the decay of organic matter, may make fragments of it (in the dead state) almost equally capable of initiating fermentative changes in suitable media, whilst in either case bacteria or allied organisms are prone to be engendered as correlative products.

In the present day, therefore, two questions seem to need the serious consideration of medical men. In the first place, it may be asked, Are we justified in relying so strongly upon the analogy between fermentation and zymosis? Secondly, we may inquire whether the researches by which Pasteur claims to have established the sole nature of ferments are so conclusive as they have been commonly regarded. In reply to the first question, certain qualifying considerations will hereafter be stated, though it may be at once admitted that the analogy is so strong as to make it likely to continue to exercise a very considerable influence upon medical opinion. It therefore becomes all the more necessary for medical men to look to the foundations of Pasteur's doctrine, if they are not prepared blindly to follow his dicta on a subject which is of so much importance for medical science. It was with this view that I undertook a few years ago, and shortly after I had been called upon to teach pathology, a series of investigations bearing upon this subject. In consequence of this work, I was compelled, as others had been, to refuse assent to the exclusive doctrines of Pasteur concerning the nature of ferments. I do not enter upon this discussion now. I maintain, however, that my own investigations and those of others show that units of living matter are not the sole ferments, since fermentation and putrefaction may be initiated in their absence, and since it can be shown that mere particles or fragments of organic matter may act in this capacity. For a brief exposition of the grounds of this belief, I would refer those interested in the matter to my recently published work, *Evolution and the Origin of Life*.

Some time must be allowed to elapse before anything approaching to general agreement can be expected on such a subject; and, meanwhile, standing as we do in the face of opposite doctrines as the nature of ferments, we are free to look into the question of the relation of the lower organisms to disease on its own merits—apart, that is, from the overweighing influence of any general theory of fermentation.

Leaving on one side, therefore, the influence of the analogy deemed

to exist between the process of fermentation and that of zymosis, we may ask what other general evidence is forthcoming in favour of the notion that contagia are low organisms or living units, rather than dead organic particles from altered tissue-elements, or complex chemical compounds of alkaloidal constitution engendered in the tissues or in some of the fluids of the body. The consideration of this question may be introduced by a quotation from Dr. Burdon Sanderson's valuable report on the "Intimate Pathology of Contagion" (Twelfth Report of the Medical Officer of the Privy Council, 1870, p. 243). He says: "There are two obvious objections which stand in the way of the acceptance of any chemical explanation of the phenomena of contagion. The first is, that the multiplication of contagium in the body of the infected individual is a process which cannot be compared to any which is brought about by chemical agencies independently of organic development. The second is, that all contagia possess the power of retaining their latent virulence for long periods (often resisting the most unfavourable chemical and physical conditions), and only show themselves to be what they are when they are brought into contact with [the] living organism. Outside of the body, the contagious material withstands all those changes to which, on chemical grounds, we should expect it to be liable; while in the body it manifests a degree of activity, and gives rise to an amount of molecular disturbance, which is quite as unaccountable.....Neither of these difficulties stands in our way if we suppose that the contagious process is connected with the unfolding of organic forms."

Now, although this is about as strong a statement as can be made, from an *à priori* point of view, against the mere chemical action of contagium and in favour of a germ-theory, I must confess that neither of the considerations seems to me to carry very much weight with it. I should be inclined to say, in reply (1), that proof is altogether wanting of the "multiplication of contagium" in the body in the same sense that a living unit multiplies; and that there are physico-chemical processes which may illustrate what occurs when contagium increases within the system. Instead of an increase by continuous organic development and multiplication, it may be that contagium augments by some such process as that by which crystals of sulphate of soda increase or "multiply" when a fragment of such a body is thrown into a complex fluid containing its component elements. This is confessedly a very imperfect illustration, and one to which I resort merely to indicate the possible occurrence of another mode of increase of contagium within the body; though, in an infected animal, such increase may occur in a much more subtle manner, owing to the fact that fluids altered, directly or indirectly, by the original contact of contagium with some part of the body, are either locally or generally brought into intimate relation with the active, though modifiable, living units of the various tissues. And (2), in reply to Dr. Sanderson's other objection, which stands, as he supposes, in the way of any chemical explanation of the phenomena of contagion, I should say that, although our knowledge is at present extremely vague concerning the power possessed by the various contagia of retaining their virulence for long periods, and of resisting unfavourable physical and chemical conditions, we have no reason to believe that the more complex combinations of which living matter is composed are capable of resisting influences which would prove destructive to less highly complex not-living substances—such as snake-poison, woorara, or other compounds of this class. The general evidence is, therefore, as I read it, certainly not more favourable to a vital or germ theory than to a physico-chemical theory, as regards the nature and action of contagia.

I should here point out, however, that under the term "germ-theory" two distinct views are included, each having its advocates amongst distinguished members of this Society. The side to which Dr. Sanderson leans is sufficiently obvious. Speaking of contagious particles, he says (*loc. cit.*, p. 255): "With reference to their mode of action, we have examined into those considerations which seem to render it probable that they are *organised beings, and that their powers of producing disease are due to their organic development*; and we have accepted this doctrine as the only one which affords a satisfactory explanation of the facts of infection."

This is the doctrine with which we are at present especially concerned, though it may be well for me to say a few words concerning the other sense in which a "germ-theory of disease" is maintained by a distinguished member of this Society. Dr. Beale says (*Disease-Germs, their Real Nature*, 1870, p. 5): "We have, therefore, now to inquire what is the material substance which passes from the diseased to the

* These words occur in a summary which, it is only right to add, was immediately prefaced by the following statement. "The sentences which follow must therefore be accepted by the reader as nothing more than indications of the questions we are trying to solve, or as forecasts of what we hope to establish or disprove by experiment."

healthy organism in small-pox, in measles, in scarlet fever, and other allied contagious diseases from which man and domestic animals suffer so severely. *The material in question grows and multiplies and produces its kind, as all living things do, and as nothing that does not live has been proved to be capable of doing.* We may, therefore, conclude that it is living matter." And, as to the derivation of such matter, Dr. Beale says, "a disease-germ is probably a particle of living matter derived by direct descent from the living matter of man's organism", though he supposes it to be altered and degraded as regards formative power by previous rapid multiplication of the tissue-elements or particles from which it has been derived. In many respects, I am disposed to assent to this view, so long as it is not taken in too exclusive a sense. I will now, however, only mention what I consider to be its weakness. It seems to me that proof is wholly wanting as regards the statement which I have had printed in italics. That there is an enormous increase of germinal particles in the blood and in many of the tissues in these specific contagious diseases, Dr. Beale has helped to show us by his valuable researches upon the pathology of the cattle-plague and other allied affections; but that such germinal or living particles are in any direct sense the descendants of the particles which act as contagia, or, in fact, that the contagious particles really multiply to any extent in the body—these are propositions which at present appear to me to be wholly devoid of all proof. I and other pathologists are free to hold that contagious particles, whether composed of living or of not-living organic materials, may initiate changes in the tissues and fluids with which they come into contact, which changes may be exaggerated as they spread, so as at last to implicate the blood. And, as one result of this altered constitution of the nutritive fluid and of the general febrile condition simultaneously excited, we may get that undue proliferation of tissue-elements and multiplication of their products which appear to go on in the blood and in the various tissues of persons suffering from these febrile diseases.

Leaving this aspect of the question, therefore, I now turn to the special subject of this debate—viz., the truth of the germ theory, as it is ordinarily understood, or the relation of the lower organisms to virulent inflammations and their sequelæ on the one hand, and to specific contagious fevers on the other.

Applicability of the Germ-Theory to Virulent Inflammations and their Sequelæ (Gonorrhœa, Purulent Ophthalmia, Erysipelas, Hospital Gangrene, Puerperal Fever, Pyæmia, Septicæmia, &c.)—A few years ago, no one would have thought of connecting the contagiousness of gonorrhœa or purulent ophthalmia with the presence of bacteria. The respective secretions were known to contain some poisonous element either in the form of a chemical compound or altered product of tissue-multiplication (pus), which, when it came into contact with a healthy mucous membrane, was capable of acting as a specific irritant, and there exciting a similar morbid process. It is by no means certain, however, that some pathologists would not, at the present time, connect this process with the presence of bacteria in the contagious fluids. Such a point of view has, indeed, been directly fostered by doctrines recently put forward by an eminent pathologist—Dr. Burdon Sanderson. At this Society, in 1871, whilst, strangely enough, professing to be indifferent to the mode of origin of bacteria, Dr. Sanderson said: "They afford a characteristic by which we may distinguish the products of infective inflammation from those which are not infective." And in a more recent paper on "The Infective Product of Acute Inflammation" (*Medico-Chirur. Trans.*, 1873, p. 354), referring to his previous researches, he says it was inferred from these that, "if infective agents are particulate, they are probably comprised in that group of bodies to which I then applied the term micrococci, recognising their identity with the *zooglaa* of Cohn, the *micrococci* of Hallier, and the various forms described by other authors under the terms *bacterium* and *vibrio*". And he then adds, as the result of subsequent investigations, the following passage: "With reference to these organisms, two entirely new and most important facts have been demonstrated by the observations to be now recorded. It has been discovered (1) that, in all acute infective inflammations, micrococci abound in the exudation liquids; and (2) that the same forms are to be found in the blood of the infected animals". And, when Dr. Sanderson subsequently adds "that the relation of intensity between different cases of septicæmia and pyæmic infection is indicated by the number and character of these organisms", but little doubt seems to remain concerning his views as to the causal relationship of such organisms to the infectiousness of the inflammations referred to. And this view is not essentially modified by his subsequent concluding explanations, where he says: "Inasmuch as these organisms cannot have originated from the external normal tissues or juices, they must have been derived from the moisture." And, also, "It does not at all follow because these organisms come in from outside, that they bring contagium along with

them; for it may be readily admitted that they may serve as carriers of infection from diseased to healthy parts, or from diseased to healthy individuals, and yet be utterly devoid of any power of themselves originating the contagium they convey." Such a doctrine still implies that bacteria are essential to a contagious process, though it seems to me to introduce certain very striking elements of weakness into the germ-theory as thus interpreted. If this theory is not tenable, without the aid of some supplementary hypothesis, I cannot conceive that the introduction of the one above mentioned will be considered to have strengthened its foundations. Yet Dr. Sanderson apparently saw the difficulty of maintaining the germ-theory in its integrity, and offered us this other view as a compromise. He considers it probable that, whereas true contagia, whether living particles or chemical compounds, may be engendered within the body in the tissues themselves, such contagia are not able to spread either within or outside without the aid of bacteria to act as "carriers". But why one set of particles should need others to carry them, or why bacteria alone should be able to bear about these mysterious contagious poisons which they are devoid of the power of originating, does not at all appear!

However complicated the doctrine may have been rendered, this is still practically the germ-theory; and the same thing may be said with reference to a view which Professor Lister seems to entertain with some favour. He thinks that the lower fungi, and their relations bacteria, may contain in themselves some chemical compound absolutely peculiar to them, and forming part of their substance, which may act upon albuminous compounds after the manner of a ferment, such as emulsin (*Nature*, July 17th, 1873). "In this sense", he thinks, "as intervening between the growth of the organisms and the resulting decompositions, the theory of chemical ferments might be welcomed as a valuable hypothesis." This seems like the language of concession, but, practically, it is the germ-theory still, and expressed too much as all germ-theorists who think out their views would have to formulate them. It would be no great concession to those who are not believers in an exclusive germ-theory if, in the light of his views, as above expressed, Professor Lister were to say that bacteria were "carriers of infection"; yet the apparent concession above referred to is no more of a concession to believers in a physico-chemical theory than the latter admission would be.

I will, however, now briefly enumerate the evidence which seems to me quite sufficient to disprove the probability of the existence of any causal relationship between the lower organisms and the diseases cited at the head of this section, and to establish, on the other hand, the position that the bacteria met with in diseased fluids and tissues are, for the most part, actual pathological products—that they are, in fact, engendered within the body, or are descendants of organisms owning such an origin, rather than of previously existing organisms introduced from without. It would take far too long were I to attempt to enter at any length upon a consideration of this evidence. I must, therefore, content myself with briefly summarising the principal facts and arguments on which a judgment may be founded.

1. The experiments of many investigators prove that the alleged causes of disease may be actually introduced into the blood-vessels of lower animals by thousands without producing any deleterious effects in a large proportion of the cases.

2. Bacteria, if not actually to be found within the blood-vessels of healthy persons, do nevertheless habitually exist in so many parts of the body in every human being, and in so many of the lower animals, as to make it almost inconceivable that these organisms can be causes of disease. In support of this statement I have only to say, that even in healthy persons they may be found in myriads in and about the epithelium of the whole alimentary tract from mouth to anus; they exist throughout the air-passages, and may be found in mucus coming from the nasal cavities, as well as in that from minute bronchi. They exist abundantly amongst the epithelial *alveoli* within the ducts of the skin, not only in the face, but in other parts of the body. Fresh legions of them are also being introduced into the alimentary canal with almost every meal that is taken, whence they may perhaps readily find their way into the mesenteric glands, if not further within the system. And lastly, in persons with open wounds, bacteria are constantly to be found in contact with such surfaces, especially if the wounds be not well cared for, though the injured person does not necessarily suffer at all in general health.

3. It is no answer to these difficulties to say that there are distinct species amongst these lower organisms, some of which are harmless, though others are poisonous (or so-called "germs" of disease). In support of such opinion, nothing can be alleged save some of the facts whose cause is doubtful; whilst against such an interpretation may be brought the experiments of several investigators, showing that bacteria are the creatures of circumstance, and modifiable to an extraordinary

degree. The last position is even admitted by Professors Sanderson and Lister. The former acknowledges that they are "the lowest organisms," and that they are "much more under the influence of the conditions under which they originate and are developed than organisms of any other class", whilst Professor Lister's own work has compelled him to make an admission which, in the face of facts previously stated concerning the wide distribution of bacteria within the body, seems fatal to a consistent belief in the germ-theory of disease. He says: "If the same bacterium may, as a result of varied circumstances, produce in one and the same medium fermentative changes differing so widely from each other as the formation of lactic acid and that of black pigment in milk, it becomes readily conceivable that the same organism which under ordinary circumstances may be comparatively harmless, may at other times generate products poisonous to the human economy."—(*Quart. Jour. of Microscop. Science*, October 1873.)

4. The consideration now to be mentioned suffices, in my opinion, to complete the discomfiture of the germ-theory as an explanation of the mode of causation of the diseases with which we are at present concerned. It is this. It has been shown, on the one hand, that the virulence of certain contagious mixtures diminishes in direct proportion to the increase of bacteria therein; and on the other hand, it has been equally proved that fresh and actively contagious menstria lose scarcely any of their contagious or poisonous properties after they have been subjected for a few minutes, when in the moist state, to a temperature which no living units can be shown to survive (212 deg. F.), or after they have been exposed to the influence of boiling alcohol, which is well known to be equally destructive to all recognised forms of living matter. Such facts have been substantiated by Messrs. Lewis and Cunningham, Sanderson, and others.

Having said thus much in opposition to the germ-theory, let me as briefly enumerate the facts and arguments which seem to me to show the real relations of bacteria and their allies to the diseases in question. I turn, therefore, to the construction of an opposite doctrine.

Admitting in part the very frequent presence of bacteria in diseased fluids and tissues, I consider that their presence and import should be differently explained. I say I admit the association in part, though I by no means admit it to the extent alleged. Bacteria are not, for instance, to be found in the blood of persons suffering from pyæmia, as might be inferred from former statements of Dr. Sanderson, which I have already quoted. My own experience in this matter seems to be entirely in accordance with that of Professors Billroth and Stricker. Neither do I believe that the presence of bacteria in inflammatory fluids has the significance which Dr. Sanderson attaches to it, since it has been ascertained by myself and others that the exudation-fluids of sick persons suffering from diseases of a totally different type, are often similarly crowded with these lowest organisms; whilst the recent observations of M. Bergeron (*Compt. Rend.*, February 1875) seem to show that they may be found even in freshly extracted pus from ordinary abscesses occurring in elderly persons.

Now, it would seem quite obvious, that the consistent advocate of a germ theory of disease can only successfully maintain such a doctrine if he can show, amongst other things, that bacteria are more capable of altering the characters and chemical constitution of fluids of the body than they are themselves prone to be altered by independently initiated changes taking place in such fluids. It seems, therefore, like unintentionally cutting himself free from the theory to which he has hitherto adhered, when we find Professor Lister, in speaking of the assumed "special virus of hospital gangrene", going on to say that "it is not essential to assume the existence of a special virus at all, but that organisms common to all the sores in the ward may, for aught we know, assume specific properties in the discharges long putrefying under the dressings". This passage has a similar import to that of a quotation previously made. In both, a first place is assigned to the modifying influence of altered fluids; and, however much the correctness of such a supposition would tell in favour of cleanliness, of free exposure, or even of anti-septic dressings, it is none the less inimical to a consistent holding of the theory on which Professor Lister has chosen to base his system of treatment.

But, though such statements are adverse to the holding of a germ-theory in the only form in which it may be at all tenable, they are entirely in accordance with my own observations and views. I maintain, in short, that even the very existence of organisms in the fluids and tissues of diseased persons is for the most part referable to the fact that certain changes have previously taken place (by deviations from healthy nutrition) in the constitution and vitality of such fluids and tissues, and that bacteria and allied organisms have appeared therein as pathological products—either by heterogenesis, or by what I have termed archebiosis, or birth direct from a fluid.

The evidence on which my belief is founded is of this nature.

1. Bacteria and their allies are found in greatest abundance during the life of the individual in connection with dying tissue-elements, and apparently are as plentiful within the dying epithelium of the cutaneous ducts, as in parts like the mouth, which are most liable to contamination with organisms from without. Again, they exist abundantly in and about the dying cells of bronchial mucus, although living bacteria appear to be almost completely absent from ordinary air.

2. The microscopical examination of such epithelial or mucous elements also favours the notion that the contained bacteria are products engendered within such cells, rather than mere results of an external contamination and imbibition. This opinion is based upon the following considerations. Bacteria only appear within the cell when it is obviously dying; and, in the case of epithelium, for instance, they manifest themselves at first as minute motionless particles scattered through the semisolid substance of the cell, where each particle grows into a distinct bacterium, which still remains motionless, and does not appear to divide for a long time. This is precisely similar to what I have observed over and over again, when *amebæ* in vegetable infusions get into an unhealthy condition and become resolved into nests of bacteria. They may exist for days in a state of activity with bacteria in the fluid around them, though none are to be seen in their interior. After a time, however, the chemical constitution of the fluid seems to become no longer suited to the *amebæ*, their activity ceases, they remain as almost motionless balls of jelly, and soon multitudes of the minutest particles appear throughout their substance, each of which straightway grows into a bacterium. The former *ameba* is converted into a mere bag of bacteria, which after a time ruptures, and thus liberates its swarming colony of newly engendered living units. Multitudes of mucus-corpuscles seem to undergo the same kind of change, so that bacterial degeneration takes place in the same manner, and is almost as typical amongst them, as is fatty degeneration amongst pus-corpuscles. The two kinds of degeneration, moreover, commonly occur side by side in epithelial *debris*. Bacterial degeneration takes place where the vitality of the unit is lowered, but where it is not sufficiently degraded to permit the still lower and more obviously destructive process of fatty degeneration; and if anyone wishes to see it in perfection, let him examine some central portion of the kidney, or other internal organ of a warm-blooded animal, five days or more after its death.

3. Bacteria are admitted by nearly all pathologists to be absent from the blood of healthy persons during life; and yet, in from eight hours to four or five days after death, according to the temperature of the air at the time, the previously germless blood of all individuals may be found to be swarming with these organisms in every stage of growth.

4. Whereas blister fluid or serum has been shown to be free from organisms in healthy persons, I have ascertained that, given a febrile patient with a temperature of 102 deg. Fahr., one can determine the presence of bacteria, at will, in any blister-bleb which remains intact for forty-eight hours or more, and this, too, where the patient does not suffer from any specific fever, but merely from pneumonic inflammation. I was led to ascertain this fact by finding, about eighteen months ago, myriads of bacteria in all the blebs of a patient suffering from acute pemphigus, with a temperature of 103 degs.

5. Lastly, as Dr. Sanderson has shown, a chemical irritant, such as liquor ammoniac, may be introduced beneath the skin of some of the lower animals in such a way as to "preclude the possibility of external contamination", and yet here, amidst tissues which he has shown to be germless, we may thus, within twenty-four hours, determine the presence of swarms of germs and organisms in the pathological fluids effused under the influence of the local chemical irritant.

This constitutes, as it appears to me, an exceedingly strong body of evidence tending to show that bacteria are pathological products capable of being engendered within the body after death, or in certain situations during life where tissue-elements are dying, or where the fluids of the body are notably altered by disease. It is true that the facts and considerations mentioned under 1 and 2 are capable of receiving another interpretation. It may be said, for instance, and it has actually been said by Dr. Beale, that the higher forms of life are, as it were, interpenetrated by the lower forms of life. Speaking of bacteria and their allies, Dr. Beale says:—"I have detected them in the interior of the cells of animals, and in the very centre of cells, with walls so thick and strong, that it seems almost impossible that such bodies could have made their way through the surrounding medium." (*Disease-Germs*, page 72, 1870.) And elsewhere the same observer says:—"Probably there is not a tissue in which these germs are not; nor is the blood of man free from them." Noting by the way that this latter statement does not accord with the experience of others, I may further mention that some distinguished pathologists, and notably

Dr. Burdon Sanderson, are also inclined to dwell strongly upon the fact of the wide distribution of bacteria throughout the body—not believing them to be innate or connate (in the mysterious manner imagined by Dr. Beale), but supposing that they have been introduced from without through certain definite channels.

Dr. Sanderson's views on this subject, and the means by which he supports them, are sufficiently remarkable to detain us a few moments. If what he says (BRITISH MEDICAL JOURNAL, February 13th, 1875) concerning the assumed easy absorption of bacteria from the intestine by lymphatics, and their subsequent passage into the blood, were in correspondence with actual facts, then, in face of the habitual prevalence of such organisms in the intestine, the blood of healthy individuals should scarcely ever be free from them. But this is surely proving too much, since Dr. Sanderson himself assures us that healthy blood is germless.

Again, the other main channel by which, as he says, bacteria may enter into the body abundantly from without, is through the bronchi and the lungs. Now, as a result of Dr. Sanderson's oft-quoted experiments in 1871, he claims to have proved "in the most striking manner . . . that air is entirely free from living microzymes". Speaking of a previously boiled Pasteur's solution, he says that "no amount of exposure" to air "has any effect in determining the presence of microzymes therein". And yet Dr. Sanderson now talks of the air which is "entirely free from living microzymes" being the channel through which these organisms are introduced into the lungs. It is true that, in his recently published lectures, this distinguished investigator makes a tacit retraction of his previous statement. He says, in fact, in his first lecture (BRITISH MEDICAL JOURNAL, January 16th, 1875):—"It must not be understood that bacteria do not exist in the atmosphere. But their existence there in an active form strictly depends on moisture. They attach themselves without doubt to those minute particles which, scarcely visible in ordinary light, appear as motes in the sunbeam or in the beam of an electric lamp. It is by the agency of these particles that they are conveyed from place to place." Elsewhere, in the same lecture (page 70), Dr. Sanderson repeats the statement, that "solid materials in suspension in the air" play a principal part in the conveyance of bacteria from place to place, and alleges that this was shown by the very experiments of 1871, which then entitled him to express the conclusion that "air is entirely free from living microzymes". All I can say is, that I have not been able to find in Dr. Sanderson's writings any explanation of this marked change of view, and that I certainly know of no experiments of his which at all establish the fact (extremely difficult as it would be to establish) that bacteria or their germs are conveyed from place to place on the surface of aerial particles, just as his assumed particles of contagium are supposed to be borne about by bacteria themselves. If the theory be true, the conditions for aerial locomotion of contagia are, at all events, becoming a little complicated. The contagious particles cannot move about alone; they must engage the services of bacteria to carry them, and these latter porters are unfortunately so delicately constituted, that they cannot exist alone in the atmosphere; they can only survive when borne on the backs of some moisture-containing fragments of atmospheric dust, which, though much heavier than the contagious particles themselves, are freely borne through the air in all directions.

Turning from these statements, therefore, as to the assumed modes by which bacteria habitually gain an entry into the healthy human body, I may say, that many of the methods by which Professor Kühne, Dr. Sanderson, and others (BRITISH MEDICAL JOURNAL, February 13th, p. 199), have attempted to ascertain whether the different tissues contain actual or potential germs, are pointless in the face of the statements of heterogenesis; since their methods cannot enable them to say, when positive results are obtained, that the potential germs from which, as they assume, the organisms have been developed are other than elementary particles of the previously healthy, though now altered, tissues, or that they have not been produced from the fluids which the tissues contain. These experimental observations are not only almost valueless on this account, but they are altogether needlessly complex. Why resort to heated knives, boiled thread, rapid movements, frequent immersions in paraffin at 260 deg. Fahr., paper boxes, warm chambers, etc., when precisely similar results might be obtained by simply leaving the dead animal alone for three or more days, and then subjecting the central tissues of either of the viscera to microscopical examination? So far as the principle of the method is concerned, or the kind of results which it may yield, it makes no difference whether we keep an extracted portion of tissue enveloped in paraffin in a warm chamber for hours or days, or resort to the much simpler method of leaving the animal unopened for several days before submitting its tissues to examination. In either case where organisms are found, this fact alone would give us no right to infer that they had developed from

pre-existing germs (in the natural history sense of that term); they may, on the contrary, have arisen either by heterogenesis or by archebiosis.

The weight of probability in favour of either of these two possibilities can only be judged of by resort to a different method of procedure; because, in view of the observed absence of bacteria from the tissues of such organs as kidney, liver, or brain, immediately after death, the subsequent multitudinous presence of organisms in these situations would, in the face of satisfactory independent evidence, be more easily accounted for by heterogenesis or archebiosis than by the hypothesis of pre-existing latent or potential germs. By an appeal to evidence of this kind, moreover, we are enabled to test the probability of the hypothesis previously referred to as being supported by Dr. Beale and others—viz., that which assumes the existence of invisible and mysteriously derived germs of bacteria and fungi throughout the elements of the tissues—an hypothesis somewhat wild in character, which has, I believe, no other foundation than the frequently observed prevalence of organisms in some of these situations.

With the view of settling these questions, therefore, we may carefully prepare an infusion from some animal tissue, be it muscle, kidney, or liver; we may place it in a flask whose neck is drawn out and narrowed in the blow-pipe flame; we may boil the fluid, seal the vessel during ebullition, and, keeping it in a warm place, may await the result, as I have often done. After a variable time, the previously heated fluid within the hermetically sealed flask swarms more or less plentifully with bacteria and allied organisms, even though the fluids have been much degraded in quality by exposure to this high temperature, and have thereby, in all probability, been rendered far less prone to engender independent living units than the unheated fluids in the tissues would be. We operate, however, under these disadvantageous conditions in order to make thoroughly sure that, by the preliminary heating, we have destroyed all pre-existing life within the flask; and, notwithstanding such adverse circumstances, we are able to obtain evidence of the occurrence of archebiosis. The researches of Kühne and others have fully shown that the protoplasm entering into the composition of the tissues of warm-blooded animals is coagulated and killed at a temperature of 111 deg. Fahr.; whilst my own investigations (*Evolution and the Origin of Life*, 1874, page 101) also show that bacteria and allied organisms are killed by exposure in the moist state to a temperature of 140 deg. Fahr.

Hence I contend that the wide distribution of bacteria throughout the human body in connection with dying tissue-elements in the most varied situations, and also in diseased fluids, is explicable most easily by assigning for many of them an origin by heterogenesis and by archebiosis (though when so produced they multiply rapidly in the ordinary fashion); and that my position—that bacteria are pathological products—is one which may claim to have been fairly established.

On this subject I would only add a word or two concerning the point of view and reasoning employed by those who seem willing to believe in almost any infringement of natural uniformity, rather than admit the occurrence of heterogenesis and archebiosis, or either of them alone. The most remarkable recent utterances on this subject are those of Dr. Sanderson, though it is only fair to say that they are somewhat typical of the line of argument adopted by many others.

Whilst admitting that bacteria in their "ordinary state" have been proved to be killed at a temperature of 140 deg. Fahr., and also by immersion in absolute alcohol, Dr. Sanderson assumes (BRITISH MEDICAL JOURNAL, February 13th, page 201) that other bacteria-germs may exist in an extraordinary state in which they have the power of resisting the influence of this temperature, the influence of absolute alcohol, and even the simultaneous action of both these destructive agents. But, if we ask on what amount of evidence this assumption is founded, many may be astonished to find that such an extraordinary belief has been adopted, simply because bacteria make their appearance in an organic infusion which has been prepared by macerating an organic extract previously submitted to the influences above mentioned, just as bacteria make their appearance within our closed flasks whose contents have been previously heated to the higher temperature of 212 deg. Fahr. Has it ever occurred to Dr. Sanderson that another interpretation might have saved him from the necessity of adopting this extraordinary belief?

Again, in his third lecture, the same investigator shows himself for the time similarly oblivious of the point of view of those who believe in archebiosis, whilst the argument made use of to support his own position is of a very surprising nature. After remarking (BRITISH MEDICAL JOURNAL, March 27th, p. 403) that "of all perishable things, protoplasm is amongst the most perishable", he goes on to state that bacteria possess "a wonderful property of passing into a state of persistent inactivity or latent vitality". This is nothing more than an explicit expression of the notion previously referred to, though I wish especially to call attention to the additional "evidence" upon

which the view is now based. Dust, containing organic *débris*, in which, as Dr. Sanderson confesses, he has no proof that anything living is contained, may be added to a fluid at the time barren, though freely capable of supporting life. One of the results of this addition is the appearance, after a short time, of bacteria. A physicist or chemist might conceive it possible that, as a consequence of such admixture, a compound not previously existing might have been more or less slowly formed—as this, at all events, is one of the modes by which new chemical compounds are engendered. But this point of view Dr. Sanderson will not seriously entertain—indeed, his remarks seem only explicable from the point of view of a foregone conclusion that archebiosis is an impossible process, and therefore on no account to be admitted as an interpretation of the facts. In reply to an imaginary objection, alleging that he had no proof that the dust contained anything living, he says with great naïveté:—"True; but I have proof that it contains that which produces life, and express this state of things, viz., the absence of manifestations of life on the one hand, and on the other the fact that the stuff in question possesses the power of impregnating something else which before was barren, by saying that the dust possesses latent vitality". The legitimacy of the inference does not seem very apparent to me, if it is to be taken in any other than a poetical sense; yet this is the only evidence adduced in favour of the assumed existence of an extraordinary state in which bacteria may exist—a state in which they are assumed to be capable of resisting influences which are admitted to be destructive to all actually known forms of life. Of course, on the same grounds, the physicist might argue that "friction possesses latent electricity", or the chemist that "oxygen possesses latent acidity", but it seems very questionable whether such statements would be regarded as serviceable additions to science. Neither can we consider that any further light is thrown upon this notion of "latent vitality" by Dr. Sanderson's concluding observations upon the subject, in which he says (BRITISH MEDICAL JOURNAL, April 3rd, p. 430):—"The vital activities of the organism are stored up for the future, the individual being for this very end endowed with the power of resisting external agencies, and thereby of enduring for an indefinite period". As to such teleological notions I have nothing to say; I prefer keeping to the region of fact and warranted inference. These, however, are the arguments by which a belief in the occurrence of archebiosis and heterogenesis is for the time averted.

Before drawing my remarks on this section of the subject to a close, I would point out that the views admitted by Dr. Beale and those who think with him, those admitted by Dr. Sanderson, Professor Kühne, and Dr. Tielgel, as well as those recognised by myself and others, all coincide with one another on a certain common ground. We are agreed as to the fact that bacteria are abundantly present within the body, or that they may appear therein under certain conditions independent of any immediate external contamination—however much we may differ amongst ourselves as to the interpretation of their presence, actual or possible. Yet this common ground contains an admission which is decidedly inimical to Mr. Lister's theories. Following M. Pasteur, this distinguished surgeon would have us believe, that whilst bacteria are disease germs, they do not naturally exist within the body. He has based his antiseptic system of treatment on the assumption that air, or surfaces which have been exposed to it, coming into contact with wounded portions of the body, are the means by which his assumed animated poisons are introduced into the system. But it is, I think, now well known that the whole pyæmic process may be met with occasionally, even where there is no abrasion of the surface of the body. And, moreover, as regards the cause of the disease in persons with open wounds, I may say that Pasteur never seriously attempted to discriminate between the respective effects of the living and the dead elements entering into the composition of atmospheric dust. Effects which were often due to the action of mere organic *débris* he attributed to the influence of living germs (*Evolution and the Origin of Life*, pages 103-114); and in this respect M. Pasteur has been followed by Professor Lister.

But, as I take it, the essential practical fact which Professor Lister wishes to enforce is, that the putrefactive processes apt to take place in wounds ought to be reduced to a minimum, because it seems certain that, during such processes, poisons are liable to be engendered whose absorption or local influence upon the system may be attended by the most fatal results. Such a notion, which is assuredly thoroughly well founded, may, however, be acted upon by the adoption of the antiseptic system of treatment (or by free exposure of wounds and frequent removal of secretion), quite independently of the question whether mere organic *débris* may act as ferments, and also quite independently of the further question whether the poisons engendered in wounds are living entities or complex chemical compounds not endowed with the attributes of living matter.

Applicability of the Germ-Theory to Artificial Tuberculosis, Syphilis, Typhoid, Typhus, Relapsing Fever, Cholera, Measles, Scarlet Fever, Small-pox, and other Contagious Fevers.—I now pass to a consideration of the germ-theory in its relation to another class of diseases, although I do not wish to convey the idea that there exists in nature a distinct boundary line, such as my division of the subject might indicate. It must be clearly understood, that the local morbid processes or inflammations of a virulent type—which may or may not gradually entail a more general morbid condition—pass insensibly, by means of such affections as artificial tuberculosis and syphilis, into that class of diseases under which are included such affections as typhus, typhoid, relapsing fever, cholera, measles, scarlet fever, small-pox, and other contagious fevers. Affections like artificial tuberculosis and syphilis might, therefore, have been placed with equal appropriateness in either of the divisions I have adopted.

The treatment of the present part of my subject may be disposed of in a more summary manner than the last, principally because many of the facts and considerations which were advanced in reference to virulent inflammations and their sequelæ, and the presence of independent organisms in the altered fluids and tissues of the body, are also applicable to the question of the relation of such organisms to the more specific contagious fevers.

The case to be made out in favour of the germ-theory, as applied to these latter fevers, is also, in my opinion, much weaker than it is in respect to the virulent inflammations and their sequelæ; since, although such contagious fevers have always been regarded as general and essentially "blood-diseases", in only one of those occurring at all commonly in the human subject does it appear that anything like an independent living organism is to be met with in the blood. There is, therefore, here a *prima facie* inherent weakness in the whole theory, which I think a thorough examination of the question will strongly tend to confirm, rather than dissipate.

The reasons relied upon in favour of the germ-theory, as applied to these diseases, are of a purely *a priori* or theoretical nature, and such as I have already referred to. They are, in fact, based upon the assumed nature of contagium, and upon its assumed mode of increase within the body. How little conclusive such *a priori* reasons are, and how the facts may be otherwise explained I have already endeavoured to show, and as the theory in its applicability to these diseases rests upon absolutely no positive evidence that I am aware of, I am compelled to leave a gap here, and pass on to a brief enumeration of the facts and considerations which seem to tell strongly against the existence of any causal relationship between organic germs and these specific contagious fevers.

1. With two exceptions, no definite germs or organisms are to be met with in the blood of patients suffering from these diseases during any stage of their progress.
2. The virus or contagium of some of these diseases, whatever it may be, does not exhibit the properties of living matter.
3. On the other hand, the virus or contagium of most of these contagious diseases with which definite experiment has been made, is most potent in the fresh state, whilst its power very distinctly diminishes in intensity as organisms reveal their presence more abundantly therein—facts which would seem to point to the conclusion, or at least are quite consistent with the notion, that the contagious poison may be a chemical compound which gradually becomes destroyed or modified by the successive changes taking place in association with processes of putrefaction.
4. There is the extreme improbability of the supposition that this whole class of diseases should be caused by organisms known only by their effects.
5. The facts of the sudden cessation, periodical visitation, and many of the other phenomena of epidemics, however difficult they may be to explain upon any hypothesis, seem to oppose almost insuperable obstacles to the belief that living organisms are the causes of such epidemics of specific contagious diseases.

It would seem little better than an ill-timed attempt at jesting to postulate the existence of distinct germs for these several specific fevers, and at the same time to endow such imaginary entities with properties different from those of all known germs. To remain always in the germ stage in media favourable for their multiplication would, even if the imaginary germs were visible, be contradictory to all previous experience; but to suppose, in addition, that such hypothetical invisible entities are capable of resisting the influence of agencies which have been proved to be destructive of all known living matter, would seem to be going altogether beyond the bounds of probability. And, if we look at the question from this point of view, we may regard it as a definitely established fact that the virus of cholera, for instance, is not composed

of living germs or particles. Messrs. Lewis and Cunningham have shown (*Report, etc., into the Nature of the Agent or Agents producing Cholera*, pp. 46 and 57, 1874) that the virus is not appreciably impaired in activity when the fluids containing it have been raised for a few minutes to a temperature of 212 deg. Fahr.; and, in reference to this subject, they say: "We have seen no living object preserve its vitality after exposure in a fluid to a temperature approaching to 212 deg. Fahr., nor have we been able to satisfy ourselves that anyone else has done so."

In only one of the specific fevers commonly met with in the human subject have organisms been found in the blood: this exception is relapsing fever. There is, however, an affection occasionally communicated from cattle (*sang de rate*, or splenic fever) in which organisms are occasionally met with in the same situation. But the fact of the existence of actual visible organisms in these cases seem altogether robbed of its significance, after the occurrence of archæobiosis and heterogenesis in diseased fluid and tissues has been demonstrated. The view, indeed, that the organisms found in these affections owe their origin to certain changes prone at times to occur in the fluids of the body, is directly supported by some of the most interesting results of Dr. Sanderson's experiments concerning pyæmia. He tells us that in some of the lower animals artificial tuberculosis and pyæmia are often only different effects of the same cause. That is, that some of the same inoculating material may be introduced beneath the skin of two rabbits, and in the one a slow and more chronic set of morbid changes is induced (tuberculosis), whilst in the other more acute and rapidly fatal processes are established (pyæmia). In the former animal no organisms are to be found in the blood, whilst the blood of the latter, according to Dr. Sanderson, is swarming with them. Changes in the character of the morbid process, therefore, may occasionally favour the presence of organisms. Nay, further, we see the same kind of difference in another way. Pyæmia and septicæmia, as they occur in some of the lower animals, differ in one very notable respect from the same diseases as they occur in man. Whilst in the lower animals bacteria are to be found in the blood of the living animal, in man they are always absent during life. With such facts as these before us, and others previously referred to concerning the absence and presence of organisms in blister-fluid from different individuals, it need not excite much surprise if we find that organisms are to be found in the blood of persons suffering from one or more of these specific contagious fevers.

There are, however, three other diseases of this class in which organisms, though absent from the blood, are to be met with in those parts of the body which are severally the special seat of morbid change. The three diseases are—vaccinia, ovine small-pox (which seems to be altogether similar to the disease occurring in man), and typhoid fever.

That the organisms of the vaccine vesicle have any significance other than from being possible instances of heterogenesis or archæobiosis, I find it difficult to believe. Even if the contagious property of the fluid be resident in some of its particles, as the observations of M. Chauveau and Dr. Sanderson seem to prove, still such particles may exist and yet not be the independent organisms existing in the same fluid. The fact that as the organisms increase in the fluid with age the virus loses its intensity, and the fact that it may remain potent even after prolonged periods of desiccation, are both of them strikingly opposed to the notion that the living organisms of the fluid are its active elements in a specific sense. On the other hand, it does appear, from the experiments of the late Dr. Henry, of Manchester, that vaccine virus loses its intensity when subjected to a temperature of 140 deg. F.

In ovine small-pox we have, as Dr. Klein's very interesting researches have shown (*Proceedings of the Royal Society*, No. 153, p. 1874), a local appearance and active growth of organisms taking place in the skin in connection with its characteristic pustules; whilst in typhoid fever we have also an active growth of rather different organisms in the substance of the ileum, and more especially in the tissues constituting Peyer's patches—that is, in connection with the anatomical marks of this disease. (BRITISH MEDICAL JOURNAL, December 5, 1874.) But just as a mere chemical irritant (ammonia) injected beneath the skin of a rabbit produces, as Dr. Sanderson tells us, a local inflammation in which the fluids effused swarm with bacteria, why may not the morbid processes taking place within the skin in small-pox engender irritants which may lead to the appearance of somewhat similar products? Hence, in face of the evidence already detailed concerning the occurrence of heterogenesis, the presence of organisms in connection with small-pox lesions may be readily accounted for, without the necessity of attaching any very important rôle to them. And as regards the presence of organisms in Peyer's patches and adjacent parts, in cases of typhoid fever, no greater importance could be accorded to this association by any but enthusiastic germ-theorists. For, even if the reasons above alluded to

were not very influential with them, there is another mode of looking at the matter, from quite an orthodox point of view, which would equally assign to the local development of organisms a very subordinate rôle. Morbid tissues are generally admitted to form a favourable nidus for fungoid growths, and the intestine is known to contain the germs or spores of such bodies. The flourishing growth of leptothrix and fungi in the diseased mucous membrane may therefore be only another example of an already well-known class of effects: so that, looking at the question from all sides, it seems to me, in the present state of our knowledge, to be extremely improbable that these newly discovered organisms have any causal relationship to typhoid fever.

It only remains for me now to make a few very brief concluding observations—(1) concerning Pasteur's recent important modifications of his germ theory of fermentation; (2) upon the degree of relationship existing between fermentation and zymosis; and (3) as to the probable mode of action of ferments and contagia.

1. Pasteur has, within the last two years, made a most important modification in his theory of fermentation (*Compt. Rend.* 1873-4). Whilst he formerly held that fermentation and putrefaction are chemical processes initiated by independent organisms (bacteria and their allies), and taking place in correlation with their growth and multiplication, he has of late shown that similar phenomena may be initiated by the chemical processes taking place in the tissue-elements of certain fruits and vegetable tissues, when these are placed under certain abnormal conditions. Grapes, for instance, suspended in an atmosphere of carbonic acid, will undergo fermentation, so as to generate alcohol and other products, even without the presence of torule or allied organisms. Other fruits and vegetables treated in the same way behave more or less similarly. Organic multiplication of independent organisms has therefore now been shown, by Pasteur himself and his followers, not to be an essential factor in the process of fermentation. With this admission, I believe it will be found impossible hereafter consistently to entertain an exclusively "vital" theory of fermentation, and equally impossible to resist accepting the broader physico-chemical theory, and with it the almost inseparable correlative doctrines of archæobiosis and heterogenesis.

M. Pasteur, in fact, now proves that fermentation takes place under the influence of altered chemical (nutritive) processes taking place in unhealthy vegetal tissue, just as we know that similar processes may be initiated under the influence of a physico-chemical process brought about by finely divided platinum. As Döbereiner pointed out, this material "has the power—and many organic substances have a similar power—of absorbing oxygen from the air, and bringing it into a condition in which it can unite with other substances with which it would not otherwise enter into combination at low temperatures" (*Beginnings of Life*, vol. i., p. 409).

And MM. Lechartien and Bellamy, following up the recent experiments of Pasteur, have found (*Compt. Rend.*, November 2, 1874) that in these modified processes of fermentation, taking place in vegetal tissues, independent organisms, though they are usually absent at first, not unfrequently make their appearance after a time. In the process as it occurs in beetroot and in the potato, on the other hand, bacteria habitually spring into existence or reveal themselves in great abundance soon after the commencement of a well-marked process of fermentation. M. Pasteur will, I suspect, find it difficult consistently to account for these facts, without admitting his long-postponed acceptance of doctrines of "spontaneous generation."

2. Respecting the degree of relationship existing between fermentations and zymotic processes, something more definite may now be said. Between the ordinary, previously known forms of fermentation, and zymosis, a most fundamental difference exists, which has hitherto been far too much lost sight of. It is this. Whereas in an ordinary fermenting fluid the changes initiated by a ferment take place in a mere isolated mixture of organic substances, in zymotic processes the changes initiated by contagium occur in the fluids and tissues of a complex living body. That this latter fact does exercise a very important influence, and that the two processes are not so similar as they have been supposed, we may now more readily recognise, since the processes of fermentation occurring in vegetal tissues have been investigated. The relationship existing between zymosis and these modified processes of fermentation taking place in fruits and tubers seems, indeed, far more close than that between the zymotic processes in animals and ordinary kinds of fermentation.

In the process occurring in vegetal tissues, as well as in those morbid processes which take place in the animal organism, the presence of rapidly multiplying independent organisms is an occasional rather than a necessary feature. Though usually absent in other allied processes, yet do we find organisms invariably manifest themselves throughout

the tissues of beetroot and of the potato, when these are placed under certain abnormal ("unhygienic") conditions. And, though usually absent from the blood of persons suffering from specific contagious fevers, yet do we also find organisms invariably showing themselves in the blood of persons suffering from some of them—such as relapsing fever and splenic fever. Nay, further, under the influence of a "change of conditions" alone, we may initiate these modified fermentative processes in vegetables—that is to say, in ordinary parlance, the processes may originate "spontaneously" or *de novo*. But if the modified activity of tissue-elements suffices to initiate such morbid processes in the vegetal organism, why may it not occasionally do the same in the animal organism? This is a point of view which seems too valuable to be lost sight of, more especially in the face of the results yielded by our flask experiments.

3. In conclusion, I would maintain that the facts already known abundantly suffice to displace the narrow and exclusive vital theory, and to re-establish a broader physico-chemical theory of fermentation.

Whether the "ferment" in any given case be an independent living organism, a tissue-element, a fragment of not-living organic matter, or some mere physico-chemical influence (as in the case of the action of finely divided platinum), the initiative fermentative change is in each case a result of chemical action. And similarly, with regard to "contagium", whether it be an altered though living tissue-element, a fragment of dead organic matter, a chemical compound (or even the more vague influence of a "set of conditions", which may suffice to generate *contagium de novo*), we have in each case to do with gradually initiated chemical changes, distinctive in kind, and gradually terminating in one or other of the recognised varieties of zymotic affections. The changes in each case where we happen to have to do with living ferments or living contagia would be due only to an infinitesimal extent to the organic multiplication of such living unit, though the decompositions set up by them in their respective fluids may be such as to lead to the formation of a continuous new birth of independent organisms, all of which exhibit most active powers of multiplication. The organisms produced in such cases are, therefore, only to an infinitesimal extent lineal descendants of the original living ferments or contagia, under whose influence such fermentative or zymotic processes were originally established. (*Beginnings of Life*, vol. ii., p. 361.)

Thus it would appear that the original notion borrowed from the vital theory of fermentation, that all the organisms met with in a fermenting mixture are in the strict sense of the term lineal descendants of those originally introduced as ferments, would disappear with the vital theory itself. Yet this has been the notion upon which upholders of the germ-theory of disease have always relied confidently, in explanation of the mode of increase of contagium within the body.

Looking, however, at this question from our new point of view, may we not say that chemical changes established in some one tissue, or in many, may, by dint of altered blood and other secondary processes, spread so as to be initiated also in previously sound parts; and that thus throughout the body, or in some special regions of it, living tissue, endowed with peculiar poisonous properties, or complex alkaloidal compounds, may be engendered in enormous quantities, some of which may be thrown off from this or that surface, and act after the fashion of "contagia" generally.

THE TEMPERATURE IN PHTHISIS.

SHORTLY after the publication of Dr. Sidney Kinger's work on the *Use of the Thermometer in Phtisis*, I made a number of thermal observations on phthisical patients, and came to the conclusion that valuable as the thermometer is in the diagnosis of a variety of diseases, yet, as a test of the deposition of tubercle, it is unreliable. In cases of incipient phthisis, with obscure physical signs, it did not aid the diagnosis; it was unsafe to say that there was no disease because the temperature was normal. In many cases, there was no rise, yet signs of tubercular deposit gradually unfolded themselves. In others, a rise of two or three degrees occurred, but often there was slight bronchial inflammation which might account for it. In more advanced cases, there was of course softening, and often subacute pneumonia, bronchitis, etc. I believe that the thermometer indicated only the pyrexia produced by these complications. Subnormal temperature was occasionally observed when the vital powers were low. I several times intended to record these observations, but feared they were not sufficiently elaborate to satisfy the profession, although they convinced me. Dr. Theodore Williams has now more efficiently done so; and it is satisfactory to find his conclusions tally with mine.

H. STRANGWAYS HOUNSELL, M.D., M.R.C.P. Lond., Physician to the Western Hospital for Consumption, Erith House Institution, etc., Torquay.

ON THE ACTIONS OF PICROTOXINE, AND THE ANTAGONISM BETWEEN PICROTOXINE AND CHLORAL HYDRATE.

By J. CRICHTON BROWNE, M.D., F.R.S.E.,
Medical Director of the West Riding Asylum.

(Continued from page 444.)

CERTAIN conclusions having thus been arrived at as to the actions of picROTOXINE and as to the toxic symptoms produced by it when uninterfered with by treatment, it became necessary in the next place to ascertain accurately the minimum fatal dose of it, in those animals which it was proposed to make use of, in testing the supposed antagonism between it and chloral hydrate. The results of the experiments which were performed with this view are shown in the two following tables.

TABLE II.—Showing the Minimum Fatal Dose of PicROTOXINE in Rabbits.

No.	Weight of Rabbits.	Dose of PicROTOXINE in parts of a grain.	Effects.	Result.
9	2 lbs. 6 oz.	1-60th	Dulness, hurried breathing, and prostration	Recovery
10	3 lbs. 2 oz.	1-40th	Lethargy and unsteadiness in movements	"
11	3 lbs. 2 oz.	1-30th	Dulness, quickened respiration, restlessness, twitching of ears	"
12	3 lbs. 7 oz.	1-25th	Lethargy, hurried respiration, twitchings	"
13	3 lbs. 9 oz.	1-25th	Prostration, hurried respiration, severe twitchings	"
14	3 lbs. 3 oz.	1-20th	Lethargy, restlessness, violent convulsions	Death in 81 min.
15	2 lbs. 12 oz.	1-20th	Dulness, twitchings, violent convulsions	Death in 75 min.
16	3 lbs. 3 oz.	1-8th	Lethargy, hurried breathing, trembling, violent convulsions	Death in 32 min.
17	2 lbs. 2 oz.	1-3rd	Drowsiness, twitchings, violent convulsions	Death in 30 min.
18	2 lbs. 15 oz.	2-3rds	Staggering, loss of power in legs, violent convulsions	Death in 19 min.

TABLE III.—Showing the Minimum Fatal Dose of PicROTOXINE in Guinea-Pigs.

No.	Weight of Guinea-Pig.	Dose of PicROTOXINE in parts of a grain.	Effects.	Result.
19	1 lb. 2 oz.	1-55th	Lethargy, followed by restlessness, with twitchings of ears	Recovery
20	1 lb. 6 oz.	1-50th	Dulness, quickened respiration, twitchings of ears and mouth	"
21	1 lb. 4 oz.	1-40th	Dulness, hurried respiration, twitchings, three severe fits, with tonic and clonic spasms	"
22	1 lb. 5 oz.	1-35th	Lethargy, restlessness, twitchings of ears and mouth, loss of power in hind legs	"
23	1 lb. 5 oz.	1-30th	Drowsiness, hurried breathing, restlessness, three fits, then constant convulsions	Death in 123 m.
24	1 lb. 2 oz.	1-30th	Lethargy, twitchings, violent convulsions	Death in 62 min.
25	1 lb.	1-30th	Liveliness, startings, violent convulsions	Death in 40 min.
26	1 lb. 2 oz.	1-20th	Lethargy, twitchings, violent convulsions	Death in 75 min.
27	1 lb. 6 oz.	1-4th	Lethargy, hurried breathing, startings, violent convulsions	Death in 25 min.

These tables demonstrate that one-twentieth of a grain of picROTOXINE may be regarded as the minimum fatal dose in a rabbit weighing about three pounds, and that one-thirtieth of a grain may be regarded as the minimum fatal dose for a guinea-pig weighing about a pound and a quarter. This point having been satisfactorily settled, the next experiment was directed to ascertain whether, as had been supposed, the action of the picROTOXINE could be modified or controlled by chloral hydrate.

Experiment XXVIII.—A vigorous rabbit, weighing exactly three pounds, was procured, and to it one-twentieth of a grain of picROTOXINE was administered by hypodermic injection, ten grains of chloral hydrate being simultaneously administered in the same way. Ten minutes after the injection, the rabbit was heavy and dull; and, five minutes later, its bowels having in the meantime acted very freely, there was superadded to the dulness some drowsiness. It still rested upon its feet, but its head drooped to one side. The breathing was exceedingly rapid. Twenty minutes after the injection, it was drowsy, but still sitting up, and able to move away at once when pinched or disturbed. The

respirations were at the rate of 140 per minute, and somewhat irregular. Forty minutes after the injection, it remained in nearly the same condition, except that it was stretched out upon the floor, and looked more prostrated. It did not scream when its tail was pinched, but simply moved away from the annoyance. Fifty minutes after the injection, it was uneasy, and frequently changed its position. It was still sitting up, and able to move about, though with some unsteadiness. Seventy minutes after the injection, it lay upon its belly, with its limbs stretched out, but could still spring on to its feet when disturbed. Ninety minutes after the injection, it got up voluntarily, and sought out a dark corner, in which it ensconced itself. One hundred and twenty minutes after the injection, it was quite well, and eating freely. From first to last, there were no tremblings, no spasms of any kind, and no deep sleep nor coma.

Experiment XXIX.—A guinea-pig, weighing 1 lb. 4 oz., had one-thirtieth of a grain of picrotoxine injected at the same time with five grains of chloral-hydrate. In seven minutes, it was very drowsy, and in eleven minutes it was sleeping quietly. In twenty-six minutes, its sleep was unquiet, and it often awoke, got up, changed its position, and then dropped off to sleep again, its breathing all the time being very rapid. In forty minutes, it was awake, looking about it, and moving a good deal. In fifty minutes, it had again fallen into a sleep; from which, however, it could be readily roused. In seventy minutes, it was still asleep, but restless, and tossing about from time to time. In ninety minutes, it was sleeping quietly; and in this state it remained until three hours after the injection, when it awoke up quite recovered. From first to last, there were no spasms, and no profound comatose sleep.

These two experiments were regarded as very remarkable, and as clearly indicating the existence of the antagonism which had been suspected. It was felt, however, that a much larger body of proof was requisite for its full demonstration; and accordingly the series of experiments summarised in the following tables was next undertaken.

TABLE IV.—Showing the Effects of the Hydrate of Chloral Injected with Fatal Doses of Picrotoxine in Rabbits.

No.	Weight of Rabbit.	Dose of Picrotoxine in parts of a grain.	Dose of Chloral Hydrate in grains.	Effects.	Result.
30	2 lbs. 14 oz.	1-20th	10	Drowsiness, disturbed sleep for two hours	Recovery
31	3 lbs. 1 oz.	1-20th	12	Drowsiness, hurried breathing, deep sleep for 2 hours	"
32	2 lbs. 8 oz.	1-16th	15	Drowsiness, sleep easily disturbed	"
33	3 lbs.	1-15th	12	Prostration, hurried breathing, twitchings of head and ears	"
34	3 lbs. 4 oz.	1-8th	15	Dulness, hurried breathing, twitchings, five severe fits	"
35	3 lbs. 6 oz.	1-4th	21	Twitchings, convulsions, drowsiness, deep sleep	"
36	2 lbs. 13 oz.	1-3rd	20	Drowsiness, lethargy, twitching, violent convulsions	Death in 21 hrs.
37	2 lbs. 11 oz.	one-half	20	Drowsiness, hurried breathing, twitchings, violent convulsions	Death in 6 hrs.
38	2 lbs. 14 oz.	2-3rds	24	Restlessness, hurried breathing, drowsiness, sleep, twitchings, violent convulsions	Death in 59 m.

TABLE V.—Showing the Effects of the Hydrate of Chloral when Injected with Fatal Doses of Picrotoxine in Guinea-Pigs.

No.	Weight of Guinea-Pig.	Dose of Picrotoxine in parts of a grain.	Dose of Chloral Hydrate in grains.	Effects.	Result.
39	1 lb. 12 oz.	1-30th	5	Drowsiness, sleep, but not so profound as chloral sleep usually is	Recovery
40	1 lb. 4 oz.	1-30th	5	Drowsiness and disturbed sleep	"
41	1 lb. 6 oz.	1-20th	6	Drowsiness, restless, disturbed sleep	"
42	1 lb. 2 oz.	1-16th	7	Drowsiness, restlessness, twitchings, broken sleep	"
43	1 lb. 4 oz.	1-8th	16	Drowsiness, twitchings, violent convulsions	Death in 4 hrs.
44	1 lb. 7 oz.	1-8th	8	Lethargy, restlessness, twitchings, hurried breathing, coma	Death in 10 hrs. and 40 min.
45	1 lb. 3 oz.	1-4th	10	Drowsiness, deep sleep, coma	Death in 7 hrs.
46	1 lb. 7 oz.	1-4th	6	Restlessness, startings, convulsions	Death in 90 m.

As these experiments progressed, it became abundantly evident that chloral-hydrate counteracts the effects of poisonous doses of picrotoxine in the most decisive manner, and that the antagonism which exists between them is one of the most striking instances of antagonism that has yet been discovered. For, whereas the largest dose of strychnia which has yet been antagonised by chloral-hydrate in a rabbit—one-fortieth of a grain—is just about equal to two minimum fatal doses, the largest dose of picrotoxine that has been so antagonised—one-fourth of a grain—is equal to five minimum fatal doses; and, whereas the prolongation of life in the rabbit by chloral-hydrate after doses of strychnia, which it was powerless altogether to antagonise, has never exceeded eight times the period in which life is destroyed by the same dose of strychnia unmodified by treatment, the prolongation of life in the rabbit by the same agent, after doses of picrotoxine under similar circumstances, has amounted to as much as forty-eight times the period in which death would have ensued, had the picrotoxine been uninterfered with in its action.

When the minimum fatal dose of picrotoxine—one-twentieth of a grain—was administered, and with it ten or twelve grains of hydrate of chloral, the rabbit, instead of dying in about an hour and a half after violent convulsions, perfectly recovered after a more or less disturbed sleep of two or three hours' duration; and the same rabbit that thus recovered was killed about a week later by the repetition of the same dose of picrotoxine—one-twentieth of a grain given alone—within one hour and a half of its administration. When one-fifteenth or sixteenth of a grain of picrotoxine was given with twelve or fifteen grains of chloral, perfect recovery took place after a prolonged sleep, broken in upon by restlessness and trifling twitchings. At and beyond this point, no crucial experiment, consisting in the repetition of the same dose of the poison, after a suitable interval, without the antidote, was deemed necessary. Such an experiment, indeed, would have been but an useless waste of life, as I have never seen a rabbit recover after a sixteenth of a grain of picrotoxine. Having received such a dose, rabbits invariably die within an hour, after severe convulsions. When one-eighth of a grain of picrotoxine was administered with twelve grains of hydrate of chloral, satisfactory recovery took place, but after a succession of symptoms which revealed outwardly in a singular manner the struggle for the possession of the nervous system which was going on within by the two opposing agents. So nearly were their forces matched in this instance, that the conflict was severe and long maintained, and the ascendancy was gained by each in turn; the victory, however, finally falling, not to the bane, but to the antidote. The drugs were administered at 3.30 P.M., and ten minutes thereafter the rabbit was drowsy, its head nodding, and its breathing being exceedingly rapid. In eighteen minutes, it was lively, and able to move about; but in twenty-four minutes it was very feeble, and swayed visibly when it attempted to walk. In twenty-five minutes, there were shakings of the head from side to side, and twitchings of the ears, lasting just six seconds. The instant these movements terminated, the animal manifested great drowsiness, nodded repeatedly, and then let its head fall flaccid on one side. In twenty-eight minutes, sleep having lasted for three minutes, there were a start and sudden awakening, and then drawing back of the head and rapid twitchings of the ears and mouth, continuing eight seconds, and again merging into sleep. In thirty-three minutes, there occurred another seizure. This time the head was drawn back, the fore-paws were spread out, and the body then reared aloft on them; while the lips and ears were sharply agitated. During the fit, pinching the tail secured no response; but whenever the fit was over, and the animal had fallen asleep, the same irritation caused waking and movement, but no cries. The breathing immediately before and after the fit was so rapid as to be uncountable; but during the interparoxysmal sleep it became gradually slower. In thirty-six minutes, there was another fit like the preceding, except that the head was drawn to the right side. At the close of this fit, and before the supervention of sleep, there was a sharp attack of sneezing. In forty minutes, there was another fit, in which the head was violently shaken, and in which the munching movements were very vigorous. In the sleep of four minutes' duration which followed upon this fit, there was occasional slight shaking of the head (the rabbit was still in a sitting attitude), which did not, however, interrupt sleep. In forty-four minutes, there was another slight attack of clonic spasms, limited to the head, and accompanied by a free flow of saliva from the mouth. Subsequently to this, no twitchings occurred; the rabbit fell into a deep sleep, which lasted for an hour and a half; and then it awoke and began to scramble about. It remained in a feeble and stupid state for three hours more, and was not altogether well until next morning.

In this case, the dose of chloral-hydrate given was rather too small, absolutely, and from the first, to counterbalance the effects of the

microtoxine, so that the contest between them became visible. Had twenty instead of fifteen grains of chloral-hydrate been administered, it is probable that no fits would have occurred.

When one-fourth of a grain of microtoxine and twenty-one grains of chloral-hydrate were injected simultaneously, the phenomena observed were very like those described above, except that, after about a dozen separate fits and intermediate sleep harassed by frequent twitchings, there was a short period of continuous clonic spasms, in which, for about three minutes, the head was drawn back, and the fore-paws went through active running movements, which were arrested by deep and protracted sleep. When still larger doses of microtoxine were administered to rabbits, as one-third, one-half, and two-thirds of a grain, with from twenty to twenty-four grains of chloral, evidences were not wanting of the extraordinary power of the latter drug to modify, arrest, and mitigate the effects of the former. Although, in these cases, the chloral-hydrate failed to ward off death, it marvellously extended life, and reduced the severity of the most distressing symptoms. With such enormous doses of microtoxine, much larger doses of chloral-hydrate than were resorted to would be called for, in order to render it efficacious as an antidote—doses so large, indeed, as to be in themselves poisonous to a degree not to be counterbalanced by microtoxine. The rabbits that received these enormous doses perished from the microtoxine and an insufficiency of chloral. In one, life was drawn out and slight twitchings persisted for twenty-four hours, death then being due to exhaustion; and, in the other, death was due to the terrible convulsions and their immediate consequences.

[To be continued.]

THERAPEUTIC MEMORANDA.

INTERNAL ADMINISTRATION OF TAR IN PSORIASIS.

IT may not be out of place if I avail myself of the opportunity afforded by the publication in the JOURNAL of March 20th, of the researches of Dr. Ringer and Mr. Murrill into the value of the ingestion of tar in winter-cough, to state the results of an investigation as to the value of the ingestion of tar in psoriasis. A distinguished teacher, under whom both Dr. Ringer and I studied, was in the habit of treating his cases of psoriasis with tar administered simultaneously internally and externally, and used to impress the memory of the fact on the minds of his class by telling them that such patients should be done to as Noah did to his ark; that is to say, they should be pitched within and without; and his patients certainly did well under the treatment. This led me to feel curious to know which of the two was the more important—pitching within or pitching without. I accordingly, as soon as I had hospital patients of my own, dealt with all my cases of psoriasis for some time as follows. The first had tar-ointment and camphor mixture; the second had tar internally in the shape of tar-capsules, without other treatment of any kind; the third was treated like the first; and so on with about thirty cases in all—the odds being simply pitched without, the evens being impartially pitched within. At the end of a couple of months, a very decided result was obtained. Those pitched without had all very considerably improved, and some were perfectly well. Those pitched within remained very much as before, some of them being even worse than at first. To obviate the possible contingency of those pitched within being obstinate cases, they were next pitched without, and they all of them thereupon began speedily to undergo improvement. In administering tar internally in this experiment, I pushed it in every case *ad nauseam*. I began with a stronger dose than an ordinary tar-pill, namely, a tar-capsule three times a day. I increased this dose by doubling it, and then by trebling it in cases where it could be borne without excessive nausea; but in no case did it seem to do the least perceptible good. The experiments of so pre-eminently able an observer of the action of drugs as Dr. Ringer prove without question that tar is capable of producing an effect on organs remote from those to which it is applied. I am unable, therefore, to offer any explanation of the results I arrived at. I can only offer my experiment to him, in the hope that he may think it worth while to repeat it and report whether or not I am correct in my conclusion, that tar taken internally has no effect in curing psoriasis, although its local application to the disease has in all cases a decidedly beneficial effect, and in many is of itself sufficient to cause the complete disappearance of the eruption.

BAIMANSO SQUIRE, M.B.

ON THE USE OF DIGITALIS IN THE TREATMENT OF SOME CASES OF BRONCHITIS.

GIVEN a patient past the meridian of life, either very stout, or emaciated from previous bad health, and let him, or more commonly her,

have a neglected bronchitis, and we have the following class of symptoms produced: A perspiring skin, a poor and quick pulse, urgent dyspnoea, bluish tinge of lips and skin, and respiration accompanied by loud wheezing sounds. The most successful plan of treating these cases, so common during the present severe winter, is the free administration of digitalis, which may be advantageously combined with the compound spirit of ammonia. The digitalis may be given in doses of ten minims of the tincture every two hours. In less urgent cases, the pills recommended by Dr. Fothergill, in his Hastings prize essay published in this JOURNAL, are very useful, and have the advantage of less easily inducing sickness than the tincture. In these cases, it is the heart which is at fault, the right ventricle being gorged with blood, which it is unable to propel through the lungs. The best test of the truth of this theory is its success, for the pulse will be found to become full and slow, and the breathing relieved, directly the digitalis has had time to act on the heart. Its action is sometimes assisted by the judicious administration of a little alcohol. I prefer common gin. If, however, it be found that these cases of commonly called bronchitis are really dependent, for their non-recovery at least, upon weak hearts, care must be taken as to the administration of stimulants, for they accelerate the action of the heart, and in the end weaken it. In fact, digitalis slackens the speed, and stimulants increase it, so they to some extent contradict each other. I have had some cases lately in which twenty minims of tincture of digitalis were given every two hours for a whole day, and then decreased to ten minims every four or six hours. This medicine will be found to be chiefly valuable when the pulse is weak and rapid. In one old lady about 80 years of age, the effect was remarkable, and in another, seen to-day, the pulse has fallen to 76, with corresponding relief to the other symptoms. In another case, in which the pulse was 130 and very weak, it acted magically, but I am sorry I made no note of the exact rate to which the pulse fell. Good support of all kinds may at the same time be given. I like stimulants less and less in this form of disease; if you want a horse to go one mile rapidly and well, the spurs may be used, but for a long journey a steady pace is better. Some patients are more susceptible of digitalis than others, therefore the effects must be watched, and the dose increased or diminished, as necessary.

JAMES BRAITHWAITE, M.D., Lond., M.R.C.S.,
Assistant-Surgeon to the Hospital for Women and Children, Leeds.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

ALL SAINTS INSTITUTION, GOWER STREET. CASES OF OVIARTOMY.

(Under the care of Dr. GRAILY HEWITT.)

(Continued from page 478.)

CASE XI. *Multilocular Cystic Tumour of Ovary: Considerable Adhesions: Ovariectomy: Recovery.* (Reported by Mr. A. P. GOULD, M.B.)—C. F., single, aged 40, had been under the care of Dr. Trouncer of Surbiton. She had had suppression of the catamenia for one year from cold at the age of 14. Since that time, she had been rather irregular. She was liable to oedema of the legs and feet. Eight months ago, after some exertion, she felt "rickel" in the side, and retention of urine occurred for one day. Six weeks later, she had a fall, and struck the side, soon after which the abdomen began to increase in size. On July 19th, 1874, she had menstruated last two months ago. She was emaciated. There was considerable oedema of the legs. The abdomen was much enlarged, more on the left than on the right side. Fluctuation was distinct, and limited to the area of dulness. The flanks were resonant. A vertical groove divided the tumour into two parts. The whole mass within the abdomen reached nearly to the ensiform cartilage.

On July 30th, ovariectomy was performed in the presence of Dr. Trouncer and others, Dr. John Williams assisting, together with Mr. B. P. Gould and Mr. D. Edwards. Chloroform was given by Mr. Meredith. The incision extended to the umbilicus. Adhesions intricately confused the recognition of the peritoneum, and three cysts were punctured, allowing each about one pint and a half of thick tenacious fluid to escape. The tumour was then found to be universally adherent over its anterior aspect, some of the adhesions above being very firm. The tumour, when finally turned out, was found to proceed from the right ovary, its pedicle being a broad one. An artery as large

as the radial was seen in it after it was cut through. The tumour was made up of a very large number of cysts; one was as large as a coconut. The pedicle was transfixed, tied in two portions, and secured externally by Dr. Graily Hewitt's gutta-percha clamp.

The progress of the case was good. The temperature once reached 100 deg. on the evening of the second day after operation; but, on all other days, below, or about 99 deg. The pulse never exceeded 96. The pedicle ligatures came away on the eighth day; the last suture was removed on the ninth day. On August 27th, the patient was discharged, cured.

Much comfort was given in this case by carefully bandaging both legs from the feet upwards, and slightly raising them.

CASE XII. Unilocular Large Cyst of Ovary: Three or Four Small Cysts: Muscular Coat to Principal Cyst: Ovariectomy: Recovery (Reported by Mr. D. EDWARDS).—J. E., aged 20, single, had been under the care of Dr. W. Ward Carr of Blackheath. She had good health until two years ago, when a tumour was noticed low down on the left side of the abdomen. A year ago, her breathing became embarrassed, the abdomen gradually increasing in size. Menstruation became more scanty than formerly, and ceased two months ago. There had been emaciation latterly. On examination, on October 15th, 1874, the abdomen was found to be much enlarged, pretty equally so, but more on the left side. Fluctuation was very distinct over the anterior aspect; the flanks were clear on percussion. Vaginal examination showed that the uterus was small; the os was close to the pubic symphysis; the fundus embedded in a soft tumour (the ovarian cyst).

On October 27th, 1874, ovariectomy was performed. Mr. R. Edwards gave chloroform. Dr. John Williams assisted in the operation; also Mr. Markham Skerritt and Mr. D. Edwards. The abdomen was thickly covered with fat. The incision made was three inches in length. There were no adhesions. Seventeen pints and a half of a very thin clear fluid were removed through the trocar, and the cyst was drawn out. The pedicle proceeded from the right side, and was very broad. It was transfixed, and tied, with the intention of fixing it externally; but it proved not long enough. The first ligature slipped a little in this attempt, and it was again tied lower down, cut short, and dropped. The cyst was a large simple cyst; at its base were three or four other cysts of the size of small nuts. Externally, the cyst had a quite distinct muscular envelope, which was one-eighth of an inch thick when contracted. This contraction excited attention directly afterwards, from the internal surface being thrown into folds, like the convolutions of the brain. Dr. Williams found muscular fibres in this envelope, which was, doubtless, derived from the posterior layer of the broad ligament drawn up and spread over this cyst. The subsequent history was favourable. There were no bad symptoms. The temperature was generally about 99.5 deg. The deep sutures were removed on the eighth day. On November 23rd, she was discharged, cured.]

CASE XIII. Multilocular Ovarian Cystic Tumour: Ovariectomy: Acute Rheumatism a Fortnight after Operation: Recovery (Reported by Dr. MARKHAM SKERRITT).—E. G., aged 36, single, had had pretty good health. She was of dark complexion. Menstruation of late had been rather too frequent. She had had rheumatic fever. The abdomen was first noticed to be enlarged five months ago, when also it became painful. Morning sickness and giddiness were also observed. The abdomen was now (December 5th, 1874) enlarged and globular; the umbilicus was depressed. A tumour, elastic, non-fluctuating, consisting evidently of large cysts, extended to three fingers' breadth above the umbilicus. The greatest measurement round the abdomen was 39¾ inches.

On December 8th, 1874, ovariectomy was performed; Mr. R. Edwards giving chloroform; Dr. Williams, Dr. Skerritt, and Mr. D. Edwards, assisting in the operation. The abdominal wall was found to be enormously thickly covered with fat, quite two inches in thickness. The incision did not extend above the umbilicus. No adhesions were found; but the right broad ligament was drawn upwards to such an extent, that it covered the right aspect of the tumour, and gave the idea at first of the existence of adhesion to the pelvic brim. Several cysts were emptied of an opalescent fluid, one after the other being opened. Finally, the tumour was turned out, on which it was seen that the pelvis had been tightly packed by the growth of secondary thin walled cysts into the Douglas pouch. The pedicle was on the right side. It was transfixed, tied with whipcord, and fixed, externally to the wound, to a gutta-percha frame-clamp.

The final result was good; but the condition at times gave rise to anxiety. On the second day, an erythematous blush was noticed on the thighs; on the third evening, the temperature was 101.4 deg.; pulse, 120; on the fourth evening, temperature, 102 deg.; pulse, 132. Next day, there was improvement. For the next ten days, there was satis-

factory progress, when, on the fourteenth day, the patient became attacked with acute rheumatism. The ligatures separated on the ninth day; the sutures were gradually removed one by one about the same time. The healing of the wound was slow. The rheumatic affection gave great trouble for nearly four weeks, the arms and shoulders being severely affected. At the end of a month, however, she was able to sit up, and was discharged, cured, seven weeks after operation.

CASE XIV. Ovarian Tumour, composed of one large and several smaller Cysts: Four previous tappings: Ovariectomy: Death on Third Day (Reported by Dr. SKERRITT).—R. B., aged 51, single, menstruated for the last time one year ago. The abdomen was first noticed to be enlarged three years ago. She had been tapped four times, the last time two months since. The patient had a worn expression; the digestive organs were not acting well; the breathing was short, and she did not sleep well. There was an abdominal tumour, globular in shape, reaching to one inch below the ensiform cartilage, presenting distinct fluctuation in all directions. After three weeks' preparation, the operation of ovariectomy was performed on December 21st, 1874. Mr. Downes gave chloroform. Dr. John Williams, Dr. Skerritt, and Mr. D. Edwards, assisted in the operation. The operation was borne badly, the respiration failing occasionally, especially just after emptying the cysts. The incision was at first short, but had finally to be extended above the umbilicus, in order to reach adhesions at that situation. There were no adhesions below, but very firm ones superiorly. The tumour consisted of one principal cyst containing a clear fluid, and several smaller cysts. The pedicle was long, about the size of a swan quill. The adhesion near the umbilicus was very firm, and was cut through by the actual cautery. The cyst-wall at this point presented a hard nodule, in which was found cretaceous deposit. The pedicle was tied with whipcord firmly; but, being small, it was not transfixed. The pedicle was secured to the frame of gutta-percha outside the wound. The insertion of the sutures produced an unusual amount of bleeding.

In the evening, it was found that there had been slight bleeding from the wound, but it ceased on being uncovered. The following morning, on further examination, it appeared that a part of the pedicle had slipped from the ligature, and it was then transfixed and retied; but no further hæmorrhage had occurred. On December 23rd (the third day), the patient had slept badly; a good deal of pain at the epigastrium; the temperature was 101.2 deg., and the pulse 128. The exhaustion gradually increased, and death took place on December 24th, a few hours less than three days after the operation. The wound presented hardly any union; there was some formation of pus at the sutures internally; there was a small clot, of the size of a walnut, in the pelvis, and also a small quantity of reddish serosity. The orifices of some of the vessels in the pedicle had become retracted below the point where the ligature was placed. The right ventricle of the heart was found to have excessively thin walls, and to be enlarged; the walls of the left ventricle showed signs of fatty degeneration. The lungs were congested inferiorly; a patch about one inch square in the lower lobe of the right lung was in a state of incipient gangrene. The kidneys were small, and the cortical substance was atrophied; cysts were evident on the surface of one kidney.

The death of the patient was due to a combination of causes: the weak heart, the slipping of the ligature, the cold weather (snow was then on the ground), and the disturbance of the wound necessitated by the occurrence of hæmorrhage. It is plain also that, however small the pedicle, it is better to transfix it before tying.

REMARKS.—In the present series of seven cases of ovariectomy, there were five recoveries and two deaths. In the total number of the reported cases at All Saints Institution (fourteen), there were nine recoveries and four deaths, or a percentage of recoveries of 64 per cent. The gutta-percha framework clamp mentioned in the above cases is a simple contrivance for maintaining the pedicle at the surface of the wound, which Dr. Graily Hewitt now employs, and finds admirably adapted for all cases in which the "clamp" method of dealing with the pedicle is selected.

WEST LONDON HOSPITAL.

EXTRAVASATION OF URINE: BOUTONNIERE OPERATION: RECOVERY.

(Under the care of Mr. TEEVAN.)

FREDERIC E., aged 14, was put under Mr. Teevan's care at the hospital by Dr. Atwood, at 5 P.M., June 4th, 1872.

History.—Seven years ago, whilst the lad was walking along the top of a fence, he slipped and fell astride the bar, severely injuring the perineum, so that a surgeon had to be sent for. After the accident, he made a very poor stream of urine, and latterly it only came in drops.

Present State.—When the patient was admitted, he was in a very emaciated condition, as he was only then recovering from a severe attack of acute rheumatism. The expression of his face was anxious, and he was crying on account of the pain he was suffering. The pulse was quick and feeble, and the tongue dry and brown. The body was covered with a profuse clammy perspiration. The hypogastric region was distended and dull on percussion. The scrotum and perineum were swollen, red, and brawny. No instrument of any kind could be passed; but, as fluctuation could be felt in the right ischio-rectal fossa, Mr. Teevan made an incision there, and let out some pus and about a pint of urine.

June 5th. The patient was comfortable; urine flowed freely from the wound. Redness had disappeared from the perineum.

June 12th. No instrument, soft or metallic, could be passed from the perineal wound into the bladder. There was much induration there, although urine was escaping freely. The stricture was found to commence three inches and a half from the meatus externus.

June 27th. The patient was very feverish; the tongue dry and brown; the perineum red and brawny. Chloroform having been administered, a No. 4 silver catheter was passed down the urethra as far as it would go, and Mr. Teevan laid open the canal for one inch above the stricture in order to search for the entrance into the contraction, but was unable to find it, and had to dissect bit by bit downwards and backwards till he arrived at the pervious portion of the urethra, when he was enabled to pass a flexible catheter into the bladder. The instrument was immediately withdrawn. On July 3rd, No. 3 silver was passed; on the 6th, No. 10 elastic, French gauge; on the 10th, No. 11; on the 13th, Nos. 12 and 13. The wound was nearly healed; most of the urine came through the penis.

July 20th, No. 14 was passed. The patient left the hospital on July 24th. A few days later, the wound was healed. For a month, the patient attended once a week to have a catheter passed, and then discontinued coming to the hospital. As a result of the patient's neglect, an urinary abscess formed in the perineum, and forced him to re-enter the hospital on December 5th. Mr. Teevan was unable to pass any instrument into the bladder, and opened the perineal abscess. In the course of ten days, the parts were in a favourable condition for instrumentation, and Mr. Teevan tried twice each week to pass different bougies, soft and metallic, without success. On February 18th, the lad was put under the influence of chloroform, and the boutonniere operation was again performed by Mr. Teevan. As the boy's urethra was very sensitive to the introduction of instruments, an elastic olivary catheter was left in the bladder. On February 26th, the instrument was removed, and passed with ease two days later; but all the anterior portion of the urethra was excessively sensitive to the passage of the catheter.

March 2nd. The lad suffered so much pain when Mr. Teevan was passing the catheter, that its further introduction was not persisted in. A week's rest did not improve the condition of the urethra, and every attempt to pass the catheter caused the lad excessive pain. Under these circumstances, Mr. Teevan determined to abandon the anterior portion of the urethra, and content himself with keeping the posterior part well open by passing a catheter from the perineum into the bladder, a procedure which caused the lad but slight annoyance. On March 12th, the patient left the hospital with a perineal fistula, through which he passed most of his urine.

February 8th, 1875. Ever since the last report, the lad has presented himself about once a month to have a soft olivary catheter passed through the perineal fistula into the bladder. The introduction of the instrument through the portion of the urethra posterior to the fistula is not attended with pain; but, if the catheter be passed down the anterior portion, the boy suffers much pain. He is in first rate health, and follows his occupation of paper-hanger. He can hold his urine for six hours with ease, and passes nearly all of it through the fistula, a few drops only escaping from the meatus externus.

Mr. Teevan remarked that when the boy was admitted, he departed from his usual practice of at once performing the boutonniere operation, as the lad was in so prostrate a condition, and contented himself with making an incision which sufficed not only to let out the pus, but also to give exit to the urine. The case showed the desirability of establishing a straight and free communication with the bladder, and demonstrating the patency of the opening by the frequent passage of a large olivary elastic catheter; for, before many days were over, the perineum became red and brawny, and the boutonniere had to be performed. The result was eminently satisfactory; for the boy left the hospital in good health, without any fistula, and with a repaired urethra, which permitted the introduction of No. 14, French gauge, with ease.

Unfortunately, the lad neglected to attend at the hospital, and in six months' time had to be re-admitted with a relapse, which necessitated

a second operation; the sequel of which was not so pleasing, as the boy recovered with a fistula, and there is, at present, no chance of its being closed, as the cicatrization of a perineum which has been so damaged with urinary abscesses has been attended with a tense and leathery condition of the integuments. But the closure of the fistula would not be desirable, even if it were possible; for that portion of the urethra which is anterior to the opening is so horribly sensitive to the introduction of instruments, as to entirely preclude all hope of the boy being able to pass a catheter for himself, or to permit a surgeon to do it. Some years hence, when the lad may possibly possess the requisite skill and determination to introduce an instrument upon himself, an attempt may be made to close the fistula if the state of the skin in the perineum be such as to permit its being made. For the present, however, the patient resembles the female in his manner of micturition, and would, if married, in all probability be sterile.

SELECTIONS FROM JOURNALS.

THERAPEUTICS.

ACTION OF SUBCUTANEOUS INJECTION OF MORPHIA.—Chouppe finds (*Gazette Médicale de Paris*, No. 35, 1874), as the result of a thousand experiments on himself, that the subcutaneous injection of morphia at the painful part produces its anæsthetic effect from two to two and a half minutes sooner than when it is made elsewhere. The pain ceases sooner than can be explained by supposing the morphia to act through the general system. A further proof of the local action of morphia is found in the use of concentrated solutions. While a weak solution of morphia in distilled water (1 in 150) produced severe pain at the point of injection, the injection of stronger solutions (1 in 50 and 1 in 30) was quite painless.

ACTION OF MERCURY AND IODINE.—According to Wreden (*Med. Neuigkeiten*, 1874; and *Allgemeine Med. Central-Zeitung*, No. 99, 1874), mercurial solutions act on iodised persons, and iodine solutions on mercurialised patients, twice or three times as quickly, whether used externally or internally, as when these medicines are given separately. He believes that this depends on the formation of biniodide of mercury in the tissues of the body. If a portion of the skin be rubbed with mercurial ointment and carefully washed after a few days, the inunction of iodine ointment produces the same symptoms of inflammation as arise from the inunction of biniodide of mercury. If a solution of corrosive sublimate (one or two grains in an ounce of distilled water) be dropped into the ear, no inflammation is produced, even though the application be repeated for several days; but it appears if, even after most careful cleansing, a solution of iodide of potassium (five grains to the ounce) be dropped in. If mercury have not been used, a solution of twenty or thirty grains of iodide of potassium is easily borne. Wreden has observed that, in patients who bore painting with iodine well, the skin, under the use of mercurial treatment by inunction, and even under the use of Zittmann's decoction, became exceedingly sensitive to iodine. He also remarks that the internal use of iodide of potassium by patients subjected to an energetic course of mercurial inunction produces more or less gastro-intestinal irritation, which is not the case in the same persons when even much larger doses of the iodide are given.

PATHOLOGY.

CHOKED DISC.—At the New York Society of Neurology and Electrology, on December 21st, 1874, Dr. E. G. Loring, jun., read a paper on the retinal circulation and the mechanical cause of choked disc. The first part of the paper detailed a series of experiments, from which it was concluded that the general circulation might be profoundly affected, as by drugs, electricity, or mechanical interference (as ligature of the arteries going to the head), and yet the circulation of the eye be uninfluenced, or but slightly so. Two alternatives were forcibly presented: either that the circulation of the eye is not a reflex of that of the brain, though derived directly from it; or, if it be so, that the influence exerted on the circulation of the brain by certain agents is very much less than hitherto supposed. From the similarity of the physical conditions and arrangement of the circulation of the eye and that of the brain, the question was raised whether there was any pulsation of the cerebral arteries; and reasons were given for inferring that, as there is none in the eye-arteries, there ought, by analogy, to be very little or none in the cerebral. The mechanical cause of choked disc was next considered. Von Graefe's theory of its production by increased intracranial pressure, Benedikt's hypothesis of a neuro-paralytic origin, and Schwalbe-Schmidt's that it was attributable to the passage of fluid from the arach-

noid space between the outer and inner sheaths of the optic nerve, were mentioned and discussed. The conclusion was that Graefe's explanation is insufficient, as is that of Schwalbe-Schmidt, and that that of Benedikt is the least assailable, perhaps because the least demonstrable. Dr. H. D. Noyes said that the theory of extension of fluid from the brain was not substantiated, but most necropsies showed fluid at the ocular but not at the cerebral end of the nerve. As the nerve approaches the eye, its circulation is increased by the accession of vessels, and around its entrance into the ball a vascular ring is formed. The nerve can only find room for expansion in a longitudinal direction. Caution is necessary in deducing cerebral conditions from examination of the ocular end of the optic nerve. Dr. R. H. Derby thought that the unreliability of the ophthalmoscope in the diagnosis of cerebral hyperemia or anemia was conclusively proved. Dr. Knapp remarked that there was a distinction between two forms of choked disc: that from neuritis descendens, with inflammatory action in the nerve or sheath, and distinct elevation of the disc, and that where fluid existed between the layers of the optic sheath. Blood might sometimes ooze from the brain through the intervaginal space into the eye. He believed that, with few exceptions, neuro-retinitis pointed to cerebral disease. Dr. Dalton considered the absence of arterial pulse in the eye as a remarkable fact, and the pulsation in the veins under abnormal conditions as still more incomprehensible. We might, perhaps, explain the non-pulsation of the arteries, but not that of the veins.

PHYSIOLOGY.

THE ACTION OF AMMONIA ON THE ANIMAL ORGANISM.—Lange writes on this subject, in a paper published in the *Archiv für Experimentelle Pathol. und Pharmak.*, 1874. He has endeavoured to determine whether, after the administration of ammoniacal salts, ammonia is eliminated in the gaseous state by the lungs, what relation exists between the blood and ammonia, and how ammonia is eliminated by other ways. He has also made experiments in order to ascertain whether the remote and general action of the different salts of ammonia has characters in common. To determine the question of elimination by the lungs, he made animals breathe through an apparatus containing sulphuric acid, which was afterwards tested with soda and Nessler's reagent. He could not on any occasion find ammonia in the expired air. A peculiar relation appears to exist between blood and ammonia. The author's experiments show that the blood of healthy animals, tested for free ammonia by Strauch and Kühne's method, gives off ammonia at a temperature of 60 to 65 cent. (140 to 149 Fahr.); and that living and dead blood behave differently towards carbonate of ammonia. When carbonate of ammonia was added to blood taken from the dead body of an animal, ammonia was given off at a temperature of 40 to 45 cent. (104 to 113 Fahr.); but when blood was taken from a living animal was treated in the same way, a temperature of 80 to 90 cent. (176 to 194 Fahr.) was required for the extrication of ammonia. The endeavours to arrive at sufficient data regarding the destiny of ammonia in the blood were frustrated by extraordinary difficulties. On this point, Lange expects light to be thrown by Schultzen's researches on the synthesis of urea in the blood. With regard to the physiological action of ammonia-salts, Lange arrives at the conclusion that they have a common character, differing one from another only in intensity. He regards chloride of ammonium as the most poisonous salt. The symptoms produced in the nervous system consist in more or less violent paroxysm of convulsions, affecting all the voluntary muscles, and, when the dose is very large, producing death. The respiration is much affected. Immediately after the injection of ammonia into the veins, the breathing is arrested for some seconds; then, after moderate doses, there is an enormous acceleration of the respiration. With larger doses, the acceleration is preceded by a marked retardation. No reduction in frequency nor dyspnoea is produced by division of the vagus after acceleration of the breathing has set in. The blood-pressure at first falls, but then suddenly rises; and then gradually sinks again, until in a time, varying from one to five minutes, it is reduced below the normal. Division of the cervical spinal cord produces no change in the phenomena. The frequency of the pulse follows the changes in the blood-pressure; it increases with it up to a certain limit. Increase of the dose of ammonia beyond a certain quantity produces a rather rapid fall of the blood-pressure, and arrest of the heart's action. Lange gives the following explanation of these phenomena. The salts of ammonia produce convulsions, having their origin in the spinal cord; the respiratory centres in the medulla oblongata become abnormally irritated, and transmit an excess of irritation to the ends of the vagi in the lungs (producing the brief arrest of respiration). The increase in the blood-pressure has nothing to do with implication of the vaso-motor centre in the medulla; it is independent of the convulsions.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, APRIL 10TH, 1875.

THE QUALIFICATIONS OF HOSPITAL MEDICAL OFFICERS.

IN a late impression of the JOURNAL, we had occasion to refer to the proposal made by Mr. Semon to the Governors of the Bradford Infirmary, that they should so amend their rules as to allow general practitioners to offer their services in the care and treatment of the medical patients of the hospital. Since that time, the matter seems to have excited considerable interest in the town, numerous letters having appeared in the local prints, which have also in other ways commented upon it. Our attention has been called to a communicated article, and also to a leader, in the *Bradford Observer*, the leading paper of the town, in which the subject is carefully and more or less exhaustively considered. As we understand the question, the following is the position of affairs.

The rules of the infirmary allow four general practitioners to take charge of the surgical patients of the hospital, but two pure physicians are required for the medical patients; and while the surgical staff is always easily maintained at its full complement, great difficulty has been for some years experienced in finding physicians. It is contended by Mr. Semon, that the restriction regarding the medical cases is not required, as there is no more apparent necessity that medical cases should be attended by pure physicians than that surgical patients should have the services of pure surgeons. Further, it is stated that, since the foundation of the hospital in 1825, the rule has been far more frequently broken than kept. The rule, as is generally the case in public hospitals, seems to have been drawn up to suit the state of things in existence when the hospital was founded; and as there were in 1825 three pure physicians in Bradford—and, by the way, the medical staff originally consisted of three physicians and not two as at present—the clause was naturally enough appended to the rule appointing the physicians, that no person could be elected to or retain the office of physician who was in practice as a general practitioner. Until 1845, when Dr. Outhwaite left the town, things seem to have worked smoothly enough, Dr. Mac Turk and himself having carefully attended to the medical cases of the hospital. But since that time a large number of gentlemen, who are named in Mr. Semon's circular, seem to have come to and gone from Bradford, after finding that there was not in the town any demand for the services of two pure physicians. So noticeably was this the case, that even during Dr. Mac Turk's lifetime, and when his large private consulting practice prevented his giving so much of his valuable time as formerly to the care of the infirmary patients, the board of management found it necessary to appoint two paid general practitioners to attend to the medical out-patients. Since then, several physicians have been attached to the infirmary, no fewer than four having been appointed in the last four or five years; and at the present time only one physician on the staff is left to do among the medical and more numerous patients of the hospital what four general practitioners do for the surgical and less numerous. Mr. Semon's question to the Governors is: Why should this unsatisfactory state of things be allowed

to continue? He proposes to so amend the rule regarding the appointment of physicians, as to allow general practitioners to offer their services to the infirmary board, urging, in addition to what has been said, that general practitioners are eligible to do purely medical work at the Fever Hospital, where the arrangement works well.

As regards the particular case of the Bradford Infirmary, no doubt the governors may be trusted to do their own business in the way they think best. Our sole interest in the matter is that the institution should perform in the most efficient manner those services which are the special glory of all infirmaries. But we have been led to inquire into this case specially, because the procedure of this infirmary, and the difficulties experienced in Bradford, are part of a great question which is of general interest to the public and the medical profession: we mean the appointment of physicians to hospitals in general. On this point the greatest diversity of procedure seems to prevail. Some infirmaries follow the course adopted at Bradford, and restrict the holders of physicianships to the practice of pure physic. Others allow general practitioners to be appointed with or without a restriction as to practising pharmacy: which, however, usually holds equally in the case of the surgeons. And yet others draw no distinction between the gentlemen in charge of the medical and those in charge of the surgical cases, appointing simply a certain number of honorary medical officers whose duty is to be responsible for cases medical or surgical, as they are admitted. And it is a curious fact that, with the exception of medical schools, where for obvious reasons pure physicians—and pure surgeons also—tend to become attached to the hospitals, those infirmaries which experience the difficulty felt at Bradford of supplying their patients with the services of physicians are precisely those which, like it, restrict their physicians to the practice of pure medicine. Taking some of the Yorkshire infirmaries near Bradford, for example, we find that in Huddersfield the rules require the appointment of two pure physicians, but at the present moment there is, as there has been for some time past, only one on the staff. The same hospital has no difficulty whatever in finding five gentlemen, general practitioners, to do the surgical work of the institution. In Halifax again, though the rules allow the appointment of three pure physicians, for some time there was only one, and now there are no more than two on the staff, one of them being the medical officer of health for the district, the tenure of whose office depends on his not doing private practice. The case of Halifax, indeed, seems to us to be the *reductio ad absurdum* of the system pursued. For it will surely not be denied that one of the main uses of having a physician in a town is, that his colleagues may from time to time have the benefit of his advice and assistance in cases where they experience difficulty. And yet in this instance the gentleman in question is appointed just because he cannot take private practice, and can, therefore, neither be of any assistance to his medical brethren, nor yet afford to infirmary patients the advantage of that extended experience which a gentleman must have who is in the constant habit of dealing with private as well as with public cases. It will not, of course, be supposed that our remarks have any personal reference, it being well known and recognised both by the profession and the public that the gentleman in question possesses qualifications for his work of a very high order indeed; but the system under which he is appointed seems a bad one, and detrimental to the interests of the general public, of the profession, and of the infirmary patients themselves. Besides this, the rule works so badly, that, though three physicians are arranged for, only two are obtained even by this device. In Northampton, the same difficulty has been experienced, and from the same reason. Though here the rule only requires the candidate for physicianship to be a graduate in medicine of an university, it has always been interpreted as preventing general practitioners from holding the office; and the consequence is, that, while two physicians are required, one of the two is at the present moment a gentleman who has

retired from private practice. That is to say, in the case of Halifax, a physician is appointed who cannot do any private practice, and, in the case of Northampton, one who has retired from it. Could anything be conceived more utterly condemnatory of the system which produces such appointments?

Similar instances of anomaly and difficulty induced by this cause might, no doubt, be multiplied. But the point we are chiefly interested in insisting on is, that the difficulty of finding physicians is non-existent where the rules are different. Thus, at Portsmouth and Preston, where eight and six honorary medical officers respectively are required, the staffs are full. In Chester, Shrewsbury, Norwich, and Taunton, where the rules in each case require three physicians, but allow general practitioners to hold the office, there is no difficulty in finding men, and the staffs of all these hospitals are at the present moment complete. And so in numerous other cases, where two or one physician-general-practitioner is required, the men come forward. Not a single instance, for example, has come under our notice in which any difficulty in filling the post of physician coexists with the throwing of the office open to practitioners, and this must surely be taken as a strong fact in favour of Mr. Semon's proposed change at Bradford. In addition to this consideration, we are informed that a large proportion, in fact the great majority, of the medical practitioners in the town, including some of the leading men on the infirmary staff, are in favour of the proposed change. If this be really so—and there ought to be no difficulty in finding out the state of medical opinion on such a point—the governors of the Bradford Infirmary ought to have an easy task before them.

Of course, in the remarks which we have made, we would not be understood as saying anything against the gentlemen who hold these appointments, nor against the appointment to public hospitals of pure physicians when such men offer themselves. Still less do we deny that, when medical men devote their whole energies to any branch of medicine, they are likely to attain to special skill and eminence in their own department. The whole history of professional work points to the contrary conclusion. But the question may very fairly be raised whether the method pursued at Bradford of from the first restricting men to special work, and still more to special fees, is the best means of evoking the best talent of the profession in special directions. At least we know that, in some of the most famous medical centres in the country, the opposite course is followed, and with the best results. In none of the Scotch medical schools, for instance, not even in Edinburgh itself, are the physicians prevented from doing what form of private practice they think proper; and yet Edinburgh has produced some of the most eminent names in the whole medical profession; besides that her graduates hold some of the chief positions in various parts of the country. No doubt, in towns where the custom prevails, more or less specialisation of function is sooner or later attained, and many of the physicians who begin as practitioners become pure consultants afterwards—a position to which they never might have risen had the other course of procedure obtained. In fact, this seems the fairer plan, since it allows to poor men, who may prove their competence for the position, equal facilities with richer competitors against whom they would otherwise have had far less chance of succeeding. The best men ought to come to the front, and that system is best which encourages the best men to do so. Another consideration in favour of this view is, that the character of medical education all over the country has materially advanced of late years. There is, in fact, no guarantee, because a man calls himself a physician, that he is in any respect more able or more competent than his neighbour who is a general practitioner. He may be so, and no doubt often is so; but things are commonly enough reversed, particularly in provincial towns; and, in point of fact, we frequently find two men practising side by side, the one as a physician, the other as a general practitioner,

whose course of study has been the same, whose qualifications are the same, and whose relative positions have been determined by the accident of dissimilar circumstances or disproportionate means. The day has, at any rate, long gone by when a surgeon occupied a sphere of culture and education no higher than his barber-partner, and both were quite unfit company for the scholarly and accomplished gentleman who was the physician to a hospital. We shall await the issue of the question now raised in the Bradford Infirmary with considerable interest, partly from its local, but chiefly from its general interest; but, whatever the result may be, we trust that the discussion may further the work and increase the usefulness of that and other kindred institutions.

PROVIDENT INSTITUTIONS AND HOSPITALS.

II.—OUT-PATIENT REFORM.

WE now pass on to consider the system of management and work of some of the most important provident dispensaries. It would be almost impossible, if the space at our disposal were adequate, to give a description of all, or nearly all, the various dispensaries which have some portion of the provident scheme in connection with their management. We shall, therefore, content ourselves with taking as our models the Royal Victoria Dispensary, Northampton, and the District Provident Dispensaries, Manchester; because the former is, we believe, the oldest in the kingdom, many of the more recent provident dispensaries being founded upon the basis laid down in its scheme of management; and the latter embrace so many novel and excellent features that our articles would be incomplete without an account of their system.

The Northampton Dispensary was founded in the year 1845. A building was purchased for £1,000, which sum was raised in donations, and the work has been carried on in the same premises to the present day. Its objects were declared to be "to enable the working classes to ensure for themselves and their families efficient medical advice and medicine during illness, by their own personal payments, with the assistance of contributions from the more opulent". That is to say, the subscribers to the dispensary, as apart from its members, are the governors; they elect from amongst themselves a committee of management; and their subscriptions, which amounted in the year 1873 to £199, are devoted to the payment of half the midwifery fees and all the expenses attending the management of the institution. A special feature in this dispensary is that the whole of the money subscribed by the poor or free members, after deducting the expense of drugs and medical appliances, is divided amongst the medical staff in proportion to the number of cases attended by them.

The persons for whose benefit this dispensary was founded are called free members, and are confined to "working men and servants, their wives and families"; but any person in receipt of parish relief, or who is proved to be able to pay for medical attendance, is refused admission to the benefits of the institution. That is to say, the only persons who are accepted as members, are "all artisans working as journeymen, and labourers, without reference to the rate of wages they may receive"; but "all persons acting as foremen, or earning their living by keeping a shop, and all persons keeping beer-shops or public-houses", are refused admission. Every free member has to pay one penny a week if over, and a halfpenny a week if under, fourteen years of age; twopence a week is the sum demanded for a man and his wife and their children under fourteen years of age; and, in the first case, an entrance fee of six shillings, and in the last of one shilling, has to be paid in addition. Servants pay five shillings a-year in half yearly payments. All payments are made in advance, and a fine of one penny weekly is inflicted for every week in arrear. In addition, the wives of members subscribing twopence per week, are entitled to attendance during their confinement, on payment of five shillings three months previously, provided they have been members at least six

months. An additional fee of five shillings is added from the subscriptions of the governors, so that the medical officer gets ten shillings for each case he attends.

There were at first six medical officers appointed; but, owing to much disagreement and jealousy arising between them, this number was eventually reduced to three, who have for years worked together most amicably and satisfactorily. The balance of the contributions of the free members available for the payment of the medical staff is divided amongst them, in proportion to the number of members who appear on the register as attached, by their own choice, to the respective medical officers, the numbers in each being quite unlimited. No fewer than 46,101 people were seen in the year 1873 by the medical staff of this institution, who received £1,507 as payment for their services; and 32,852 prescriptions were made up.

Two questions necessarily arise: How has this scheme worked? and what are the opinions of the profession at Northampton in regard to it? Mr. Becke, the Honorary Secretary, states: "With upwards of six thousand members on the books, we do not receive complaints of more than five or six families yearly being in circumstances such as to enable them to pay for relief; and these families are always expelled." Great care appears to be taken to prevent abuse, and the plan pursued is worthy of record. A book containing the name, address, and occupation of every person applying for admission is laid before the Committee every week. This book lies open on the table all the week, and the medical men are invited to inspect it. If the name of the applicant be known to any of the Committee, the word "proper" is written in a column kept for the purpose; or, if the applicant be known to be ineligible, some observation of this kind is written, "Is a foreman", "a shopkeeper", "has house-property", and so forth; or private information may be sent to the Secretary. The list is read over to the Committee at each meeting; and those cases which "require investigation are handed to the different members of the Committee: each committee-man taking a district, and making personal inquiries". On the following week, the whole of these names, with the observations and reports of the inspectors, are read; and each application is decided on its merits, the name of the committee-man making the report being entered in the book.

Mr. Becke adds, "during fourteen years I have not had more than fifty cases brought before me in which it was alleged that the members were able to pay for medical advice, and generally speaking these persons have been induced to withdraw." He also says that many small shopkeepers have been refused, where it would have been a great charity to admit them; and "I have known persons refused relief at this institution as being able to pay for medical aid in the ordinary manner, go without advice, until they could get a ticket to admit them into the Infirmary". Here we have direct evidence, from a gentleman of large experience, of the abuse to which hospitals are subjected under their present system of management. Fancy it being possible for a man to obtain admission to a charitable institution like a hospital, whose income was considered too large to entitle him to a share of the benefits of a provident institution like this, for which he would have to pay! On the other hand, we are informed that the majority of the profession at Northampton are strongly opposed to this dispensary on the following grounds, all of which are alleged to be true.

1. "That the dispensary is not open to all the medical men of the town who would be willing to join it.
2. "That the appointment of the medical officers is practically vested in the hands of two or three gentlemen. The present three medical officers are all quite recent arrivals in the town compared with several older resident members of the profession, whose claims to the post have been persistently ignored.
3. "That the practices of several medical men in the town have sensibly decreased in value since the establishment of the dispensary.

proving that persons who heretofore have paid for private medical attendance are now improperly admitted into the dispensary.

[The following three cases, all members of the dispensary at the present time, have been sent to us in confirmation of this statement: *a.* Mrs. W., keeps a beershop in W. street, occupies her own house and owns several others. *b.* G. M., a sexton, lives in his own house and owns the next. *c.* S., lives in his own house and owns another in B. street.]

4. "That the work cannot properly be done by three medical men, and that, therefore, especially during the last few years, these three medical officers have in many cases employed an assistant to do their work for them. When the large salaries received by the staff are borne in mind, and the sum probably paid to such assistant is considered, they are of opinion that an insight is gained into one of the greatest abuses of this dispensary."

We must leave our readers to judge these opposite statements side by side, to form their own opinion of the amount of abuse which is likely to exist, and to compare it with the great public good this dispensary undoubtedly does. For our own part, we cannot but regard as satisfactory the fact that the medical staff receive on an average not less than six shillings per family *per annum* for their services. There is one point which, as a profession, we ought not to overlook, and it has been clearly set forth by Mr. Becke in his pamphlet, to which we made reference in our former article. It is this—the principle of co-operation is spreading everywhere among the working-classes, and if we do not promote Provident Dispensaries based upon principles which are equitable to the medical men as well as to the members, the artisans will assuredly set on foot "medical institutes" (as has already been done in several places), in which the terms of membership are much less strict than they are at the Provident Dispensaries, so that they admit tradesmen, foremen, and others of a superior grade; and in which the committee, being wholly composed of working men, is not a pleasant master for an educated gentleman to serve under. It is our true policy to put ourselves at the head of the provident movement, and thus both to amend the club system, and to anticipate the establishment of such "medical institutes". We must leave to a future paper the description we purpose giving of the Manchester dispensaries.

THE *conversazione* of the Quekett Microscopical Club will take place at University College on the 16th instant, at 8 o'clock.

The next meeting of the American Medical Association will be held at Louisville, Kentucky, on the first Tuesday in May.

ALDERMAN JESSOP of Sheffield has given £12,000 towards the building and furnishing of another hospital for women in Sheffield.

DR. C. THEODORE WILLIAMS has been appointed by the Council of the Medical Society of London to deliver the Lettsomian Lectures in January 1876.

THE annual dinner of the Chairman and Committee of Management of King's College Hospital will take place in the College on the 14th instant, at a quarter before seven. H.R.H. the Duke of Cambridge, President of the institution, will take the chair.

THE statement recently made by a medical paper, that the General Medical Council will meet on June 10th, is inaccurate. No date has yet been fixed for that meeting. In all probability it will occur considerably later than the day indicated.

HER MAJESTY the Queen has expressed her personal sense of the long and faithful services of Dr. Minter, Inspector of Hospitals and Fleets, by appointing him to be Honorary Physician to the Queen upon his retirement from the Royal Navy.

WE hear that the Croonian Lecture of the Royal Society this year will be delivered by Dr. Ferrier. It will include an account of some

further experimental results of the investigations on the Localisation of the Functions of the Brain, by which he has already greatly distinguished himself and enriched physiological knowledge.

GOOD NEWS FOR LONDON CHARITIES.

ANONYMOUS donations of £1,000 have not ceased with the death of Mr. Attwood. We hear that, on Monday last, a gentleman walked into the London Hospital, and said he wished to give a small donation. On entering the Secretary's office, he handed a £1,000 note to the House-Governor, and said he wished it acknowledged from J. A good many Secretaries will probably scan unknown visitors for some time to come with peculiar interest.

THE HEALTH OF FOLKESTONE.

THERE can, we think, be little question that Lord Robert Montagu's statements in the House of Commons on Tuesday night, in reference to the health of Folkestone, considerably overshot the mark. First, with regard to the death-rate, his lordship said that the Registrar-General in August last placed Folkestone, not in the first or second category, but in the third, with a death-rate of 23 per 1,000. The registrar really placed Folkestone, for the second quarter of last year, in the category of places having a death-rate of from 20 to 23 per 1,000; that of Folkestone being the merest fraction over 20. The death-rate for the whole year was but 18.1, and for ten years ending 1870, 16.4 per 1,000. There has been no decennial average taken since 1870; but we have no reason to believe that a fresh one would place Folkestone in any lower position. In the quarter to which his lordship refers, an unusual number of visitors died; but it is stated that many of them had but just reached Folkestone after wintering abroad. The local officer of health (Mr. Bateman) states that, during the two years that he has held the position, the town has been remarkably free from fever. In 1874, there were but two deaths from fever and two from scarlatina; in 1873 none; and at the present time he is not aware of the existence of any case of fever at all. The "fever-dens" to which reference was made are buildings such as call for condemnation, but it is somewhat remarkable that no fever has occurred in them for some years, and the registrar has no recollection of a death from fever there at any time. The sewerage arrangements are good; no backwash of sewage on the beach can occur, and the sewers are well ventilated. Altogether, we have every reason to believe that Folkestone may still challenge comparison with any town in England.

THE LATE COUNT DE JARNAC.

WE have received the following from Dr. A. Vintras, the able and accomplished Physician to the French Embassy, London.

"A report having been spread that the late French ambassador, the Comte de Jarnac, was bled at the commencement of his illness, this has led to the supposition that blood was taken from the arm; and, as such was not the case, it may dispel an erroneous idea from the minds of his friends if I briefly state the actual facts. The Count was attacked with pleurisy supervening upon dry asthma, from which he had been suffering since the beginning of the year, without having submitted to any treatment. On my first seeing him, I at once applied four leeches to relieve the local pain, which was very considerable, and great relief was afforded by them. The notion that such a small abstraction of blood at the onset of the disease could be other than beneficial to the patient, cannot, I think, be entertained."

SOME STATISTICS OF ADULTERATION.

JUST now, while the working of the Adulteration Act of 1872 is under consideration, a table published in the *Chemical News* showing the "aggregate results" of the working of the Act in a good many places is of some interest. We gather from it that, notwithstanding the determination which is now being shown to "relax the severity of the Act", it has proved itself as capable of yielding no results at all as the warmest friend of the retail tradesman could desire. Thus, although 701 samples were analysed in the combined districts of Greenwich, Plumstead, and Woolwich, of which 84 were found to be adulterated, there were "no convictions". In South Staffordshire, 526 samples were analysed, of

which nearly one-half (251) were found to be adulterated, including 88 samples of milk and 137 samples of tea, without any conviction being obtained. So also in Wolverhampton, although 163 samples have been analysed with the result of finding 56 to be adulterated, there were no convictions; while in the neighbouring town of Birmingham the analysis of 163 samples, of which 101 proved to be adulterated, led to 38 convictions. It is impossible to doubt that the law might have as effectually been put into operation in one part of the Midland Counties as another; it is, therefore, evident that in any amendment of the law the authorities should be required to carry it into effect. The use of a public analyst is not very apparent, if those to whom he reports make no efforts to protect the public from the frauds which he discovers. Among the London districts, we find St. George's, Hanover Square, remarkable for a similar inactivity; 151 examinations of food showed adulteration in 51 instances, but there were "no convictions". The greatest vigour appears to have been shown in Somerset, where 2,216 samples were examined, of which 845 were found to be adulterated, and 520 convictions were obtained under the Act.

SHAM SANITATION.

It may be worth while for the members of the House of Commons, in considering Mr. Sclater-Booth's Bill for consolidating and amending the Public Health Acts, to bear in mind that a main cause of the failure of Mr. Stansfeld's Public Health Act of 1872 was his refusal to provide adequate areas with suitable authorities and efficient officers. Without again travelling over this ground, we may point out that our predictions of failure have been precisely fulfilled; and that at this moment there exists all over the country a complete chaos of authorities, areas, and officers. Where there has occurred a voluntary fusion of districts to form an adequate area, good results have been attained, as by Dr. Bond in Gloucestershire, Dr. Child in Oxfordshire, Mr. Haviland in Northampton, Dr. Ogle, Dr. Syson, Dr. Baylis, and others, each in their respective districts. But there exists a great class of underpaid medical officers serving burlesque boards of health, whose sole object is to comply with the forms of, perhaps, the most clumsy Act of Parliament framed in modern times, and altogether to evade real sanitary work. We find a singular confirmation of this fact in the preface to a little book on *Water Analysis*, recently published by Dr. C. B. Fox, a medical officer of much activity. He recognises the existence of this state of things, but expressly intimating that "it was *not* written for the instruction of *dummy* medical officers of health who receive £5 or £10 a-year as a salary, with the understanding that they are to do nothing". A recent reviewer, in noticing this passage, observes: "We fear that the existence of such sham health-officers, appointed not to execute but to evade the sanitary laws, is an undeniable fact. The tacit 'understanding' of which Dr. Fox speaks might, indeed, be difficult to prove. But when a gentleman accepts for such a sum duties which, if really performed, would engross, perhaps, half his time, it is but fair to infer that his functions are no less nominal than his salary. We could name a little town where, behind every dwelling, the cesspool and the draw-well stand in amicable propinquity, separated by at most six yards of gravel, shingle, and chalk. The 'conscript fathers' of that town have appointed a health-officer at £10 a-year, and we are certain that any display of conscientiousness or vigour on his part would lead to his dismissal at the earliest opportunity."

VALUE OF VACCINATION.

THE following vaccination statistics have been compiled from the books of the Montreal General Hospital. During the past twelve months, fifty-five unvaccinated persons were admitted into the small-pox wards. All of them except five have had the confluent form of the disease—i. e., the serious form; and out of the fifty-five who were admitted, twenty-eight died, showing a mortality in the unvaccinated of over 50 per cent. On the other hand, among those who had been once vaccinated and had two good marks on the arm, there were only four deaths. Only seven had more than two good marks, and those seven had the mildest form of the disease, and made a rapid recovery.

Only two cases were admitted during the last twelve months who had been successfully revaccinated; and in them the disease was so mild that they might have been permitted, except as a precautionary measure, to follow their ordinary avocations. Thus, in the unvaccinated, the mortality was over 50 per cent.; among those who had been properly vaccinated in their infancy, but who had neglected to be revaccinated, there were only four deaths; while only two cases had been admitted where revaccination had been successfully performed, and they were of the mildest description. (*Ibid.*)

A PLEA FOR PARDON.

WE are very glad to hear that a petition is being numerously and influentially signed for the remission of the sentence of Mr. Edwin Peacock, lately sentenced to six months' imprisonment for maltreatment of a lying-in woman by removal of a portion of intestine protruding through a rent in the uterus. The circumstances are no doubt fresh in the memory of our readers, and we believe all will concur that the facts proved in this case were such as to fully warrant the immediate exercise of the prerogative of the Crown. We should be very slow to urge any plea in such a case, were it not that it is certain that there was no want of professional skill, nor any neglect or remissness of duty, still less any fault of intention; but that the circumstances were due to an error of judgment under conditions of great difficulty and excitement.

OBSTETRICAL SOCIETY OF LONDON.

At the meeting on Wednesday evening, which was densely thronged by practitioners from all parts of the kingdom, Mr. Spencer Wells opened the discussion on the Relation of Puerperal Fever to the Infective Diseases and Pyæmia in a very able and lucid address, in which he stated that his object was to elicit rather than to impart information. A letter from Dr. Matthews Duncan was read, in which he expressed his dissent from the late prosecution of midwives for disseminating puerperal fever, and stated that he thought it preposterous to expect practitioners to give up their practice on this account, affirming that strict cleanliness of person and changing the clothes was sufficient precaution to take. Professor Leishman of Glasgow said that it was frequently affirmed that pyæmia and puerperal fever were likely to be engendered by decomposing animal matters, and that students who dissected were liable to convey this infection; but, if this were so certain and so frequent, we should have far more puerperal fever in the practice of students than actually occurred. Dr. Newman of Stamford concluded, from observations made during twenty years of large general and hospital practice, that there was no such thing as a distinct puerperal fever so-called, but that there was always a direct or indirect communication of contagion of some definite poison. In some instances, mental disturbance seemed to play an important part in the production of puerperal fever, or at least in rendering the patients very susceptible to the development of febrile disturbance. Dr. Braxton Hicks referred to a paper of his published in the twelfth volume of the *Obstetrical Transactions*, wherein he had recorded the result of eighty-nine cases observed by himself, showing that the contagion of scarlet fever exercised a marked influence in the production of puerperal fever. Mr. Jonathan Hutchinson considered that there was no such thing as a specific poison which would produce puerperal fever, but that this might be caused by a number of different maladies. The term surgical fever was even more vague than that of puerperal fever. We ought to attempt to define the terms we use when we speak of pyæmia, septicæmia, or specific disease. Erysipelas itself was not a specific fever, but only a local condition. The term septicæmia ought to be employed only when patients were poisoned by the disintegration of their own tissues. Pyæmia was produced by inflammation of the patient's own tissues. Dr. B. W. Richardson thought we should bear in mind the condition of the patient after delivery. The blood was in a peculiar condition, the fibrin being in excess, the salts diminished. There was also a nervous condition to take into consideration; the conditions being similar to those met with in febrile disturbance. From experi-

ments and observation, he was unable to declare that there was a special poison creating puerperal fever. There were very distinct forms of fever: in one case, pure simple surgical fever following delivery; in others, fever of a bilious remittent character, with symptoms of jaundice. In another class, there was a form of septicæmic poisoning, where there was exposure of the cellular tissue and poisoning immediately from the patient herself. In a fourth class, the poison was carried from without, as scarlatina, erysipelas, etc. As regarded the relation of bacteria and allied organic forms to the pyæmic process in the puerperal state, he considered the organic products as mere coincidences. The discussion was adjourned to the next meeting. We shall publish a full report next week.

ORIGIN OF TYPHOID.

THE following is taken from the Annual Report of the Medical Officer of Health for the Rural Sanitary District of Basford, and, as bearing upon the question of the origin of typhoid fever, about which much discussion has taken place, is of interest. It will be remembered that Professor Tyndall has publicly and emphatically endorsed the doctrine ably set forth by Dr. Budd of Bristol, that typhoid fever, like small-pox, can spread and occur only by propagation from one to another—in fact, cannot arise *de novo*. It is on this point that Mr. Whitgreave speaks to the following effect.

"My observations for many years have convinced me most thoroughly that Professor Tyndall is wrong. I speak strongly upon this subject, because, were he right, there would be little necessity to continue efforts to remove nuisances from the neighbourhood of human habitations. The only possibility of preventing typhoid fever would be excluding everybody from entering the district who might have it, and enforcing an edict that every one now living in the district must never go out of it, for fear they should go where typhoid fever is. Typhoid fever is certainly slightly infectious; and, if any water or food in the most minute degree contaminated with the discharge of a fever-patient gain entrance into the stomach of a healthy person, typhoid fever is almost quite certain to be the result. But, in addition to these means of the disease being propagated, it may begin at any time anew in a person who, being perhaps at the time in a low condition of health, becomes exposed to even inhaling the emanations of some fermenting (zymotic) nuisance. I will give an illustration. W. D., aged 16, of Ruddington, on October 24th went to see a fire at Bunny (where, however, there had been an isolated case of typhoid six months before). He remained away all night, and came home in the middle of the next afternoon. He was very cold and tired, having been all that time without food and his accustomed sleep. Just in front of his house, there were two untrapped gulleys communicating with a choked-up drain, which has since then been rebuilt. The boy soon became ill; had to take to his bed; said he had a 'bad cold'; but it proved to be an attack, beyond any doubt, of typhoid fever. Fortunately, under the treatment of Dr. Hall, he did not die. Disinfectants were used, the drains were attended to, and no other case occurred in the yard. If the disease were always created by contagion or infection, we should not have solitary cases cropping up in such distant parts and at such different dates of the year. The probabilities are, that we should have it in epidemics, which would be also endemic or local."

ETHER INTOXICATION.

THE *London Medical Record* of this week contains a translation of a paper by Dr. Ewald of Berlin on a case which, if not unique as he supposes it to be, must be of extreme rarity. It is that of a man aged 32, who was lately admitted into the Charité Hospital under Professor Frierichs, suffering from general debility and trembling of the muscles. On inquiry, it was found that he was notorious in Berlin for intoxicating himself with ether, his abuse of which had reduced him to his present miserable condition. He was originally temperate, and had been an university student, passing all his examinations with credit; he was, however, of a mystical turn of mind. Unfortunately, a little more than nine years ago, there fell into his hands a medico-popular treatise, in which the use and effects of ether used medicinally were described, and a glowing account was given of its effect in quickening the creative power of the mind. He procured about two or two and a half ounces of sulphuric ether, and inhaled it from a handkerchief; the result being to produce insensibility for about a quarter of an hour, during which time he

imagined that he lived for an indefinite time and travelled over whole worlds. This condition, however, he was not again able to induce in so high a degree. Becoming gradually more and more addicted to his habit, he no longer confined himself to indulging himself in his own room, but, with his etherised handkerchief before his face, he wandered through the streets, purchasing small quantities of ether at the druggists' shops, until at last he became so great a nuisance to them that many of them closed their doors against him. He was also turned out of his lodgings on account of the annoyance produced by the smell of his breath, and became a houseless wanderer, reduced in means and in health. In the hospital, there was no indication that his mind was affected; his memory was not impaired; his style of speaking was fluent. On one occasion, an attempt was made to produce complete anaesthesia. For this purpose, more than seven ounces were required; the ether being given by an inhaler, and loss being prevented by closing in the apparatus with cotton-wool. No sooner, however, was the inhalation stopped, than the state of insensibility passed off. He was then allowed to take the ether in his own way, by inhaling it from a handkerchief. Given in this way, it produced a stage of excitement, during which he danced about the room, talked nonsense, and appeared much pleased; but there was no true narcotism. It was not thought justifiable to subject him to other experiments with ether, as it was desirable to break through his habit. It is interesting, that his susceptibility to the action of cannabis Indica was not impaired. This drug was given as a substitute for ether; and on the first occasion, too large a dose having been given, the result was the production of phantasms, such as are induced by the smoking of haschisch.

AN EMINENT PHARMACEUTIST.

THE premature death of Mr. Daniel Hanbury, F.R.S., before completing his fiftieth year, is announced. Some words of commemoration in these pages are due to a man whose life was largely spent in studies ancillary to the practice of therapeutics, and who afforded a bright example of intellectual activity, and personal modesty and worth. His latest great work, the *Pharmacopæia*, which he published last year in company with Professor Flückiger, we noticed at the time as a monument of skilful erudition and hard work. Mr. Hanbury was a honour to the class to which he belonged; the annals of British pharmacy in this country are associated with no worthier name. He was greatly respected by the many medical men to whom he was personally known. His life and labours have added much to our exact knowledge of the characters and sources of medicinal plants and substances; and have elevated the character of British pharmacy at home and abroad.

WATER-SUPPLY.

ON April 2nd, a deputation from the Social Science Association waited upon Mr. Sclater-Booth, President of the Local Government Board, at the offices in Whitehall. Dr. Lyon Playfair, M.P., after a few words on the importance of a better supply of water, not only to towns, but villages, introduced the deputation. Mr. Michael eulogised the Government measure now before Parliament as far as it went, but represented that, to deal properly and thoroughly with the question, an exhaustive inquiry by a Royal Commission was necessary as to the best sources of supply and the best plans for distribution. As regarded the first point, there was no subject on which there was greater real ignorance; and on the latter, it was notorious that the existing water companies were a great hindrance to local authorities, whose efforts were hampered, if not neutralised, by the powers of those companies. Mr. Bailey Denton said that the best evidence that something must be done was the fact that there were no less than thirty water bills now before Parliament. Most of these bills were based on the aggressive principle; that was, they helped themselves from other water-beds than their own, and left the districts so robbed without water at all. He suggested that some provision ought to be made under which landed proprietors might, by storage or other means, supply water to villages, and

recoup themselves for the cost. Dr. Farr and Dr. Guy supported the appointment of a Royal Commission. Dr. Sandwith spoke of the pollution of the water-supply of London; human excrement being, he alleged, found in the cisterns of one of the large clubs in Pall Mall. What was wanted was more wholesome relations between the river and the mouth. He dwelt upon the evil results of intermittent supply. Mr. Sclater-Booth, while admitting that there might be subjects on which inquiry would be useful, pointed out that there had already been a Royal Commission on the water-supply of the metropolis. While, therefore, he should be most happy to represent to the Government the suggestions of the deputation, it would be well if they were supplemented by a statement from the Social Science Association of the points on which a further inquiry might be useful. Dr. Lyon Playfair undertook that this should be done, and the deputation withdrew.

THE GERM-THEORY OF DISEASE.

ON Tuesday evening last, there was a large gathering of the Fellows of the Pathological Society of London, to hear Dr. Charlton Bastian open the discussion on the Germ-Theory of Disease: being a discussion of the relation of Bacteria and Allied Organisms to the Virulent Inflammations and to the Specific Contagious Fevers. Dr. Bastian commenced by referring to the analogy which existed between zymosis and fermentation, in that particles in each case set up processes which resulted in the reproduction of other particles identical with the first. He contrasted Pasteur's views with the transferred emacanis of Liebig, inclining to the views of the latter. The contagium multiplied within the body in a manner which might be compared to organic growth and multiplication. Bacteria were not found in the blood of healthy individuals; yet, in from eight to forty-eight hours after death, they were found in abundance. He contended that bacteria had a causal connection with infection, and that they were not mere "carriers of infection", but were for the most part actual pathological products engendered within the body; that in fact, there was a bacterial degeneration which claimed to rank side by side with fatty degeneration. After expounding his views with much skill and detail, he was followed by Dr. Burdon Sanderson. Dr. Sanderson declined to go into the germ-theory in its entirety, but confined himself to the negative facts that bacteria identical with those found in morbid tissues, might be introduced into the body without any ill effects; and to the positive facts that, in destructive inflammations, bacteria were found only in the outer zone of the disease, where it was spreading, and not in the central parts; and that in relapsing fever spirilla were only found during the febrile paroxysm and not afterwards; and that in erysipelas and sheep-pock, the bacteria were found not in the vesicles, but in the lymphatics of the skin. These facts, he thought, were opposed to Dr. Bastian's views. The time having expired, the Chairman, Mr. Campbell De Morgan, adjourned the discussion until the next meeting of the Society.

A HOME OF HEALTH.

WE have had lately the opportunity of inspecting the Ilkley Wells House Sanatorium, situated at Wharfedale in Yorkshire. There are, we believe, many who will be glad to know that in this fine building they will find what is often a great desideratum, "a home of health", situated in a romantic moorland district, and having all the advantages which have rendered "hydropathic establishments" popular, without any of the relations to quackery which have made many of them objectionable. Ilkley Wells House is a fine pile of buildings, open to the moors, having all the advantages of "Roman wells", pure water, fresh air, a romantic neighbourhood, simple mode of life, and ample arrangements for domestic comfort such as may be found in a great hotel. Built by a company some years ago specially for its present purposes, it has come recently under the management of an orthodox member of the profession, Dr. Leeson of Bradford, who has professional recommendations of a satisfactory kind from eminent members of the profession in London and throughout the northern districts, where he is well known. The chief drawback to many institutions of the

kind—which are all the same largely patronised in spite of them—will here be removed; and Dr. Leeson may, we think, be justified in believing that he has, in undertaking this important enterprise, filled a want which has been much felt, and may expect considerable support from his professional brethren, who frequently desire to recommend overworked and debilitated patients to take a healthful rest, under the most favourable conditions of physical hygiene and mental repose, without knowing where they can safely send them. Ilkley Wells Sanatorium seems to fulfil all the required conditions.

RECENT URBAN MORTALITY.

DURING last week, 5,945 births and 4,275 deaths were registered in London and twenty other large towns of the United Kingdom. The average rate of mortality was 29. It was 22 in Edinburgh, 30 in Glasgow, and 30 in Dublin. Of eighteen large English towns it was lowest (23) in Portsmouth; whilst in Manchester it was 31, Oldham 31, Bradford 32, Nottingham 32, Bristol 33, Birmingham 33, and Wolverhampton 33. The zymotic rate in these eighteen towns ranged from 0.9 and 1.8 in Portsmouth and Leeds respectively, to 5.8 and 6.2 in Wolverhampton and Hull. Scarlet fever is still fatally prevalent in Bradford and Hull, and whooping-cough caused 18 deaths in Birmingham. In London, 2,493 births and 1,873 deaths were registered; the births exceeded the average by 42, and the deaths by 207. The death-rate was 28. To the seven principal zymotic diseases 219 deaths were referred, being 25 below the average, and equal to an annual rate of 3.3. The deaths from scarlet fever were 32, from measles 24, diphtheria 16, and whooping-cough 92. The deaths referred to diseases of the respiratory organs were 534, being 142 above the average. In outer London, the general and zymotic death-rates were 20.0 and 2.1 respectively, against 28.4 and 3.3 in inner London. At Greenwich, the mean temperature of the air during the week was 45.8 deg., or 1.9 above the average. The direction of the wind was variable. No rain fell during the week.

THE BIRMINGHAM MEDICAL INSTITUTE.

THE decision of the Committee of the Birmingham Medical Institute, which we reported in February last, to admit homœopaths to the use of the library, has been the subject of very animated debate. A good deal of unnecessary inkshed has taken place; and one of our contemporaries, which did not at the time see how it could properly refuse paid advertisements of lectures on homœopathy, has yet been highly indignant that homœopaths should be admitted to the use of a medical library. After a very animated discussion in the public newspapers of the town, which we think was much to be regretted, and not always in good taste, and after an extensive appeal by circular to the neighbouring practitioners, it has been once more decided, by a very important majority, that homœopaths may be admitted to the library. The decision does not appear to us to involve any very important principle. It is a question of local liking and personal feeling. If the issue raised had been one of admission to a medical debating society, it would undoubtedly have had a more general application. But there is a wide difference between the membership of a medical society and the mere right given to use a reading-room. We apprehend that none of the half-dozen homœopaths who are now free of the library are a whit nearer to the membership of any of the medical societies of Birmingham. The latter would involve an admission which cannot, we think, be fairly made—the admission that they are capable of fairly weighing medical evidence and discussing profitably questions of medical science and practice. So long as they call themselves homœopaths, and profess the absurdity of basing their whole theory and practice of medicine upon the doctrine that *similia similibus curantur*, we do not see that they can expect to be treated otherwise than spiritualists are treated by reasonable persons, with personal courtesy but professional and polite contempt. Homœopathy, like spiritualism, is not truly a doctrine in any scientific sense, but an abnegation of reason. It is quite certain that it has been largely supported, like spiritualism, by trickery; and that its professors may be broadly divided into dupes of nature and sciolists in art. But just as

physicists and naturalists would not refuse the society of Mr. Crookes or Mr. Wallace on account of their spiritualistic performances, although they would decline to enter into a discussion with them on the subject of their delusions, so the Birmingham medical men, fully persuaded of the honesty of some of the homœopathic practitioners of the town, have decided not to refuse them admission to the medical library, although declining to meet them in consultation on medical subjects, where their delusions render their society uncomfortable, and deprive them of the basis for sound medical reasoning or rational practice. It is a good sign that homœopathic practitioners and homœopathic journals are beginning to plead to be allowed to drop the title of homœopaths, just as they have for some time pleaded that infinitesimal doses are essences and not essentials of their doctrine, and that they are entitled to use the whole armament of rational medicine. When the abandonment of infinitesimal doses is universal, as it promises soon to be, and when the distinguishing and absurd title of homœopathy is extinct, the Hahnemannian folly will be practically at an end. We do not think that time is far distant; and probably the action of the profession in the midland counties may tend, if not exaggerated or misinterpreted, to hasten the consummation.

THE ADULTERATION OF SPIRIT.

DR. ALFRED HILL, the county analyst for Warwick, stated at the Quarter Sessions that the Adulteration Act had worked so satisfactorily in that county, that the number of adulteration cases had decreased from 57 to 10 per cent. The Act was, however, sadly defective, inasmuch as no standard of strength was fixed for distilled spirits. In consequence of this omission, no legal action could be taken in regard to the adulteration of spirits with water. The samples of spirits submitted to him varied from seventeen to forty-four degrees under proof, water being the chief adulterant.

ARMY MEDICAL SCHOOL.

THE summer session of the Army Medical School at Netley was opened on the 1st instant, in the presence of the staffs of the Royal Victoria Hospital and School, and of a few visitors from the neighbourhood. Dr. Fayer, C.S.I., who retired a short time ago from the Professorship of Surgery at the Medical College of Calcutta, and who has lately been appointed Physician to the Council of India and a member of the senate of the Army Medical School, in the place of the late Sir Ranald Martin, also attended. The introductory lecture was delivered by Professor Aitken, F.R.S. The address embraced a variety of topics having a general bearing on the work of military medical officers in the various spheres of the public service, and, though it occupied a full hour in delivery, was listened to with marked attention. In the course of his address, the lecturer paid a warm tribute to the public services, and kind and genial disposition of Sir Ranald Martin, one of the members of the senate of the school, who had passed away since the last session. Sir R. Martin, the lecturer remarked, as much as, if not more than anyone else, had contributed to the formation of the school by his writings, by his determined energy in enlisting the sympathies of others in the cause, and especially by his unflagging exertions as a member of the several sanitary commissions under Sidney Herbert in getting it officially established. He hoped, therefore, that the memorial which his friends and admirers were now seeking to establish, a Ranald Martin prize to be competed for by the candidates of all services at the Army Medical School, would be successfully accomplished, and in a manner worthy of the man whose name it would bear. After Professor Aitken had concluded his remarks, Dr. Fayer, who was introduced by Surgeon-General Fraser, C.B., addressed the assembled candidates, and, after congratulating them on the fields they had severally adopted for their future careers, gave them some excellent advice on the best manner of attaining successful positions in them. He said he could speak to them from personal acquaintance with all three services, for he had been for a time an assistant-surgeon in the Royal Navy as well as in the Royal Artillery; but, as the greatest part of his life had been passed in the Indian Medical

Service, he would more particularly speak of it. Dr. Fayer then gave a rapid sketch of the vast field that was open to medical officers in India, the valuable appointments which were open there to those who distinguished themselves by their professional attainments and character, but particularly on the immense importance of the educational work that was now being carried on among the natives by members of the Indian Medical Service, and would have to continue to be carried on by those who were now sitting on the benches before him. He believed that nothing was establishing a greater influence and hold on the minds of the two hundred millions of natives in India than the diffusion of medical knowledge and practice which was going on through the great medical colleges of Calcutta, Madras, Bombay, and Lahore. When he left the medical college at Calcutta, there were 1,400 natives being trained in medical education there. All the professorial appointments connected with medicine and surgery at these colleges were held by members of the Indian Medical Service who had distinguished themselves by their abilities and professional merit. Dr. Fayer explained at some length the means by which health could be best preserved in India; showed the necessity for early acquirement of the Hindostani language, described how medical practitioners could not only make themselves most useful in the country, but also secure their own personal interests; and, after a long and eloquent address, concluded by a few kind and encouraging remarks to all the candidates for commissions; not only to those who would be shortly passing into the particular field which he had not long since left, but emphatically to all; for, as he said, looking at them from a higher point of view, he could only regard the three medical services as branches of one great united military medical body acting in the general service of the Queen and country. The school has opened with twenty candidates for commissions in the Indian Medical Service, eight for commissions in the British Service, and ten in the Royal Navy. Two surgeons of the Royal Navy have also arrived to go through the course of practical work at the school.

MANCHESTER SICK CHILDREN'S HOSPITAL.

A FANCY fair and bazaar on a large scale was opened in the Free Trade Hall, Manchester, on the 6th instant, for the purpose of raising the sum of £12,000 or £15,000 to complete the Pendleton Sick Children's Hospital. This charity is acknowledged to be one of the most catholic in its objects of any in the district. It is connected with a dispensary in the heart of Manchester, at which about 8,000 patients are now annually treated. Every child under 14 years of age, wherever born, or wherever resident, is qualified on a simple application, without any recommendation, to obtain advice. The inhabitants have entered into the scheme with great spirit and unanimity, and it is expected that a large sum will be realised.

THE WEST RIDING LUNATIC ASYLUM.

THE Easter holidays at the West Riding Asylum, Wakefield, were marked by a series of entertainments of a very high class. Among them was the performance of *Pygmalion and Galatea* by a party of accomplished amateurs organised by Mr. and Mrs. Briggs of Stanley Hall, kindly and influential neighbours of the asylum. The performance was arranged and superintended by Mr. Gilbert, the author of the play, who also acted in it. Mr. Briggs had written a prologue for the occasion, and the programme included a rhyming argument written specially for the occasion by one of the visitors. The mounting and dresses were most complete; and the acting was admirable, Miss Alice Rathbone of Liverpool playing the part of Galatea with singular pathos and a sentiment of exquisite purity which produced a very marked impression on the numerous auditory. Mrs. Briggs, Mr. Dyke, and Mrs. Crichton Browne, sustained the leading parts with great histrionic power. Nearly a thousand of the lunatic inmates were present at the play and at the ball which followed. The West Riding Lunatic Asylum is now well known as one of the most admirably organised institutions of the kind in Europe. Under the directorship of Dr. Crichton Browne, who has the advantage of working under a most liberal and enlightened

Board of Governors, the best results have been attained in every direction. Great scientific activity pervades the institution, as the admirable yearly volumes of reports testify, and as our pages this week and often bear witness. These good results are largely attained by the judicious liberality of the county magistrates, who, having secured the services of an able medical director, reward them fairly, and entrust to him full power of management. In return, they obtain excellent results, a high proportion of cures, an economical expenditure, and withal a model establishment, in which there is no stint, and of which they may be justly proud.

NORTHERN COUNTIES ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

A PRELIMINARY conference of the medical officers of health of the counties of Northumberland, Cumberland, Durham, and Westmorland, was held in the Newcastle Infirmary on Saturday, April 3rd, for the purpose of forming an Association. Dr. Elliot (Carlisle) occupied the chair. The attendance of medical officers was numerous and representative. Letters approving of the object of the conference were read from gentlemen unable to be present. The business, which was strictly of a formal nature, consisted of the passing of resolutions, the election of officers, etc. The annual meeting of the Association is to be held at Carlisle on the first Thursday in July, under the presidency of Dr. Elliot. Quarterly meetings will also be held alternately in one or other of the principal towns of the northern counties.

SEAMEN'S HOSPITAL, GREENWICH.

THE committee of the Seamen's Hospital, Greenwich, appeal urgently for subscriptions. During the past year 3567 patients received treatment; of this number, 2058 were in-patients. This is a larger number than had been relieved in any year since the foundation of the hospital. The committee look with anxiety to the future, for the income of the hospital has materially fallen off, and the cost of necessities has risen, and notwithstanding that, the benefits conferred by it have been greater. The annual expense of the hospital is £9500, whilst the only permanent and reliable source of income, derived from investments, is £3500, which leaves the hospital dependent on voluntary contributions to the extent of £6000. The hospital is thoroughly cosmopolitan. Seamen of every nation are admitted without any letters of recommendation; an applicant, being a seaman, has only to show his need of medical treatment, and he is at once received into the Hospital; and, after recovery, he is retained as a convalescent until he is fully capable of resuming his duties on board ship. The committee therefore appeal with confidence to all classes and all nationalities for the means to carry out their laudable objects. Subscriptions may be paid to the Secretary, Mr. H. C. Burdett, Seaman's Hospital, Greenwich, or to Messrs. Williams, Deacon, and Co.

MERCANTILE MARINE HOSPITAL SERVICE.

A SHORT Bill to provide for the organisation of a Mercantile Marine Hospital Service and the Medical Examination of Merchant Seamen has just been printed. The Bill provides compulsory inspection of seamen, the establishment of hospitals at certain ports to which foreign seamen are eligible under restrictions, the appointment of medical officers and superintendence, and the provisions for creating a marine hospital fund. The Bill is in charge of Captain Pim and Mr. Wheelhouse, and has been drafted under the active influence of Dr. Vavasseur Sandford.

NEWCASTLE AND GATESHEAD PROVIDENT MEDICAL SOCIETY.

A public *soirée* to inaugurate the above society (to the formation of which we alluded some time since) was held last week in the Town Hall, Newcastle. Among those who were present were Mr. C. F. Hamond, M.P., and the Rev. Canon Martin, while letters from Mr. Joseph Cowan, M.P., Mr. Thomas Burt, M.P., and the Mayor of Gateshead, were read, expressing their cordial approval of the movement, and their regret that they were unable to be present at the meeting. The Chair-

man, the Rev. Rowland East, said: "It had struck some that if an institution could be formed on the co-operative system, by which, through a moderate subscription, every member could claim medical advice, without seeking it as a matter of favour, it would be a grand thing for the whole community. This was no new idea. Institutions of the kind had been established in Derby and Liverpool, and were extending in London in every direction. To become a member of the Newcastle and Gateshead Society, a man required to pay 3s. per year only; if his wife became a member, 3s. per year more, and 1s. additional for each child. While they were unable to do without other institutions in the town, none of which would be for a moment underrate, yet it was not a pleasant thing for persons to be indebted to these institutions. It was more in accordance with the independence of man, and the freedom of the human mind, that a person should make an arrangement to pay for medical assistance, just as he paid for his clothing, his bedding, or the education of his children. The Newcastle and Gateshead Society was only four months old: there were already about 1,500 members, but as many more would be required to make it work to the satisfaction of the promoters." Mr. Hamond, M.P., in moving a resolution which pointed out that the death-rate in Newcastle was high, mentioned that £35,000 were spent annually on the sanitary arrangements of the borough, and that an institution which provided for the medical necessities of the working population, while at the same time it encouraged them in habits of forethought, was well worthy of support. We ought never to permit it to be said that Englishmen were less self-reliant in this nineteenth century than they used to be; and it should never be forgotten that self-dependence was the sure road to esteem and respect. As to the Provident Medical Society, its cost would be a mere bagatelle compared with the good results that would follow.

HOAXES.

SOME nameless practical joker has occupied himself in hoaxing the medical men and dentists at Southport by sending a forged letter purporting to proceed from a gentleman in the town who required their attention; the result being, that the majority of practitioners met at the same time on a "fool's errand". A similar hoax was perpetrated not long since; a surgeon having been called out of bed to attend some severe cases of fractures and broken limbs, which turned out to be nothing more serious than the overturning of a waxwork exhibition. It would be as well for the perpetrators of this sort of mischievous folly to remember that they render themselves liable to be indicted for forgery.

SCOTLAND.

THE winter classes have now come to a close, both in the university and Anderson's Institution, Glasgow. The classes in the latter closed on the 25th ultimo, and in the former on the 7th instant.

WE are glad to be able to report that Professor Sanders, whose illness for some months past has given great anxiety to his friends, and has been such a serious loss to the teaching power of the University, is now quite convalescent, and is able to be out for a short time every day.

THE winter session came to an end on Wednesday, March 31st, both at the Edinburgh University and at the Extra-Academical School of Medicine, where prizes were as usual distributed to the successful competitors. The past session has been the most successful one as regards the number of students attending the various classes for many years.

LEITH HOSPITAL.

A LARGE addition to the buildings of the Leith Hospital, which has just been completed, was formally opened on Friday last (April 2nd). The new buildings were begun at the end of 1872, shortly after the receipt of a legacy of £25,000, bequeathed by the late Mr. Williamsen

Ramsay, a native of Leith. The hospital authorities had previously been much cramped in their operations for want of space, and they at once set to work to enlarge their premises. Plans were prepared, and, after careful consideration by the directors and medical officers, were adopted, special attention being paid to the providing of thorough ventilation and sanitary arrangements on the most approved principles. Accommodation is provided for 36 patients, while the old building will in future be entirely devoted to fever cases, with the exception of one room set apart for dispensing. The total outlay in connection with the improvements reaches about £10,000, about £20,000 of capital remaining on hand. At the meeting on Friday, the Provost of Leith, who presided, read a short history of the hospital, which showed that, in the year 1788, a branch of the Humane Society of London was constituted in Leith, and, in 1815, a dispensary was formed; these were combined in 1825. A casualty hospital was established in 1837, and their operations continued until 1847, when all these combined to form the present institution.

ST. ANDREW'S UNIVERSITY.

At a meeting of the St. Andrew's University Court, on Wednesday, March 31st, Dean Stanley, the Rector, presided, and appointed the Earl of Elgin as his Assessor. Among other items of business, the Court appointed Dr. Thomas Keith as an extra medical examiner, and sanctioned an increase of the fee allowed to medical examiners. The Court also appointed Dr. Handyside, lecturer on anatomy at the Royal College of Surgeons, Edinburgh, as substitute examiner in anatomy for this year, in consequence of the illness of Professor Oswald Bell. The Court disposed of several applications for recognition of lectures as qualifying for medical graduation.

GLASGOW INSTITUTE FOR INCURABLES.

DURING the past week, a bazaar, on a very extensive scale, has been held in the Battle Palace, Glasgow, with the object of raising funds for the erection of an institution and cottage-homes for the relief of incurables in Glasgow and the West of Scotland. The proceeds of this bazaar, which was one of the most important and successful ever held in Scotland, reached the very handsome sum of nearly £12,000.

FEVER-PATIENTS IN EDINBURGH.

At the last meeting of the Edinburgh Town Council, a letter was read from the Clerk of the Royal Infirmary, in which it was stated, in answer to a previous communication from the Council regarding the future accommodation of fever-patients, that the idea of having a fever-hospital or fever-wards of any kind in connection with the new Infirmary, had been abandoned; but that the managers had determined to retain the piece of ground at the east end of the present infirmary site, which contains the present fever-wards and the old fever-hospital, for the accommodation of fever-patients, both in ordinary times, and during any epidemic. They are prepared to make provision for the treatment of seventy-four fever-patients, and will afford the Town Council every facility for the treatment of any infectious diseases in excess of this number, either in these buildings or in others, temporary or permanent, which may be erected on the same site. An unanimous vote of thanks to the managers of the Infirmary was voted by the Town Council.

WATER-SUPPLY OF EDINBURGH.

THE trustees for carrying out the Moorfoot scheme for the better supply of water to Edinburgh, have been compelled to abandon the site originally fixed on for one of their largest reservoirs, in consequence of the discovery of a chasm in the rock bottom. A special meeting of the trust was held last week to find a new locality; and they virtually decided on a site about a mile lower down the Fullarton Burn, which is the feeding stream. A series of borings have been made at this spot, and show that solid rock is to be found all along the proposed line of embankment within a few feet of the surface. It will probably be necessary, to avoid future difficulties, to obtain a fresh Act of Par-

liament sanctioning the proposed change of site. As, however, it has been found that a reservoir of considerably less size than was anticipated will be required, it is calculated that, when all the expenses incident to a supplementary Act have been paid, the public will save over £20,000 of the expenditure originally estimated for this part of the scheme. The present delivery of water is reported at 927.96 cubic feet per minute, equal to 30.89 gallons per head daily to a population of 270,300.

LECTURES ON SURGERY AT THE GLASGOW ROYAL INFIRMARY.

WE learn with some satisfaction that the ice has been, in a manner, broken in a direction which we have more than once advocated in these columns. Dr. H. C. Cameron has obtained the consent of the directors of the Royal Infirmary to conduct a course of lectures on systematic surgery in their lecture-room. Of course this is simply the permission to use a lecture hall in the Infirmary; but we may be allowed to look on it as what Scotch theologians are accustomed to call the thin end of the wedge. If, as we anticipate, the advantages which a lecturer will possess from a connection with such an institution become apparent, then it will speedily stir up others to follow his example. We trust that from this small beginning a Royal Infirmary School of Medicine will develop. The teachers in such a school can hardly fail to be recognised by the University.

DONATION FROM THE GLASGOW FACULTY TO THE WESTERN INFIRMARY.

It is with unfeigned pleasure that we record the very handsome donation of five hundred guineas, voted by the Faculty of Physicians and Surgeons in Glasgow towards the funds of the Western Infirmary. This example of liberality on the part of the profession in Glasgow cannot fail to raise them in the estimation of the community.

IRELAND.

ON last Monday, a motion for petitioning Parliament to prohibit the sale of intoxicating liquors on Sundays in Ireland was carried by the Corporation of Dublin.

ON the 3rd instant, Mr. Rainsford, Assistant-Surgeon to St. Mark's Ophthalmic Hospital, Dublin, was appointed to the new chair of Ophthalmic Surgery in the Ledwich School of Medicine.

DR. BELL has been appointed Lecturer on Chemistry to Dr. Steevens's Hospital, in the room of Dr. Cameron, recently appointed Professor at the Royal College of Surgeons. Mr. F. W. Warren has succeeded Dr. Bell as Lecturer on Botany.

AT the last meeting for the session of the Surgical Society of Ireland, held on April 2nd, the President, Mr. Jolliffe Tufnell, handed over to the College of Surgeons a bequest from the late Mr. L'Estrange, in the form of a number of surgical instruments invented by him, which he wished the College to retain.

BEGGAR'S BUSH BARRACKS.

NOTWITHSTANDING the reassuring character of Mr. Hardy's statement in the House of Commons, we have reason to believe, from inquiries which we have made, that the sanitary condition of these barracks is far from being satisfactory. The general health of the officers is poor, and they suffer a great deal from dysentery and diarrhoea. The attack of fever from which Captain Van der Weyer suffered is very generally believed to have been contracted in the barracks. Complaints are made also of the apathetic manner in which the reports of the medical officers are received and ignored by the authorities. It seems to be the rule to discard the advice of the medical officers in the military department, until it has been proved by the occurrence of the predicted evils. This was the case at Woolwich; and we know of several similar instances in the Dublin district. When a complaint is made by a sanitary officer, the

rule seems to be to detail a board who rely upon their noses, as their most instructed organ, to smell the cause of evil, and if the stench do not at the time seem very bad, these gentlemen report on the side of economy and delay. Usually the men suffer more than the officers, but on this occasion the officers have been and are sufferers, and the remedy will possibly be applied.

THE MEATH HOSPITAL.

DR. STOKES has resigned his office of Physician to the Meath Hospital. We regret that Dr. Stokes's retirement is in consequence of his failing health. We are glad, however, to state that he will still continue an active member of the profession; and, when lightened of his arduous duties as a clinical teacher, we trust that he may be enabled long to ornament the profession of medicine in Ireland, of which he is the acknowledged head. Dr. John W. Moore, Assistant physician to the Cork Street Fever Hospital, has, we are glad to hear, been appointed Physician to the Meath Hospital in succession to Dr. Stokes.

IMPORTANT INQUEST IN DUBLIN: CHARGE OF NEGLIGENCE AGAINST THE APOTHECARIES' HALL OF IRELAND.

AN important inquest has been held at Sandymount, one of the eastern suburbs of Dublin, upon the body of a Mr. Marsden, who recently died from the result of an explosion, which took place while the deceased was engaged in the manufacture of oxygen gas. Mr. Marsden, who was employed in the Bankruptcy Court, had been in the habit of giving amateur exhibitions of dissolving views and such like amusements, in which the oxyhydrogen lamp was used as an illuminator. He had always prepared the gas and arranged the apparatus, without any accident having previously occurred. The deceased purchased the materials, chlorate of potash and what purported to be oxide of manganese, from the Apothecaries' Hall of Ireland. He mixed the materials in the usual way, but, on applying heat, the mixture exploded, injuring the operator so much that he died in two days. The evidence before the court was to the effect that the substance sold by the Apothecaries' Hall as oxide of manganese was black antimony, which, on being mixed with the chlorate of potash and heated, gave rise to the fatal result. The jury, after a very brief deliberation, found the following verdict: "That the deceased, James Marsden, aged 40, came by his death on the 20th of March in consequence of injuries accidentally received on the 18th of March from manufacturing oxygen gas, and that the explosion was caused by sulphuret of antimony having been supplied from the Apothecaries' Hall in mistake for manganese." We need scarcely say this verdict is tantamount to a grave charge of negligence against the Hall. The "Hall" is largely engaged in compounding prescriptions, and is the responsible authority in Ireland for the supervision of pharmaceutical chemists.

PURIFICATION OF THE LIFFEY.

AT a meeting of the Corporation of Dublin, held this week, it was resolved that the Port and Docks Board be invited to join them in taking the opinion of counsel on the question of the liability of the Corporation or Port and Docks Board as to the cleansing of the Liffey from Carlisle Bridge to Banack Bridge, both bodies to abide by the decision. An extensively signed memorial lies for signature by the ratepayers, praying that the Government will not accede to the request of the Corporation in the matter of borrowing £500,000, without full inquiry into the whole subject by a Royal Commission.

NORTH DUBLIN UNION: COST OF MEDICINES.

DR. KING, one of the inspectors of the Local Government board, attended at the board-room of this Union on the 1st inst., for the purpose of examining books and documents relating to the cost of medicines, etc., obtained by the workhouse dispensaries during the year ending 29th September, 1874. This matter has already been referred to in our columns, and we merely state now that the investigation is owing to the considerable difference that existed in last year's medical contracts in this Union as regards the South Dublin Union.

SPECIAL CORRESPONDENCE.

BIRMINGHAM.

[FROM OUR OWN CORRESPONDENT.]

The Medical Institute: Annual Meeting: Admission of Homœopaths.

THE principal subject of professional interest lately has been the progress of our Medical Institute. The policy of the Election Committee having made a legal qualification the basis of membership, and thus admitted some half-dozen homœopathic or other "unorthodox" practitioners amongst the two hundred members, much exception was taken both to the admission and the mode of it. Some hard words were used; and at a meeting for the election of a "Bye-Laws Sub-Committee", a good deal of personal and party feeling was shown. However, at a large meeting—the first annual one—held last week, the policy and the principles of the original, and of the election committee, were amply vindicated and approved. Both sides of the question have been temperately stated in your issue of February 20th, but it will be worth while to record more fully than usual this last meeting, which was of much interest and importance. In the report which was presented, the committee repudiated the justice of allegations which had been made against their fairness and honesty, and invited a fair and full discussion.

In moving the adoption of the report, Mr. Alfred Baker, with considerable humour and satirical power, criticised Mr. Pemberton's course of action, and demonstrated that the action of the committee was perfectly open, legitimate, and honourable.

Mr. Pemberton then stated his views much as he had already done in the pages of a contemporary, but with this important addition, that "if there was the shade of a shadow of a thought that he attributed a want of honour or honesty to the gentlemen named, he entirely and completely withdrew it." This disclaimer was received with much applause. He hinted that he and others might withdraw if some fresh arrangements were not made for the future conduct of the "possibly great institution"; but finally seemed to waive the main question at issue, and proposed the following resolution: "That this meeting regrets that the original committee did not call a special meeting of the profession before they accepted donations from professed homœopaths, thereby permitting a committee only to decide so grave a question."

Dr. Heslop, in an eloquent speech, said that in his younger days he, too, had earnestly denounced his homœopathic brethren. He was then what he was made by the prejudices of his teachers; but now he stood before the meeting made by his experience, by his observation, and by his liberal reflection upon those who differed from him in any form. He was not responsible for the thoughts that he had when fresh from the benches of prejudice, and from lecturers who hounded down those who differed from them in opinion; but that day, with grey hairs on his head, having pondered over matters in every sphere of thought, he was going to challenge their opinion, not upon the side issue which Mr. Pemberton had put before them, but upon the entire issue between the committee and that gentleman. After some criticisms upon his course of action, it was explained emphatically that the proposed institute would not be an ethical society, nor one for regular meetings for debate; for some time it would be but a set of rooms, in which there would be books. Some of the rooms would be rented, possibly, in twenty years by certain medical societies, acting under their own regulations. Would they say that no one, who did not quite agree with them in the whole range of speculative therapeutics, should be allowed to come into those rooms because they did not like his opinions? Did the College of Surgeons close its laboratory, museums, and lectures to homœopathic surgeons? Let them not, however, be led by anything; and he besought them to be true, not to the worst, but to the best traditions of their honourable profession. The speech, as delivered, was calculated—as we heard it remarked—to make one feel proud of the profession, and it carried with it the large body of the meeting. The mild resolution of censure as to the manner of election was rejected by a majority of thirty; and the approval of the report, and virtually of the liberal course of action, was then carried amid much enthusiasm, and without a single dissident.

REQUESTS.—Mr. W. James, an old inhabitant of Birmingham, who formerly took a very active part in the public affairs of the town, has left £100 to each of the following institutions, free of legacy duty: The General Hospital, the Queen's Hospital, the General Dispensary, the Deaf and Dumb Institution, the Blind Asylum, and also to the Orthopaedic Hospital.

ASSOCIATION INTELLIGENCE.

COMMITTEE OF COUNCIL: NOTICE OF MEETING.

A MEETING of the Committee of Council will be held at the office of the Association, 36, Great Queen Street, Lincoln's Inn Fields, London, on Thursday, the 15th day of April next, at two o'clock in the afternoon.

FRANCIS FOWKE, *General Secretary*.

36, Great Queen Street, London, W.C., March 18th, 1875.

METROPOLITAN COUNTIES BRANCH.

A GENERAL Meeting of this Branch will be held at the house of the Medical Society of London, 11, Chandos Street, Cavendish Square, on Friday, April 16th, at 8 P.M.; when a discussion will be opened by Mr. HOLTHOUSE on the subject of Legislation for Habitual Drunkards.

ALEXANDER HENRY, M.D. } *Hon.*
ROBERT FARQUHARSON, M.D. } *Secs.*

SOUTH HANTS DISTRICT: SOUTHERN BRANCH.

THE next ordinary meeting will be held at the Red Lion Hotel, Fareham, on Tuesday, April 20th, at 4.45 P.M.

Notice has been received of the following communications:

1. Dr. MANLEY: The Diagnosis of Insanity.

2. Mr. G. H. CASE: A Case of Polypus of the Rectum.

Dinner will be provided at 6.15 P.M., charge 6s., exclusive of wine. Members intended to be present, are requested to communicate with Dr. Case, Fareham, on or before April 17th.

J. WARD COUSINS, *Hon. Sec.*

NORTH OF ENGLAND BRANCH.

THE Spring Meeting of the above Branch will be held at the Assembly Rooms, Bath Terrace, Tynemouth, on Thursday, April 29th, at two P.M. The following papers have been promised:

1. On the Treatment of Habitual Drunkards. By Dr. Eastwood.

2. On the Pathology of Catarrhal Pneumonia. By Dr. Macdonald.

3. A case of Extrauterine Foetation. By Dr. Byrom Bramwell.

4. A case of Extrauterine Foetation. By James Wilson, Esq.

5. A case of supposed Renal Calculus. By Anthony Bell, Esq.

Gentlemen who are desirous of reading papers, exhibiting pathological specimens, or making other communications, are requested to communicate with the secretary, at their earliest convenience. Dinner at the Bath Hotel, Tynemouth, at four P.M. Tickets, 7s. 6d., exclusive of wine.

G. H. PHILIPSON, M.D., *Honorary Secretary*.

Newcastle-upon-Tyne, April 3rd, 1875.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH: ORDINARY MEETING.

THE sixth ordinary general meeting of the session was held on March 11th, at the Midland Institute, Birmingham: present, W. C. GARMAN, Esq., President, in the Chair, and 33 members and visitors.

New Members.—Mr. J. G. Brown, Birmingham, and Mr. A. W. Orwin, Dudley, were elected members of the Branch.

Communications.—The following communications were made.

1. Dr. MACKAY showed cases of Bronchiectasis after Epyema; 2. Alopecia Areata; and 3. Chronic General Eczema.

2. Mr. LAWSON TAIT showed a Pathological Specimen.

3. *General and Special Hospitals*.—Dr. MACKAY read a paper on General versus Special Hospitals, with reference particularly to the treatment of skin-diseases. After stating arguments in favour of general against special hospitals, it was concluded that the latter were now fully recognised by the profession; (1) when they were markedly more advantageous to large classes of cases—e.g., hospitals for disease of women and of children, and for chest-diseases; (2) when adapted for cases usually declined in general hospitals—e.g., epilepsy and paralysis. A third reason commonly advanced for their recognition was, that they advanced professional knowledge; but this alone could not be held as a sufficient reason, for the same end could be better obtained by special departments in general hospitals, if properly and liberally organised. Illustrations were drawn from the practice of certain special skin-hospitals in London as compared with special departments for the same diseases in the large metropolitan hospitals; and the formation of such departments at all hospital schools was advocated as most desirable in the interests of the profession as well as of the public.

4. Mr. F. MANBY read a paper on Rheumatic Hyperpyrexia.

5. Dr. WARNER related a case of Rheumatic Hyperpyrexia treated by the Cold Pack. A discussion followed, in which the President, Dr. Totherick, Mr. Lawson Tait, Dr. Hinds, Dr. Sawyer, and Dr. Foster took part.

The late Mr. F. Turton.—It was moved by Dr. FOSTER, seconded by the President, and resolved unanimously:

"That this Branch desires to express its deep regret at the early death of one of its members, Mr. F. Turton of Wolverhampton, who for many years was an active and highly esteemed member of the Branch, and on several occasions a valued member of the Council."

BATH AND BRISTOL BRANCH: ORDINARY MEETING.

THE fifth ordinary meeting of this Branch was held at the Royal Hotel, College Green, Bristol, on Thursday, April 1st, at half-past seven o'clock; F. MASON, Esq., President, in the Chair. There were also present forty members.

New Members.—Mr. S. Craddock of Shepton Mallett was elected a member of the Association and of this Branch; Mr. J. B. Colthurst was also elected a member of this Branch.

Croup and Diphtheria.—Dr. E. L. Fox read a paper on Croup and Diphtheria; and an animated discussion followed, in which Dr. Caddy, Mr. Weatherly, Dr. Goodridge, and Messrs. Bartrum, C. H. Collins, Craddock, Steele, and Dr. Swayne took part.

Psoas Abscess.—Mr. STEELE read a paper on the Causes of Psoas Abscess. It was followed by some remarks by Mr. C. H. Collins.

Dr. Rumsey.—The President introduced the subject, and the Secretary read the resolutions passed at the meeting at Somerset House. Dr. DAVEY proposed, and Mr. BARTRUM seconded:

"That every assistance should be afforded, and the deep sympathy of this Branch be expressed for Dr. Rumsey."

Dr. PAYNE of Stroud confirmed the good feeling of the profession in Gloucestershire to Dr. Rumsey, and the anxiety to assist him and do him deserved honour.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 7TH, 1875.

CAMPBELL DE MORGAN, F.R.C.S., F.R.S., Vice-President, in the Chair.

THE GERM-THEORY OF DISEASE.

Dr. CHARLTON BASTIAN read a paper on this subject, which is published at p. 469.

Dr. BURDON SANDERSON said it had been suggested to him to open the discussion; and he rose to do so, though the hour warned him that he must be brief. The subject before the Society was one of the greatest interest and moment. Ere commencing, he should like to limit the subject; if he were bound to discuss the germ-theory, he should decline to enter upon it. Four years ago, he had put together the strongest grounds for it which then existed. In those processes of disease in which organisms were found, there were two forms of life: viz., the life of the tissues, and a life introduced into their life. The latter life was derived from the affected organism. It was not possible for protoplasm, to say nothing of bits of protoplasm, to be removed alive from the organism. It was impossible to accept this hypothesis. He felt that this was an important fact. He was now aware of what he was not previously aware of: viz., that these views had been brought forward by Hensle in 1840. There the germ-theory was put forward in a most complete form. If the Society had at that time begun discussing the subject, it might have been discussing it still without having advanced at all. If it had done so, like the French Academy, it would have fallen behind the times. This Society was founded for the observation and registering of facts. It had now left, or was leaving, this for the investigation of morbid processes, as in the discussions on tubercle and cancer. But there was no reason, after changing its ground, to change its method. As to the germ-theory, if any pathologist who had investigated it were asked if he believed in it, he would answer, "I cannot give you any opinion. There are numerous observations made, upon which an opinion can be formed." But, if he were asked as to his personal opinion, he would probably shrug his shoulders. What he wished to ask after this was: "Is there anything else which can be discussed?" There was something which might be usefully discussed. Time was too brief for the discussion and enunciation of what

were pathological and not biological questions. Firstly, there was a series of negative facts. There were bacteria, which, on microscopical examination, were identical with those of morbid tissues, and could be introduced into an organism without results. But this did not contradict the fact that some bacteria, when so introduced, did produce marked results. It was known that there was no substance which could produce fever in its different stages, except albuminous substances in a state of decomposition. Already it was known that it could not be said that the bacteria found in these substances produced these results; for an alcoholic extract could be made, which would also be able to produce fever. Then there was a series of positive facts. In all destructive inflammations, bacteria were present in the fluids of the part affected. In all such inflammations, these organisms were present. Different names had been given to them by different observers; but all had found them under the same circumstances. Then, there was the other fact that all destructive inflammations spread. This, together with the bodies found, furnished characteristics special to these inflammatory processes. Since his first communication to the Society was made, they had been found in diphtheria, in puerperal fever, and in the process of erysipelas. In spreading erysipelas, bacteria were found in the lymphatic spaces of the skin, but only in the early stages of the disease. They belonged to the spreading zone, but were not found in the interior of the part affected. There was an intimate relation betwixt the bacteria and the process, but not as a result. Then, there were other facts mentioned by Dr. Bastian. As regarded specific disease, the position was a most difficult one. In two diseases, however, viz., in relapsing fever and in sheep-pox, there were distinct forms. In relapsing fever, spirilla had been observed first by Obermeier in Berlin. The spirilla existed only during the febrile paroxysm, and disappeared afterwards. The question was a very difficult one. Were they spontaneously annihilated by the febrile process? They were specific and distinct in their form. If the evidence rested wholly upon Obermeier, it might be alleged that he was an enthusiast; but his observations may be confirmed by many other observers. In an epidemic at Breslau, the observations of Obermeier were corroborated by Dr. Litten; indeed, they had been confirmed by all who had had an opportunity of making observations. It was impossible, then, to accept Dr. Bastian's explanation. In sheep-pox, there were two processes. There was the development of pustules in the skin, quite clearly seen in various stages of progress, forming a complete series. Then there was a complete series of development of organisms, commencing in the corium and extending into the rete Malpighii, not in the skin, but in the lymphatics. These changes were synchronous with changes in the fluid in the vesicles. It was impossible to deny the fact, that some relation must exist betwixt them. It was not worth while to maintain that the organism was the cause of the process, nor that the process was the cause of the organism. The environment of an organism being always affected it, but the organism did not affect its environment. The two processes were associated; but we had yet to find out which was cause and which effect. What we had to find out was, what organic forms had an inseparable connection with the morbid processes. It was irrational to pass by facts which had been noted by good observers, and about which there was no reasonable doubt. If they were true, they must be taken into consideration; if they were false, they must be rejected.—On the motion of the CHAIRMAN, the discussion of the subject was adjourned to the next meeting.

MEDICO-CHIRURGICAL SOCIETY OF EDINBURGH.

WEDNESDAY, MARCH 3RD, 1875.

RUTHERFORD HALDANE, M.D., President, in the Chair.

Exhibition of Patients and Specimens.—Mr. JOSEPH BELL showed a patient, who, some months ago, while sharpening a scythe, had sustained a frightful Wound of the Neck, by the scythe falling along with the heavy vice in which it was fixed. The wound extended diagonally across the neck, cutting the edges of both sterno-mastoid muscles, and dividing the larynx into three fragments. After performing tracheotomy, with the assistance of Dr. Lucas and Mr. Thomson, Mr. Bell carefully replaced and stitched together with numerous catgut sutures the broken fragments of the larynx. A rapid recovery ensued, and the tube was taken out on the eighth day.

Dr. P. H. WATSON showed a specimen of Giant-cell Sarcoma of the Tibia. The disease had begun in the periosteum. Amputation was necessary.

Dr. WATSON showed an Elbow-joint excised by the true Subperiosteal Method of M. Ollier of Lyons; also various joints and bones from the carpus and tarsus, excised by him. In all these operations, he stuffs the wound with lint soaked in a solution of chloral; then

applies a firm compress of the same over the wound, before removing Esmarch's bandage, so that the operations are absolutely bloodless. The first dressing is not removed for forty-eight hours.

Dr. WATSON also showed an Upper Jaw removed for Epitheliomatous Tumour, which had spread from the gum through an aperture in the alveolar margin.

Dr. THOMAS KEITH showed two large Fibrous Tumours of the Uterus, and a photograph of a third, which he had lately removed along with the uterus and both ovaries in each case. All the patients had recovered. He believed these were the first successful cases of this nature in Scotland.

Dr. ARGYLE ROBERTSON showed an Eyeball with a large Tumour attached to its posterior surface, which he had lately removed from the orbit of an elderly female. The whole contents of the orbit were removed, and it was sponged out with chloride of zinc. The disease returned after some months.

Dr. A. ROBERTSON also showed an Eyeball atrophied, in which a piece of stone had been embedded for fifteen years.

Mr. JOSEPH BELL showed a specimen of Exfoliation of the whole Mucous Membrane of the Female Bladder, which he had removed *per urethram* in a sloughy state, about a fortnight after delivery, from a patient of Dr. Thatcher. She was making a good recovery, and already could retain urine for about two hours.

Dr. JAMES DUNSMURE, jun., showed a specimen of Spinal Cord from a child who had died of Cerebro-spinal Meningitis, in which recent lymph one-eighth of an inch in thickness was found.

Dr. A. G. MILLER showed a Bulbous-pointed Catheter, which he lately had made an inch longer than the common ones.

Dr. MILLER showed also a specimen of Epithelioma from the Lip of an old woman who was not a smoker.

Grouse-Disease.—Mr. ANDREW WILSON, Lecturer on Comparative Anatomy and Zoology, Edinburgh, read a paper on the Grouse-Disease, in which he described certain appearances resembling those of an acute inflammatory lesion, which he had observed in grouse perishing from the so-called "disease". Mr. Wilson strongly supported the hypothesis of an epidemic disease, as opposed to that of parasitism or helminthiasis. He contended that, whilst the latter theory might be applicable to a certain number of cases in which an excess of parasites caused death, the theory could not explain the nature of, or account for, a fatal issue in by far the greater majority of cases, in which a moderate and usual degree of parasitism was present, but which cases presented no appearance of fatal helminthiasis. Mr. Wilson drew an analogy between the pleuropneumonia of the veterinarian and the presumed symptomatology of the grouse-disease. The latter lesion, he felt persuaded, would ultimately be found to affect the respiratory tract. The paper concluded by expressing the hope that proprietors of lands and sportsmen would afford means and opportunity for the investigation of the grouse-disease, in the interests of the preservation of moors and game.—The PRESIDENT thanked Mr. Wilson for his interesting paper.

Cases in Conservative Surgery.—Dr. MACDOUGALL of Galashiels read a paper entitled, "Notes of some Cases of Conservative Surgery". In it he related:—1. A case of excision of the whole tibia during the progress of acute necrosis; the patient was shown with an excellent limb and full movement of both knee and ankle-joints, with very little deformity; 2. A case of primary subperiosteal excision of the elbow-joint, and some inches of the humerus; the patient was also shown; he had a most useful arm, with very free movement of the joint; 3. A case of excision of elbow-joint, with part of the humerus, to remedy contraction following a burn, and permit of healing. This patient was not shown, but a photograph was exhibited, showing that a most useful limb had been preserved.—Mr. SPENCE expressed his interest in the paper. He did not approve of amputation in acute necrosis, as his experience had shown him that a patient had a better chance of life with his leg on than with it off in this disease. By excising the bone, however, even before its separation was complete, an useful limb was preserved, and risk to life was diminished and suffering abridged. He thought the bloodless method was exceedingly suitable in such cases. He believed that so-called subperiosteal excisions of joints were impossible in most cases of gelatinous disease, as the periosteum was really destroyed by the disease. He had no fear of the occurrence of flail-like joints, as much more frequently too little bone was removed than too much.—Dr. P. H. WATSON expressed his sense of the value of the paper, and the good results of the cases.—Mr. CHENE differed from Dr. Macdougall's nomenclature of the case of acute necrosis. He did not think the bone was dead, but only suffering from a tendency to death; and he believed that, by opening abscesses in such cases with antiseptic precautions, the necrosis could be prevented.—Mr. SPENCE said that acute necrosis was an useful conventional term, and that in many cases the whole bone was not actually dead, but portions

remained adherent to the periosteum, from which eventually new bone formed.—Dr. P. H. WATSON showed the wide application of the term acute necrosis, including as it does both the process of dying and the process of repair. With reference to the mysterious effects of certain methods of treatment referred to by Mr. Chiene, the whole question lay in a nut-shell. If a piece of bone were dead, it would remain dead despite any treatment; if not dead, it could be kept alive without any special treatment.—Mr. JOSEPH BELL, in praising the paper, and especially the case of excision of the tibia, briefly described two cases in which, in impending necrosis, he had recently excised the whole shaft of the ulna with good result, and complete reparation of the bone.—Dr. MACDOUGALL stated, in answer to Mr. Chiene, that, in the case of necrosis, the bone was separated almost entirely from the first; but that, in many other cases of acute periostitis, he had cut down on the abscesses with excellent results, without any anti-septic precautions.

GLASGOW PATHOLOGICAL AND CLINICAL SOCIETY.

MARCH 9TH, 1875.

W. T. GAIRDNER, M.D., President, in the Chair.

Morbid Specimens and Patients.—Dr. H. C. CAMERON showed an Epulis just removed; also a Cystic Tumour of the Mammary; this was referred to committee.—Dr. WOOD SMITH presented an elderly man with a large polypus in posterior nares. Dr. GEORGE BUCHANAN presented a specimen of cancer of the knee.

Intraocular Tumour.—Dr. THOMAS REID showed a man about 50 years of age, with a tumour in the ciliary region. The tumour occupied the lower third of the anterior chamber; it had a nodulated appearance, and extended backwards to the equator of the eye; there was separation of the retina. The duration of the disease seemed to be about twelve months. As enucleation would likely be required, the specimen might come up before the society hereafter.

Defect of Corpus Callosum.—Dr. D. N. KNOX brought up a report on the case of defective corpus callosum presented by Dr. Alexander Robertson to the Society in January. The patient was a woman about 40 years of age, affected with idiocy of a low type; she could walk, but seldom did so; she usually lay on her back; she never showed any recognition of her attendant, although she could evidently see and hear. Her head was of average size, but the occiput flat, and the brow low. There was no paralysis, but slight club-foot. The brain weighed thirty-six and a half ounces (after being in spirits for ten days). The hemispheres were nearly symmetrical, but these fell outwards, and at once showed the parts in the floor of the lateral ventricles (the membranes, however, had been removed from one hemisphere). The corpus callosum was wholly wanting, or only represented by a very slight ridge scarcely perceptible in front, but one-tenth of an inch behind. About half way back, it separated from the fornix, and at last ran into the lower part of the hippocampal convolution. The fornix was completely divided in the middle line. A trace of the septum lucidum was found at the side, but the fifth ventricle was quite open and communicated with the general ventricular cavity. Various defects were found and described in the convolutions. It could not be said whether the soft commissure had existed. Dr. Knox gave a review of the literature of the subject, from which he concluded, that in those cases in which the commissure system is wholly wanting, or very rudimentary, idiocy or imbecility prevails; and that in those cases in which the corpus callosum is only partially defective, while the other commissures are present, intelligence but slightly below the average, with dulness and childlikeness, are the usual mental characteristics.

Melanotic Cancer in Liver, Peritoneum, and elsewhere. Peculiar reaction of Urine with Nitric Acid. Fatty Tumour in Uterus. Unusual Murmur referred to Pulmonary Artery.—Dr. GAIRDNER presented a number of specimens illustrative of melanotic cancer from the body of a female patient, aged 40, who died in the Western Infirmary. The parts chiefly affected were the liver, omenta, mesentery and peritoneum, and, in a minor degree, the pleura, lungs, and kidneys. The heart was normal as to size, but had been during life the seat of a peculiar murmur; but the whole of the cardiac points in this case were referred to a committee for investigation. The whole clinical history that could with any probability be associated with the enormous masses of disease presented, did not extend back much more than four weeks before death. The patient, an intelligent and respectable married woman, affirmed most positively that, with the exception of several rheumatic attacks during the last four years (the last being three months before admission), she had always enjoyed good health; the catamenia had, however, ceased since her first severe attack of rheumatism, which had confined her to bed for five months, and had left her very weak. After this, she had suffered from palpitations, but had no drowsy, and had been attending to her household duties up to a fortnight before

admission. At that time she caught a severe cold, and immediately afterwards her abdomen began to swell so rapidly that in two days she was as large as she ever became afterwards, and also suffered seriously from cough and difficulty of breathing. These symptoms were accompanied by a great falling off in the quantity of her urine, which became very high coloured. The bowels had been very costive throughout. The family history was without significance. The patient was under observation only from February 3rd to 18th, 1875, making the whole duration of the fatal illness, as far as could be ascertained, about a fortnight before, and a like period after her admission to the infirmary. The axillary temperatures (during the period of observation taken twice daily) were very little elevated, the absolute maximum being 100.2 deg.; the mean of fourteen morning temperatures 98.8 deg.; of thirteen evening temperatures 99.3. The quantity of urine averaged twelve ounces daily, varying from six to sixteen ounces. It was high coloured and of high specific gravity (1035), sometimes clear, sometimes with a deposit of urates. By all the tests successively and carefully employed on several occasions, it proved to be non-albuminous, but a peculiar reaction with nitric acid attracted attention from the first, and was throughout observed, viz., a darkening of tint, almost amounting to a sooty discoloration, though nothing could be collected as a distinct sediment. A similar darkening of the urine took place spontaneously after keeping it for some time, without loss of acidity or distinct decomposition. Dr. Finlayson made special observations on this peculiar reaction, and a portion of the urine was committed to Professor Ferguson, but without any very definite result in the way of chemical analysis. Almost the whole of the positive symptoms connected with the disease on admission were those of abdominal distension, which was obviously in part from fluid in the peritoneum, but in part also from a much enlarged liver, which could be easily felt. There was, in a minor degree, oedema of the legs, but this was ascertained to be of later origin than the abdominal swelling, and the lungs gave signs of oedematous congestion. Five days before death, severe pain occurred in the abdomen, which was not allayed by external soothing applications, and was accompanied by considerable perspiration and a rapid pulse (112), but not by any appreciable increase or diminution of surface temperature. This severe pain recurred at intervals, and at last became constant, being only relieved by hypodermic injections of morphia for a short time, and ultimately producing exhaustion with a fatal result on February 18th. The *post mortem* examination showed a great accumulation of dark brownish fluid in the peritoneum, but scarcely any adhesions, and no recent lymph. This fluid was highly albuminous and did not react like the urine, as above described, with nitric acid, nor could it be definitely stated to differ from ordinary peritoneal serous effusion, though somewhat darker in colour. The liver was much enlarged, extending nearly to the umbilicus and right iliac margin; its weight was estimated at not less than eight pounds. The masses of cancerous matter in its substance were mostly of a bistre or soot-black colour, more or less deep; but a few of them were quite free from this peculiar pigment, and resembled ordinary cancerous tubercles both in form and colour. It appeared, however, to Dr. Gairdner at the time, that the non-pigmented deposits were not only smaller, but, judging from their consistence and obvious structural characters, probably of an older formation than the pigmented, which were larger, softer, and apparently less circumscribed than the others. The largest of the nodules was about two inches in diameter and slightly umbilicated. Dr. Coats also found a considerable amount of infiltrated pigment, apparently replacing the normal hepatic tissue, without any distinct nodular arrangement. The greater and lesser omenta and the mesentery were everywhere closely occupied with growths, which, by crowding together, constituted a thick mass of morbid material, in which the natural structures were almost lost. In the greater omentum, these growths individually varied from a very small size up to that of a filbert, most of them, however, being about the size of peas, and having very much the appearance and colour of preserved black currants. Most of them were of soft consistence, and some of them after a little keeping were almost diffident on section. The rest of the peritoneum, and, to a less extent, the pleura, were occupied by similar growths, mostly, however, flat and sessile, up to a diameter of a quarter of an inch, and varying from a brown to a pale tint. In the substance of the lungs, a few similar growths were found, but of small size. In the kidneys (which in other respects were normal), a few very minute black deposits were found, not larger than pin-heads. Dr. Joseph Coats examined many of these growths microscopically, and made a detailed report of which the following is an abstract. The nodules on the mesentery of the small intestine showed an enormous number of cells, having various shapes, mostly rounded, but many tailed, and a few spindle-shaped. The cells were by no means all pigmented, even where the colour of the growths, as observed by the naked eye, was deep brown or almost

black. On the contrary, the pigmented cells were in a minority, usually in a proportion of one pigmented cell to four, or from this to ten, unpigmented. The pigment was of a brown colour, and the cells were apparently stained with it, the staining being of various degrees in depth, and frequently affecting not the whole but only a part of the cell. On examination, in the fresh state, it was particularly noticed that the pigment was not, so far as appeared, granular, but rather a simple brown staining. Both pigmented and colourless cells were the seat of fatty degeneration, and Dr. Coats was convinced that any appearance of separate pigment-granules, which might have been supposed to exist, was really dependent on fatty degeneration in the pigmented cells. The addition of liquor potassæ produced no perceptible alteration in the colour of the pigment, although by degrees destroying the cells.

Fatty Tumour of Uterus.—Dr. JOSEPH COATS showed the uterus in the case just detailed. It was normal in size, and its cavity was normal. In its posterior wall, towards the right side, a somewhat bulky tumour was felt, on cutting into which there was found an encapsuled growth about the size of a small hazel-nut. It had a yellow colour, suggestive of fat, but it was of rather firmer consistence, although by no means so firm as the ordinary myoma. It was buried in the muscular parenchyma of the organ. The appendages of the uterus were very much matted together, and the organ was adherent to the rectum behind but free in front. Douglas's space was occupied by a collection of melanoid growths similar to those of the peritoneum generally (see preceding communication), but of larger dimensions and exceedingly soft. The Fallopian tubes were hardly to be made out, buried as they were in multitudes of black growths, and obscured in their relations by adhesions. On the right side, what was supposed to be the ovary was occupied by two melanoid growths, one as large as a large hazel-nut, and the other a third of that size. It was not certain, however, that this was the ovary, and on the opposite side only apparent traces of the ovary could be made out. [This woman had been twenty-three years married without any family. The catamenia ceased at the age of 36, four years before her death, after a severe attack of rheumatic fever; for the details of fatal illness, etc., see above.] The microscopic examination of the uterine tumour showed in all respects the usual characters of the fatty growth; large fat-cells occurring in closely set aggregates, with some intervening fibrous tissue.

Vesical Calculus.—Dr. WM. MAC EWEN showed a calculus, weighing over eight drachms, removed by the lateral operation from a man aged 40. He had complained chiefly of pain in the hepatic region, but, on inquiry, it was found that he passed blood occasionally with his urine, and this led to the detection of the calculus by the sound; the wound healed completely in twelve days.

Urethral Calculi.—Dr. MAC EWEN also showed two calculi which had been removed from the urethra of a boy, having given rise to retention of urine. As they could not be removed by forceps, a valved incision was made, and both extracted by the same wound; in this way the wound in the urethra was subcutaneous; a catheter was kept in for some days, and in a fortnight he was well.

CORRESPONDENCE.

OUT-PATIENTS' MEDICAL RELIEF.

SIR,—Assuming that the main difficulty in the way of out-patient reform relates to the business of discriminating between those who can and those who cannot afford to pay for medical advice upon the very easy terms of provident dispensaries, it seems pertinent to observe that the special knowledge needed for this task, as well as the place where the selection can be best made, should be sought for not within the hospital, but away from it.

Such, indeed, is the theory upon which letters of recommendation were originally issued, a theory which assumes that each subscriber will institute due inquiry as to the means and needs of applicants before making petition (for "a letter" is no more than that) on their behalf.

The theory fails because it assumes too much. This intelligent scrutiny is not really exercised, nor is the letter taken as a request, but as a demand. Of all modes of admission, this has come to be the worst.

But the principle is right nevertheless, only its machinery is defective. Hospital letters (good in so far as they relieve hospitals of a duty they have no means of performing) might be made wholly good if the discrimination and care in their bestowal which we now assume were actually secured, and those to whom they are entrusted were required to give account of their trust. With this view, hospital letters should be dealt out by tender, yearly or half-yearly, upon certain specified

conditions. Charity organisations, ministers of religion, visitors of the poor, approved philanthropists, perhaps provident dispensaries themselves, should be so supplied on their own requisition: the conditions being that they would render to the hospital periodically, according to an approved form, a strict account of their stewardship. Subscribers, of course, would not be excluded from obtaining letters on the same terms; but the payment of a guinea would no longer secure as at present the right of pauperising the poor, or of obtaining, under the fair name of charity, medical advice for a large staff of workpeople or servants.

If some such plan were adopted by the general hospitals in London, the returns so obtained might be forwarded ultimately to some central organisation, which would thus be furnished with the means of estimating on a large scale the actual working of the present system of out-door medical relief.

Be the plan what it may, it is at least necessary to prevent indiscriminate crowds of sick from collecting in hospital waiting-rooms. Only last week, at the place where I sit and cure, there appeared among the number a little child in the desquamative stage of scarlet fever. She had been waiting some hours in these realms of fancy with other children, pretty closely packed, expecting, like the rest, her turn to be healed. If the gross result of that morning's work could be estimated, would it be good or bad?

With the ignorance of the poor, with the impotence of drugs, with the dangers incident to long waiting and exposure in bad weather, with the impossibility, under *any* system, of determining beforehand which should come and which should stay away, out-patient practice is beset with evil. Yet, so long as the public will have it so, we can but seek to minimise this evil. And, indeed, until we are persuaded that our work as assistant-physicians is, on the whole, beneficial, it seems premature, if it be not impossible, to determine, as is now proposed, a scale of recompense.

Your obedient servant,

OCTAVIUS STURGES.

SIR,—I have read with much satisfaction the extracts from the report of the Royal Free Hospital on the above subject, and your comments thereon. Believing, with you, that some may feel "the Royal Free is not a fair example of the General Hospital, because it requires no governors' letters of recommendation", I think it may be of value to reproduce the results of an inquiry made by the Charity Organisation and Mendicity Society, in the latter part of 1873, into the circumstances of the patients attending a large provincial general hospital—the Queen's Hospital, Birmingham—where the ticket system was and is in force. Having myself had a good deal to do with the conduct of this inquiry and the mode of operation adopted, I can fully confirm the thoroughness and accuracy of the information obtained. The chairman of the Charity Organisation and Mendicity Society, the Rev. J. C. Blissard, devoted a large portion of his time and attention to the investigations made; and, in addition, the assistance of some of the foremen of the largest manufacturing firms in Birmingham was secured, who displayed much interest in the inquiry. The results of this investigation may be briefly summarised thus:—

Cases investigated.—In-patients, 88; out-patients, 366. Total, 454.
In-patients. Ticket cases: false addresses, 5; cases unsuitable, 6. Free cases: emergency and accident cases able to contribute towards maintenance, 8; emergencies, unsuitable, 2; leaving legitimate objects of charity, free and ticket cases, 67; total, 88.

Out-patients (all ticket cases):—Information refused, 2; false addresses, 34; parish cases, 6; unsuitable, 64; legitimate, 260. Total, 366.

It will thus be seen that, of the in-patients, 10 per cent. were found to be unsuitable cases, and of the out-patients 64, or nearly 20 per cent., were rejected on the same ground. It will further be observed that three-fourths of the unsuitable in-patient cases were admitted by ticket, thus clearly showing that the free system is far less abused in practice than the ticket; and this view will be further confirmed when the above figures are compared with those published in reference to the inquiry at the Royal Free Hospital. I ought, perhaps, to mention that in this inquiry "cases of severe disease, such as epilepsy, hypochondria, etc., and some cases of venereal disease, independently of the patients' pecuniary circumstances", and also "cases of chronic or prolonged illness, where the patient had previously paid for medical advice in adequate proportion to his means", were classed as legitimate. It may be well to give samples of each class of cases, as taken from the list published in the report.

Legitimate Cases.—No 339. A parish case passed as legitimate, because she had previously been attended for three months by the parish doctor, but without obtaining much benefit.—No. 44. Comfortably off when able to work. Passed, because husband's earnings were stopped by reason of his poisoned hand.—No. 189. Young woman,

whose family earned good wages. Passed because she had been ill a long time.

Cases of Imposition.—No. 76. Married man, aged 50; wife and one daughter, aged 20, at home. Keeps a thriving public-house twenty miles from Birmingham; has a large yard and out-premises, and is a dealer in hay and straw. Comes into Birmingham on Thursdays for business, and takes the opportunity of going to the hospital.—No. 214. An elderly lady, whose son lives out of Birmingham, but has a large manufactory in the town.

Unsuitable Cases.—No. 36. Youth, aged 15. Lives with father and mother. Earnings of family 30s. per week. The other children married or in service.—No. 88. Married man, aged 24. Wife and one child. Is a painter; has left his wife, and is a drunkard.

I think these instances will suffice to show on what grounds cases were accepted or rejected. In conclusion, I may state that the report strongly recommends the abolition of the present method of issuing tickets in return for subscriptions, and the adoption of the free system—the one in use at the Royal Free Hospital. No one who has watched the working of these two systems carefully can doubt that the sooner the free system, with the addition of a provident dispensary on the Devonport or some similar plan, is adopted universally by the committees and governors of our medical charities, the better will it be for the hospitals, the patients, and the public generally.

I am, yours faithfully, HENRY C. BURDETT.

London, March 27th, 1875.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Monday, April 5th.

The Army Medical Service.—In Committee of Supply, on the vote of £248,700 for medical establishment and services, Mr. DUNBAR pressed Mr. HARDY to give the committee some assurance that the system of promotion and pay of medical officers would, on an early day, be taken into careful consideration, as at present it did not give satisfaction.—Mr. HARDY said the differences of opinion as to what the grievances of these officers were, made it a difficult thing to deal with the matter. He had been deluged with pamphlets written on one side or the other of the subject, by gentlemen of considerable eminence. There were, however, certain points with regard to which he thought he should be able to grant some of the desired advantages. The vote was agreed to.

The Contagious Diseases Act.—On the vote of £368,700 for the Commissariat and Ordnance Store Establishment and wages, Mr. GOURLEY proposed to reduce the vote by the sum of £4,750, the police expenses in carrying out the Contagious Diseases Act.—Mr. G. HARDY said that it was impossible to bring in the army estimates without including the item to which the hon. member objected. So long as the Act remained in force his was a purely administrative duty, and he could not exercise any control in the matter. The question would be raised on another occasion, and then he should be prepared to express his opinion upon it. It would be absurd to pass an Act which could not be carried out without the payment of money, and then to refuse to grant the sum necessary for the purpose.

Unhealthy Barracks in Ireland.—On the vote of £759,700 for works and buildings at home and abroad.—Colonel ALEXANDER called attention to the unhealthy state of the barracks in Ireland, especially Beggar's Bush, Island Bridge, and Richmond Barracks. Although they were reported on so long ago as 1872, nothing had been done up to this time to remedy the water-supply. He also asked when it was proposed to erect a separate building in Dublin for the treatment and isolation of soldiers' families suffering from contagious diseases. He was glad to find that the huts at the Curragh were to be renewed, and he hoped the same would be done at Beggar's Bush Barracks. In the past winter, two officers of the 3rd battalion of Guards succumbed to the attacks of typhoid fever, caught whilst stationed at Beggar's Bush barracks. After several minute inspections of the state of the barracks, it was at last discovered that the drains were in a most wretched state, and were no doubt the origin of the disease that prevailed there.—Lord C. J. HAMILTON said that, having been formerly stationed in Ireland, he could say that the state of Island Bridge Barracks, Richmond Barracks, and Beggar's Bush Barracks had become a public scandal. They were little better than pest-houses, and he hoped the Secretary of State for War would give his earnest attention to the matter, in order that it might be remedied.—Sir H. HAVELOCK was glad to find that money was to be applied to the amelioration of married soldiers' quarters in various parts of Ireland. He had seen ten married families in two rooms, consisting of between thirty-five and forty

individuals in each room, with no separation between them. Kilmainham Barracks were in a very unsanitary state.—Colonel MURE said that, when an inspection was made at Beggar's Bush Barracks, it was found that it would only cost £15 to put them in a proper sanitary condition, yet that small sum had been refused, because the department did not wish to alter the army estimates at the last moment.—Mr. HARDY was quite sensible of the distressing nature of the circumstances that had occurred at these barracks, but was not prepared to conclude that the illness of the officers there was due to the causes which some persons assigned. With respect to the private soldiers, they were in perfect health. As soon as his attention was called to the subject, he directed an inquiry to be made on the spot. As the hon. member for Devonshire had given him notice of a question bearing on this matter, he would defer giving full particulars.

Miscellaneous Votes.—The following sums were voted for the ensuing year in Committee of Supply:—Science and Art Department, Great Britain, £1,600; Local Government Board, £116,000; Lunacy Commission, £2,500; General Register Office, £7,500; Broadmoor Criminal Lunatic Asylum, £5,000; Learned Societies, £2,000; University of London, £1,600; Lunacy Commission (Scotland), £1,000; General Register Office (Scotland), £1,100; Board of Supervision, £13,300; Scotch Universities, etc., £3,000. For Ireland: Local Government Board, £18,300; General Registrar Office, £3,100; Pauper Lunatics, £20,000; Dundrum Criminal Lunatic Asylum, £1,000; Queen's University, £700; Queen's College, £700; Hospitals and Infirmarys in Ireland, £3,100.

Tuesday, April 6th.

Beggar's Bush Barracks.—Mr. HARDY, in reply to Sir L. Palk, said he had no official knowledge of a report on the sanitary state of the barracks in 1873, though he had no reason to doubt that some such report was made. In December 1873, the officer of the Royal Engineers asked permission to remove the cesspits, and they were done away with, and the privies in the rear of the mess premises and barrack-sergeant's quarters were converted into water-closets by March 1874. He regretted to say that there were several deaths from scarlet and typhoid fever in 1873, especially of children. The report of the Medical Officer of Health for 1874 said, "The general health of the troops has been good during the period specified. The Grenadier Guards have not been so healthy for the past twenty years." No cause of disease could now be found in the barracks, but additional ventilation for the drains had been authorised, and the Army Sanitary Committee would inspect the place on April 12th.

Small-pox in Ireland.—Sir M. BEACH, in reply to Captain Nolan, said he was not able to inform the House how many cases of small-pox had occurred since the 1st of October in the counties of Galway and Mayo. Certain offenders had been sentenced to six months' imprisonment for violating the law, by practice of inoculation, and he hoped that that sentence would have a salutary effect. With respect to the general prevalence of small-pox in Ireland, he was happy to say that it had lately decreased.

The second reading of the Mercantile Marine Hospital Service Bill has been deferred till Tuesday next, the 13th instant.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

The Sheffield Board of Guardians have increased the salary of Mr. George H. Shaw, medical officer for the Attercliffe District, from £60 to £100 per annum.

VACCINATION.—Mr. George O. Kell, the vaccination officer for the Winsford district, has been awarded, by the Local Government Board, the sum of £16 11s., for efficient vaccination. This is the second award of the kind which he has received.

EFFECTS OF SEWER-GAS.

DR. SAUNDERS, medical officer of the combined rural sanitary districts of Hertfordshire, writes to us: The paper of Dr. Fergus, to which you drew attention in last week's JOURNAL, on the effects produced by sewer-gas, is a further evidence of the great necessity for casting aside all dependence on "traps", and of making provision for the inevitable sewer-gas finding its way into the external atmosphere on one or other side of the soil-pipe connection, in such situation as it shall be harmless.

There is one point of the soil-pipe, using that term to convey the

idea of the pipe leading from the closet-pan to the sewer, which needs ventilating as much as any other, and yet, in the ordinary way in which a ventilating shaft is put in, escapes; I mean that which is technically known as the "container", the portion of the pipe, *i.e.*, immediately above the D trap. This D, or syphon-trap as the case may be, contains water through which all the fæces must pass, and, consequently soon becomes exceedingly foul; the discharge of water taking place each time the closet plug is pulled not being nearly sufficient, in nine times out of ten, to change the contents of the trap and leave fresh water behind. The trap consequently becomes corroded as Dr. Fergus showed the soil-pipes to do, its capacity is lessened by deposit of urinary salts, it offers obstruction to the free and rapid passage of fecal matter, and, holding less water, acts less efficiently as a trap to the soil-pipe below. Every water-closet, therefore, should be provided with some means by which a definite supply of water, equal at least to the capacity of the trap, should be discharged each time the closet plug is pulled. Messrs. Grist and Grimes have patented such an arrangement, and I have had it used with the best results. The other essential point, to which I wish to direct especial attention, is the additional ventilation, by a small (one inch) pipe, of the closet "container". This may be carried to an outside wall, and cut short, taking care that it is not immediately under a window; or, if the ventilating pipe of the soil-pipe proper, be near at hand, it might open into it, but I do not think this necessary. This small ventilating pipe then gets rid of the offensive gas from the never-wholly-changed water in the trap (a miniature cesspool), and should the trap, as is too frequently the case, be incompetent, it provides an outlet for the sewer-gas to the external air, instead of into the water-closet and dwelling.

POOR-LAW MEDICAL APPOINTMENTS.

BERNARD, Armand, M.B. Dubl., appointed Medical Officer for Nos. 7 and 8 Districts of the Parish of Liverpool.
 BOLTON, John A., L.R.C.S.I., appointed Medical Officer and Public Vaccinator for the Coniston District of the Ulverston Union, *vice* J. H. M. Galwey, resigned.
 COLMAN, Thomas J., M.D., appointed Medical Officer of the Third District of the Clifton Union, *vice* R. G. Fendick, M.R.C.S., resigned.
 DOWNING, E. H., Esq., appointed Medical Officer for the South Deptford District of the Greenwich Union, *vice* T. D. Parker, Esq., deceased.
 ELLIS, E. T. C., Esq., appointed Medical Officer for the Third A District of the Hailsham Union, *vice* W. Press, Esq., resigned.
 FAIRWEATHER, A. F. A., Esq., appointed Medical Officer to the Second Pocklington District and Workhouse, *vice* R. E. Deane, L.R.C.P., resigned.
 FOX, Edward C., M.D., appointed Medical Officer for the Newton Poppleford District of the St. Thomas Union, Exeter.
 GAY, John H., M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for the Spilsby East District of the Spilsby Union, *vice* J. Thimbleby, L.R.C.P. Ed., resigned.
 HAYDEN, W. G., Esq., appointed Medical Officer to the Workhouse of the Wycombe Union, *vice* Bowstead, Esq., resigned.
 RUCKLEY, H. R., Esq., appointed Medical Officer to the Third District of the Wycombe Union.
 OSBALDESTON, L. F., M.R.C.S., appointed Medical Officer to the Third District of the Hatfield Union.
 FENRICE, David S., M.R.C.S. Eng., appointed Medical Officer and Public Vaccinator for No. 2 District of the Henstead Union, Norfolk, *vice* A. C. T. Findlay, M.D., resigned.
 ROBERTS, C. H., Esq., appointed Medical Officer for the Workhouse and the Fourth District of the Alderley Union, *vice* F. C. Bennett, Esq., resigned.
 SINCLAIR, John, M.D., appointed Medical Officer for No. 10 District of the parish of Liverpool.
 SMYTH, H., Esq., appointed Medical Officer to the Second District of the Poole Union, *vice* A. Crabb, M.D., deceased.
 WAUGH, John, Esq., appointed Medical Officer to the Toddington District of the Woburn Union, *vice* W. T. G. Helps, Esq., resigned.

MILITARY AND NAVAL MEDICAL SERVICES.

REDUCTION IN THE NUMBERS OF ARMY MEDICAL OFFICERS.

THE statement of the Secretary of State for War, in reply to questions asked by Dr. Lyon Playfair, that there are now no vacancies in the ranks of the army medical department, but, in fact, at the time he spoke that there were seven officers in excess of the established number, has called attention to the reduction that must have been made in the strength of the establishment of this branch of the public service. Strangely enough, the numbers of officers of the army medical department shown in the annual estimates of the War Department laid before Parliament do not seem to indicate any such reduction. But, on reference to the monthly army lists, it will be seen that during the past twelve months thirteen medical officers of different ranks have been lost to the service from death, while forty-two have retired on half-pay, one has resigned his commission, and two have been transferred to the African service. This makes a total of fifty-eight officers

who have disappeared from the active lists of the department. On the other hand, during the same period, only seven officers have been brought in from half-pay, one transferred from the African to the general service, and twenty-four fresh appointments made. Thus there are now twenty-six army medical officers less than there were a twelvemonth ago. This reduction implies a considerable saving in money to the Government; and, as it also entails a greater amount of work on the medical officers, it entitles them to ask for additional compensation. The chief point is, however, that there ought to be no difficulty in ascertaining what the fixed number of army medical officers in each rank of the service is; and there is at present a great difficulty in reconciling the statement on this head by the Secretary of State for War with the statement set forth in the Army Estimates. Can it be that Mr. Hardy, in speaking of the number of medical officers being in excess, refers to an excess over the number which he intends to be that of the future establishment of the army medical service? If so, the contemplated future strength of the department ought to be made known. At any rate, it is clear that the strength on the full-pay list has been reduced by twenty-six officers during the past twelve months.

NAVAL MEDICAL APPOINTMENTS.

BLAKE, Surgeon F. W., to the Royal Marine Artillery Division at Portsmouth.
 DICK, Surgeon James N., additional, to the *Fisgard*.
 MACCLINTON, Surgeon W. F., to the *Duke of Wellington*.
 NEGUS, Surgeon Fysher, to the Portsmouth Dockyard.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF CAMBRIDGE.

SCHOLARSHIPS IN GONVILLE AND CAIUS COLLEGE.—The Open Scholarship in Natural Science at this College, of the annual value of £60, has been adjudged to Edmund J. Legg of Dulwich College.—*Proxime accessurum*.—W. Wellington Lake, St. Thomas's Hospital; William Stone, Clifton College. In consequence of the indisposition of Dr. Drosier, senior fellow, Dr. Bradbury has, for the present undertaken the duties of medical lecturer in the College.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners on the 6th inst., and, when eligible, will be admitted to the pass-examination:

Messrs. William J. Cant, Charles L. Williams, Alfred Pratt, and Cordley Bradford, students of the Birmingham School; Percy A. Steedman, Thomas H. Gillam, Alexander R. Anderson, and Ernest H. Walter, of St. Bartholomew's Hospital; William J. Pycock, B.A. Cantab., and Edward J. Wood, B.A. Cantab., of the Cambridge School; Henry J. D. Innes, and Oscar Tottie, B.A. Cantab., of St. George's Hospital; Henry Davey, and Frederic H. Berry, of Guy's Hospital; Edward S. Morgan, and Arthur Hemsted, of University College; Basil H. Walker, John G. Clark, and Major Greenwood, of the London Hospital; Gilbert S. Griffiths, and Thomas James, of the Middlesex Hospital; Graeme B. Fraser, and William L. Cox, of St. Mary's Hospital; Bernard J. Newmarch, of King's College; Wm. L. O. Williams, of the Glasgow School; Joseph Wigglesworth, of the Liverpool School; Francis F. Willis, of the Manchester School; Clarke K. Morris, of St. Thomas' Hospital; Robert N. Hartley, of the Leeds School; Hayward Whitehead, of the Charing Cross Hospital; and Cecil Henderson, of the Bristol School.

The following gentlemen passed on the 7th inst.:

Messrs. James Rose, William Gillibrand, Walter Barber, and Roger H. Jones, of the Liverpool School; Hamilton Lighten, B.A. Cantab., Thomas E. Morgan, and George R. Turner, of St. George's Hospital; William M. Hope, William J. Frankish, and Edwin Hughes, of University College; John C. Chithoff, John W. Meek, and Peter Horrocks, of Guy's Hospital; George H. Sidebotham, John Ferguson, and Albert Andrew, of the Manchester School; Frederick W. Giles, and John H. Battye, of St. Thomas's Hospital; Cesar F. Hawkins, and Edward Berdoe, of the London Hospital; Walter J. Milles, and Edgar Thurston, of King's College; Robert H. A. Schofield, and William J. Haines, of St. Bartholomew's Hospital; William Leah, of the Birmingham School; Frank S. Boreham, of the Charing Cross Hospital, and Frederick Bellaby, of the Middlesex Hospital.

The following gentlemen passed on the 8th inst.:

Messrs. William Dunstan, William Lane, John Morgan, Edward C. Greene, and Joseph Hammersley, of Guy's Hospital; Thomas E. F. McGeagh, James J. Jones, James W. Browne, and Frederick L. Benham, of University College; Charles E. Sheppard, Robert J. Mills, Francis H. Weekes, and George W. Robinson, of St. Thomas's Hospital; Harold G. Taylor, Frederick De Caux, Edmund H. Howlett, and Arthur G. Blainfield, of King's College; Percy Kidd, B.A. Oxon., William B. Clarke, Thomas Wilmot, and Edward E. Cripps, of St. Bartholomew's Hospital; William F. Jusseum, Charles J. R. Owen, and Henry L. Webb, of St. Mary's Hospital; Arthur Bennett, Robert E. Inman, and Charles A. S. Ling, of the London Hospital; Hardwick Le Cramier, and Francis Goodchild, St. George's Hospital; and Samuel A. Clinton, M.D., New York, and Arthur R. Davis, of the Middlesex Hospital.

MEDICAL VACANCIES.

THE following vacancies are announced:—

- AMMINSTER UNION**—Medical Officer and Public Vaccinator for the District comprising the southern parts of the Parishes of Membury and Chardstock. Salary, £23:6:8 per annum, and fees. Applications on or before the 14th inst.
- BARTON-UPON-IRWELL UNION**—Medical Officer for the Cadishead District. Salary, £25 per annum.
- BETHLEM HOSPITAL**—Two Resident Medical Students.
- BOLTON UNION**—Medical Officer for the Horwich District. Salary, £30 per annum.
- BRADFORD INFIRMARY AND DISPENSARY**—Physician. Applications to be sent on or before June 12th.
- BRADFORD MEDICAL AID ASSOCIATION OF FRIENDLY SOCIETIES**—Surgeon. Salary, £200 per annum, with fees, house, gas, etc. Applications on or before the 21st instant, to Mr. W. B. Cawthra, 18, Newington Street, City Road, Bradford.
- BRISTOL ROYAL INFIRMARY**—Dispenser. Salary, from £100 to £120 per annum. Applications on or before the 14th instant.
- BURTON-ON-TRENT UNION**—Medical Officer for the Etwell District. Salary, £70 per annum.
- CALNE UNION**—Medical Officer. Salary, £200.
- CHELtenham GENERAL HOSPITAL AND DISPENSARY**—Honorary Medical Officer at the Branch Dispensary. Applications on or before the 17th instant.
- DOVER UNION**—Medical Officer for the St. Mary's District and the Workhouse. Salary, £150 per annum.
- DUNDEE ROYAL INFIRMARY**—Resident Medical Superintendent. Salary, £200 per annum, with board, lodging, and washing. Applications on or before the 21st instant.
- GRAVESEND AND MILTON UNION**—Medical Officer for the Milton District. Salary, £70.
- HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST**, Brompton—Two Physicians. Applications on or before the 14th instant.
- LIVERPOOL ROYAL INFIRMARY**—Resident Medical Officer. Salary, £100 per annum, with board, lodging, and washing. Applications on or before April 10th.
- METROPOLITAN FREE HOSPITAL**, Devonshire Square, City. Assistant House-Surgeon. Applications on or before the 12th instant.
- MILFORD UNION**, co. Donegal—Medical Officer for the Ramelton Dispensary District. Salary, £100 per annum, and fees.
- NEWBURY UNION**—Medical Officer for the Fifth District.
- NEWMARKET UNION**—Medical Officer for Nos. 1 and 3 Districts. Salary, £85 per annum.
- ORTH BIERLEY UNION**—Medical Officer for the Workhouse. Salary, £90 per annum, and fees. Applications on or before the 13th instant.
- ROYAL INFIRMARY FOR WOMEN AND CHILDREN**, Waterloo Bridge Road—Physician.
- SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY**—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.
- SOLIHULL UNION**—Medical Officer for the Solihull District. Salary, £44 per annum.
- TORRBY INFIRMARY**—House-Surgeon. Salary, £100 per annum, with board and lodging.
- WIRRAL UNION**—Medical Officer for the Upton District. Salary, £50.
- WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL**—House-Surgeon. Salary, £100 per annum, with board, washing, and furnished apartments. Applications on or before May 31st.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

- CARTER**, Charles H., M.D., appointed Physician to the Hospital for Women.
- COLLINS**, Walter H. G., M.B., appointed Assistant House-Surgeon to the Swansea Hospital.
- CROMMING**, Hugh G., F.R.C.S. Eng., appointed House Surgeon-Apothecary to the Devon and Exeter Hospital, vice E. J. Donville, L.R.C.P., resigned.
- HEARN**, Richard T., M.B., appointed House Surgeon to the Dorset County Hospital, vice H. B. L. Smith, M.B., resigned.
- HOLLAND**, Edmund, M.D., appointed Assistant Physician to the Hospital for Women.
- LEBARRI**, Henry A., M.B., appointed Medical Officer to the Central London New District Sick Asylum, Cleveland Street.
- OBEL**, M. D. C. G., M.B., appointed Assistant Medical Officer to the Durham County Lunatic Asylum, Sedgfield.
- PARKHOUSE**, Henry, M.R.C.S., appointed Senior Resident Medical Officer to the Killarney Dispensary, vice S. T. Cass, L.F.C.P.L.D., resigned.
- PARKES**, Alfred, M.R.C.S. Eng., appointed House-Surgeon to the District Hospital, West Bromwich, vice J. Johnston, M.B., resigned.
- REID**, Watson, M.B., appointed Resident Medical Officer and Secretary to the West Norfolk and Lynn Hospital, vice C. I. Priestley, L.R.C.P.L.D., resigned.
- SARTH**, Richard T., M.D., appointed Assistant Physician to the Hospital for Women.
- TOWNR**, A. S., M.R.C.S. Eng., appointed House Surgeon to the Seamen's Hospital, Greenwich, vice J. Glanville, M.R.C.S. Eng., resigned.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

MARRIAGE.

- COWLES-BALFES**.—On the 6th instant, at East Parade Chapel, Leeds, by the Rev. F. R. Conder, M.A., W. R. Gowers, M.D., of 10, Queen Anne Street, Cavendish Square, London, to Mary, second daughter of Frederick Baines, Esq., Westwood Lodge, Leeds.

DEATH.

- TYLER**.—On February 28th, at South Bank, Wedmore, Somerset, Elizabeth, the dearly beloved wife of Richard Funnell Tyler, M.D., and only surviving daughter of Joseph Wollen, Esq., J.P., aged 38.

OPERATION DAYS AT THE HOSPITALS.

- MONDAY**.....Metropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- TUESDAY**.....Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY**..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- THURSDAY**....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.
- FRIDAY**.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.
- SATURDAY**....St. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- MONDAY**.—Medical Society of London, 8 P.M. Mr. Churton, "A Case of Accumulation in the Ascending Colon, followed by Spasm of Larynx, in an Infant"; Dr. Edwards Crisp, "On Group and Diphtheria, with recent illustrative Cases"; Staff-Surgeon L. H. J. Hayne, R.N. (communicated by the Secretary), "An Account of an Epidemic of Enteric Fever which occurred on board H.M.S. *Doris* in the West Indies in 1873".
- TUESDAY**.—Royal Medical and Chirurgical Society, 8 P.M. Ballot.—8.30 P.M. Mr. Acton, "On the Comparative Prevalence and Severity of Syphilis among Troops in London, Paris, and Brussels".
- WEDNESDAY**.—Epidemiological Society, 8 P.M. Dr. Seaton, "On the International Sanitary Conference at Vienna".—Hunterian Society, 8 P.M. Dr. Pye-Smith will introduce the subject of Hodgkin's Disease (Leukæmia).
- THURSDAY**.—Harveian Society, 8 P.M. Mr. George Field, "Cases in Aural Surgery".

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

M. S.—We do not advise on such subjects. Any respectable practitioner may be consulted.

TAR PILLS.

SIR.—With reference to Mr. R. R. Cheyne's query in your last week's JOURNAL, I beg to inform your readers that tar can most conveniently be made into pills by the following formula:—Take of tar two grains; Iycopodium one grain; mix to make one pill. These proportions form a mass which can be moulded into pills readily, but the mass improves and becomes firmer if kept a few days before rolling out. Two parts of liquorice powder, added to three parts of tar, make a tolerably good mass. Flour, as recommended by Dr. Garrod, does not answer well. But the most elegant and palatable form of administering tar is that of the gelatine globules (containing on an average about two and a-half grains in each), prepared by M. Thevenot, of Dijon. They have no odour, are perfectly soluble, and can readily be taken by the most fastidious.

While on the subject, I desire to add a word of caution about the use of calcined magnesia as an excipient for forming tar into pills. One part of it added to three parts of tar makes a soft mass, which soon hardens, and can be moulded into pills. Pharmaceutically, they are all that can be desired, but the creasote and resinous acids contained in tar form compounds with magnesia, which are so insoluble that they are passed by the patient undissolved. They can even be boiled in water without losing much of their globular shape. The same remarks apply to creasote itself—many dispensers find a little calcined magnesia, or slaked lime, answers admirably for this substance in forming it into pills, but if genuine creasote be used, the pills so made are as insoluble as marbles.—I am, Sir, yours faithfully,
10, New Cavendish Street, W., March 29th, 1875. WM. MARTINDALE.

MR. GLISSAN (Brynmaur).—A man holding the single qualification M.R.C.S.E., 1857, cannot legally charge for attendance and medicines in purely medical cases. No one can prevent him from attending medical cases, but he cannot receive payment for such attendance.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

AN APPEAL.

SIR.—An appeal is earnestly made on behalf of the widow of the late George D. Dermott, the well known lecturer at the School of Anatomy, in Charlotte Street, Bloomsbury.

Mrs. Dermott is 73 years of age, and is suffering from defective sight and many bodily infirmities, which require more attendance and comforts than the small income she possesses can procure. It is, therefore, hoped that by the liberality of the profession, and especially of the friends of her late lamented husband, a sum may be raised which will be sufficient to place her, for the brief remainder of her life, in more comfortable circumstances.

Thirty years have now passed away since the death of Mr. Dermott, but doubtless there are many of his pupils still living, who on noticing this appeal, will willingly add their contributions. The following sums have been promised:

Sir W. Jenner, Bart.	£5 5 0
Sir H. Thompson	1 5 0
Dr. Dow, Bayswater	1 1 0
Dr. George Ross, Bloomsbury	2 2 0
J. Roche Lynch, Esq., Notting Hill	2 2 0
W. M. B. C.	1 1 0

Further contributions will be thankfully received and acknowledged by Dr. George Ross, 11, Hart Street, Bloomsbury; or by the undersigned,

J. ROCHE LYNCH, L.R.C.P. (Lond.).

41, Chepstow Villas, Notting Hill, W.

MR. VAN H.—You will find a long and interesting account of Evolution of Light in the Human Subject, by Sir Henry Marsh, in the *Dublin Journal*, vol. xxii, page 133.

FEES FOR POLICE CASES.

SIR.—Your powerful advocacy of the cause of medical men against the tyranny of magistrates and others, encourages me in bringing before you the following case, which, in my opinion, ought to be made public, in order to be a lesson to others. At the end of December last, I was house-surgeon to the Carmarthenshire Infirmary, which post I had held for eighteen months. A few days before my leaving, I was asked by the police to give evidence in the case of a woman who had been under my care in the Infirmary. Having taken the precaution to be summoned by the superintendent in the usual way, I attended at the court and gave my evidence. A day or two afterwards, I called at the clerk's office for the fee, and was told by his deputy that I was entitled to a fee, but that there was none ordered. He then said he would bring the matter before the magistrates at their next sitting, and asked me to call again. I did so, and was this time requested to make an application in writing for it. As I was on the point of leaving the town for London, I made that application from here. After having waited for an answer for more than a fortnight, I wrote again to the clerk, telling him what I had done, and renewing the application. After another considerable delay I received a letter, dated February 13th, 1875, enclosing another letter dated February 6th, 1875, which had been misdirected. In the latter, I was informed that "It is not usual to allow any fee for attending as a witness in police cases if the witness live in town," but that the case would be mentioned to the bench, etc. In the other letter (February 13th), I was told that the case had been mentioned, and that "they decided to make an order."

On the advice of a medical gentleman of considerable experience in these matters, I wrote to the Secretary of State, enclosing a copy of the correspondence. I received a reply that the subject would be "fully considered." A few days later I received another letter, stating that the Secretary of State had "no power to order such fee to be paid." That is the whole of the case, and it speaks for itself. The amount of the fee is insignificant compared with the principle involved. What greatly aggravates matters, is the fact that two of the magistrates for the borough of Carmarthen are medical men.—Yours truly,
RICHARD WILLIAMS.
22, Percy Circus, W.C., March 23rd, 1875.

PSYCHOLOGIST.—Our immortal Shakespeare truly says:

"Grief best is pleased with grief's society:
True sorrow, then, is feelingly surprised
When with like feeling it is sympathized."

USE OF SAL AMMONIAC.

SIR.—Will any of your correspondents favour me with their experience of the use of ammonium chloride (sal ammoniac, NH_4Cl)? I have used it in cases of flatulent distension of the stomach and upper part of the alimentary canal, combining it with dilute nitro-hydrochloric acid (minims to 15), and have apparently had good results in many cases, when the acid alone failed to give relief. The dose I usually give is fifteen grains two or three times a day. I have found it most useful in those cases where there has been a furred tongue, with enlarged and irritable circumvallate papillae, with more or less constipation of the bowels, tasteless eructations, and what patients call a "stomach-cough." It appears to act slightly as a cholagogue, increases the mucous secretion of the bowels, and allays the irritable cough which is often present in cases of dyspepsia, when no physical signs of bronchial or laryngeal irritation can be heard. It appears to me to be useful in those cases of dyspepsia which are brought on by excessive smoking, and which are very numerous in the practice of
A YOUNG DISPENSARY SURGEON.

F.R.S.—Mr. Frank Buckland is a son of the late Dean of Westminster, and a member of the College of Surgeons.

E. R.—It was Terence who said, "Nostre virgines—si bono habitu sunt, matres pugiles esse aiunt, et cibum deducunt." In some countries, however, moderate obesity is considered a beauty. If *embonpoint* is generally a sign of good humour and a cheerful disposition, "scrappiness" frequently betokens a sour, crabbed, and ill-natured character. Solomon has said, "A merry heart doeth good like medicine, but a broken spirit drieth the bones."

ASSOCIATE, KING'S COLLEGE.—The portrait of Sir William Fergusson is now in the possession of the College of Surgeons: the engraving from it is finished, and we believe that subscribers will receive their copies shortly. Write to Surgeon-Major Logie, Knightsbridge Barracks.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

TINCTURE OF CAPSICUM IN THE TREATMENT OF "TIPLING".

A CORRESPONDENT of *Land and Water* throws out some suggestions to alleviate, if not cure, "tipping in private life." He says: Of course, as a rule, moral means, such as persuading or frightening the patient, are futile. Dr. Ringer, in an able article in the *BRITISH MEDICAL JOURNAL* in 1871, advocated the use of capsicum, "given in doses of the tincture (ten drops), or the powder, twenty grains to be taken before meals, or whenever depression or craving for alcohol arises." It also induces sleep in early stages of delirium tremens. It obviates the morning vomiting, removes the sinking at the pit of the stomach, the intense craving for stimulants, and promotes appetite and digestion. This treatment I have tried with great success in several cases, and in one in particular, that of a young man, whom no one by any means in their power could possibly keep from tipping. Shut up the spirits, he had a key made on the quiet, while his wife was away for a day—of course he sent her. Take away his money, he would "tipple" on credit. He came under my care for bronchitis. I soon heard of his propensity, and tried Dr. Ringer's treatment. I began by giving him five drops of the tincture in a little syrup of orange-peel, and some orange bitters, and increased the dose of capsicum to twelve drops. He no longer to be seen in a half-muddled state, hanging about the low cabarets and taverns by himself, but every day walking out with his wife, and taking an interest in all that was going on. He left here for England about three months afterwards, and I have since heard that he still takes to his bottle (the capsicum bottle) whenever he feels inclined to indulge in the other sort of "tincture." Another case was that of a lady, over forty years of age, but not so successful as the one above cited. Of course, it is a great thing to wrap up the capsicum in a convenient vehicle, and the above suggested to me by M. Dutertre, the well-known pharmacist of our town, is, I think, as good a form as any.

AN OLD MEMBER.—There are fine collections of medical portraits in the possession of the College of Surgeons and the Royal Medical Chirurgical Society, the nucleus of which was collected by the unfortunate Mr. Fauntleroy, the banker of Berners Street, who was hanged at the Old Bailey for forgery.

MATERNAL IMPRESSIONS.

A FEW years ago, I attended a Mrs. S., wife of the manager of an equestrian troupe then exhibiting here—herself an active, wiry, and exceedingly clever horsewoman. I was with her nearly all night. Her delivery was very painful and difficult, owing to curious malformations of the two upper extremities. It was a footling presentation and a first child. The child, a male, was delivered alive, and some time since the mother informed me that it was an interesting, clever child, now being reared and educated in a private establishment. The child was healthy and well-developed, with the following exceptions: the nose, that is, the alae and point of the nose, was of a rosy-red, looking as if carefully painted; this did not appear to spoil the face, which might be pronounced handsome. The forearm of one upper extremity terminated abruptly about an inch below the elbow-joint, and ended in an index finger, capable of perfect flexion and extension. The other upper extremity terminated, also abruptly, exactly midway between the shoulder and elbow-joint, and was likewise completed with a perfect index finger. It was the shape of these limbs that caused all the difficulty and pain, and puzzled me much when delivering her. I am not aware of any of the other women of the troupe being similarly or at all impressed. I think it likely that it is only certain women can be impressed, and that at some certain period of utero-gestation. I have met with cases of face-marks, etc., which the mothers traced to some particular circumstance that shocked or impressed them when pregnant, but these are not new to any obstetrician. However, I will not go so far as a friend of mine, who once told me that such a lady was such a day delivered of a bouncing boy with a wooden leg, and a good iron ferrule thereon—because a neighbour whom she was in the habit of meeting had the misfortune to stamp about on such a contrivance.

Yours faithfully,
W. HENRY SANDHAM, M.R.C.S. Eng.
Cork, 20th March, 1875.

ACID DYSPEPSIA.

SIR.—In the *JOURNAL* of March 30, L.R.C.P. Edin., asks if any one can tell him some remedy for a case of acid dyspepsia which appears so far to have baffled him. I think I can help him in the matter if he will only adopt my suggestion, which is to give his patient small doses of dilute sulphuric acid, say three drops four times a day in a half wineglassful of water. I attach importance to its being given thus plainly and without any admixture of other drugs. I have treated with unflinching success several hundreds of such cases, whether arising from dyspepsia pure and simple, or complicated with cardiac disease. L.R.C.P. Edin. should remark the dose, which is probably smaller than he has ever used; but if he give the sulphuric acid in the ordinary doses, he will most likely find himself in the same predicament as a practitioner who recently was treating a patient with ten-grain doses of iodide of potassium three times a day, and noticing as a result, severe "cephalalgia" and "fluent coryza," was driven to inquire if any one can tell him "how he might obtain the therapeutical effects of the drug without producing such severe physiological action?"—I am, etc.

CHARLES R. FLETCHER,
M.D. (Exam.) Erlang., L.R.C.P. Lond.

P.S.—I have assumed that the diagnosis is correct when L.R.C.P. Edin. states that the pain after food arises from "intense acidity"; hence the influence with which I recommend sulphuric acid. Should the case, on the other hand, be one of "gastrodynia," from irritation of mucous membrane without any positive evidence of acidity, I would urge L.R.C.P. Edin. to give his patient ere nimis doses of liquor arsenicalis four times a day, half-an-hour after food, five grains of Bullock's pepsine directly after food will help. The patient should be prohibited from the use of solid food for a few days, giving instead, Prank's essence of meat, chicken-jelly, egg-yolk, etc. Stimulants are harmful.

MALARIA.

SIR.—Dr. Donaldson, in his letter to you, has, like many other of your correspondents, confounded things together, and reproached me with the confusion. It is not by any means the first time that I have been represented as saying certain things, and then made the butt of tiny shafts of small satire for propounding nonsense. I certainly have never, like Dr. Donaldson has done, confounded a contagious fever with one of so-called malarious origin. Most readers of army and other reports are aware that in hot countries there appear to arise, on one knows how, such formidable diseases as cholera, and that commonly called "yellow fever." Not having any definite information as to their nature, these complaints

have been—provisionally—attributed to "telluric" influences. But we recognise them as wholly distinct from acute and non-contagious remittents. We know that when once produced they spread both by infection and contagion, and reach parts of the globe wholly different from that from which they spring.

When the army or navy medical adviser has to manage either of these formidable complaints, he adopts, as far as possible, a plan analogous as that adopted at Labuan, mentioned by Dr. Donaldson. We do not yet know the original cause of typhus, typhoid, relapsing, fever, dysentery, variola, scarlatina, measles, leprosy, cholera, Asiatic and European, and in these days it is the endeavour of arm-chair philosophers to disentangle the innumerable involved threads of imperfect, insufficient and wholly worthless assertions, and to inquire into what is really the cause of such common complaints as catarrh, influenza, the fever spoken of as acute, and non-contagious remittents, as well as of the others before named. As I pointed out in a former note to you, we shall not arrive at a definite knowledge of any one of the causes which we seek to discover, by preferring "the rule of thumb" to the use of brains.

Dr. Oldham has pointed out, in a singularly practical book, that certain causes are capable of producing certain definite effects, and that certain other causes, supposed to be powerful agents, are inoperative to produce those effects, unless they are attended with the first class. All his observations are drawn from military and naval reports and personal observations, and he unquestionably deserves the credit of being the first author who has treated the subject of malaria in a strictly logical manner. In that work, which it would do Dr. Donaldson good to peruse, he distinctly limits his observations to the non-contagiousagues and remittents.

The study of these is quite distinct from that of the complaint which Dr. Donaldson found at Labuan: the two are as different as "tertian" and "typhus." I am surprised that the very practical surgeon-major of the medical staff of the Madras army did not, apparently, recognise the difference, when he saw it. In this case, I fear any arm-chair philosopher would have been more than a match for him.

The rest of the doctor's letter does not deserve notice.—I am, etc.,
THOMAS INMAN, M.D.

MEDICAL TITLES AND DEGREES.

M.D. or Physician?—"That is the question."

SIR,—In the last number of your publication, containing Sir W. Jenner's able address, I find him styled *Physician in Ordinary*, etc., also *Physician to University College Hospital*. The worthy baronet also, in his practical address, employs the word *physician* four different times, including himself once, where he states "The Presidency of the Clinical Society is, in my estimation, one of the highest honours that can be bestowed upon a *physician*." Again, Sir William adds that, "friends advise him (a patient) to consult a *physician*." The learned President then remarks, "nor would medicine as a practical science fail in public estimation, or the *physician* be less highly esteemed, were the public instructed, etc.," and as a conclusion, observes that "the *physician* in such cases is likened to the physician who, though he cannot prevent the discharge from the electric-laden clouds, can yet save," etc.

Now, sir, from the above quotations, I ask whether the above italicised repeated expressions are intended as a little joke upon some of the St. Andrew professors, teachers, or doctors of medicine, or rather to include some of those practitioners who, after a long period of general practice, have properly qualified themselves as physicians, in order that they may then combine a little more *otium cum dignitate*?

I will not weary your readers with repetitions of what has been stated upon this vexed question, but conclude by asking a simple question or two, with a view of aiding to solve it. In these liberal days, for the purpose of satisfying the majority, must we not submit, in this free land, to allow a discerning public to call or designate us what they like, or rather what they will? Can we divide ourselves in these gallant days into three classes, viz., 1. The professor, teacher, or doctor of medicine (doctor medicus); 2. The lady physician, as medicæ doctrix; and, 3. The gentleman physician, as medicus doctus?

I have here placed, or rather misplaced, the lady's position before the gentleman's. The rule in my Latin grammar says, that the masculine is more worthy than the feminine, although I cannot say from my experience that I how in this instance to the *propria que maribus auctoritas*. I leave the doctors and doctresses of music to distinguish themselves from doctors of medicine as they think best.—I remain, Sir, your humble subscriber,
Λποτέθηκα

Lincolnshire, March 29, 1875.

SIR,—A communication from Dr. Brown, of Rochester, in the last number of the JOURNAL, announces his intention of bringing before the annual meeting of the South-Eastern Branch of the British Medical Association, and his hope that similar action may be taken at the annual meetings of the other branches, the proposition, "That in the opinion of this meeting, the title of 'Doctor' ought to be accorded to all registered members of the profession, as an act of courtesy, and in agreement with general usage on the part of the public."

This question of titles has grown into importance, and has been the subject of much correspondence in the medical journals. But I hold that it is beyond any immediate or direct legal action from within the profession, and even beyond any such action on the part of the public. Titles are necessarily granted by the Crown, or obtained from such authorities as are delegated by the Crown to confer them. The title of Doctor is a university degree, the granting of which has been delegated to the respective universities under Royal Charter. If the Queen should see fit to grant such a power to any association, or college, or any official person or persons, the title conferred would of course be legal. Otherwise it cannot be legal; and if not legal, then necessarily without value. No college of physicians has been vested with the power of conferring any title beyond that of Licentiate, Member, or Fellow. The London College of Physicians has even ruled that it will not recognise any such assumption. Any other title might be as reasonably assumed without authority from the Crown. I am unable to see, if some distinction is considered to be necessary as a prefix to the name of an individual, that the old and disused custom of prefixing the word "Surgeon" should not be revived, or why those deriving their qualification from a college of physicians, should not, if they think fit, prefix the word physician. If the legal position be held to be wrong, let efforts be made by those who think so to induce "the powers that be" to extend the privilege of granting this degree; and until such extension is granted, it is surely only right that a title which is not legal should cease to be assumed. In the meantime, every registered practitioner has the same rights, and the question of relative rank or distinction is really referable to individual character, merit, and success, and may be truly said to depend as little as may be on the medical title that may have been obtained. I should be concerned to find the

short time necessarily allowed to the meetings of the Association in any degree occupied in a discussion, the outcome of which could only be a proposition to enlarge, and so far invalidate, the privileges and powers of the Universities, and which could be attended with no commensurate advantage to the members of the profession.—I am, Sir,
WILLIAM HENRY ROBERTSON, M.D., F.R.C.P.
Buxton, Derbyshire.

CORONERS' INQUESTS AND POST MORTEM EXAMINATIONS.

DR. E. HOLLAND suggests the division of all cases of death concerning which the propriety of an inquest becomes a question into three classes: a *post mortem* examination being always regarded as a necessary supplement, not only in the interests of truth and fact, but for the elucidation of mystery and the furtherance of useful pathology. The classification which he proposes is as follows.

1. Cases in which inquests are desirable and necessary.
2. Cases in which inquests are not desirable or necessary.
3. Doubtful cases, to be eventually included in one or other of the preceding classes.

As illustrations of Class 1, he selected all cases of sudden deaths directly or indirectly resulting from accident, violence, poisoning, or obvious negligence; all sudden deaths of persons away from their homes; all sudden deaths in individuals who have not been previously attended by a duly qualified and registered medical practitioner; all sudden deaths in infants out at farm, and sudden deaths from overlying; all infants found dead, whether premature or not; and all deaths (sudden or otherwise) that appear medically mysterious or tangibly suspicious; and, finally, those cases in which the survivors desire an investigation solely to clear themselves of unjust and malicious imputations.

As illustrations of Class 2, he mentions all cases of natural disease in which the patient is seen alive, but dies rapidly with the recognisable symptoms of known disease; patients suddenly succumbing in midwifery practice from hæmorrhage or embolism, in properly qualified hands; sudden deaths at their own homes or in such as are consistent with natural disease, and where there is no ground for suspicion; and, finally, all deaths from natural disease in the hands of legally qualified and registered medical practitioners.

In Class 3, he placed all sudden deaths in anaesthesia, where the anaesthetic has been administered by a duly qualified person, and in the presence of a second; all deaths under operations, or resulting therefrom, when the operation is undertaken with consent, and performed by a properly qualified surgeon, and in the presence of a second; sudden deaths from spasm of the glottis where there is a history of previous attacks; and sudden deaths from atelectasis pulmonum in infants who manifested the condition at their birth, and who, after lingering a few weeks, die suddenly without being seen by a medical man.

DR. C.—From the last annual report of the receipts and expenditure of the College of Surgeons, it appears that the former amounted to £16,596 5s. 11d., and the latter to £12,672 14s. 5d.

WE are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Croydon Chronicle; The Newcastle Daily Journal; The Derby and Chesterfield Reporter; The Hampshire Telegraph; The Newton Directory; The Hereford Times; The Hackney Express; The Liverpool Mercury; The Glasgow Herald; The Birmingham Daily Post; Saunders' News Letter; The Sheffield Daily Telegraph; The Bath Argus; The Berkshire Chronicle; The Cork Constitution; The Exeter and Plymouth Gazette; etc.

COMMUNICATIONS. LETTERS, ETC., have been received from:—

Mr. O. Lousley, Reading; Mr. R. H. Smith, Manchester; Mr. J. H. Joy, Tamworth; Rev. H. W. Waddy, Gloucester; Dr. J. Coats, Glasgow; Dr. W. T. Gairdner, Glasgow; Dr. G. H. Philipson, Newcastle-on-Tyne; Dr. Inman, Clifton; Dr. J. B. Russell, Glasgow; Dr. Taaffe, Brighton; Mr. A. Meek, Devizes; Dr. W. Handsel Griffiths, Dublin; Mr. H. J. Puckle, London; Dr. A. B. AN ADDRESS

ON THE

RELATION OF PUERPERAL FEVER TO THE
INFECTIVE DISEASES AND PYÆMIA.*Delivered before the Obstetrical Society of London, on
Wednesday, April 7th, 1875.*

BY T. SPENCER WELLS, F.R.C.S.,

Surgeon to the Samaritan Hospital, etc.

IN opening a discussion this evening on the relation of puerperal fever to the infective diseases which are among the most numerous class of cases treated by the physician and general practitioner, and to the varied forms of traumatic fever which, under the head of pyæmia, fall more frequently under the care of the operating surgeon than of the obstetrician, I wish particularly to impress upon all who honour me by their attention, that my object is rather to elicit than to impart information; to call forth the stores of knowledge now latent in the Society, to ask for the results of your observation, rather than to attempt to add to the knowledge of the Fellows by any contribution of my own.

It has been the custom of the Society in whose room we meet to stimulate the Fellows to enrich the *Transactions* by papers of original research and sterling value; to make this one of the chief objects of the Society; and, if not directly to discourage, certainly not to encourage, full or exhaustive discussions at the meetings. I have long felt, and have publicly expressed my conviction, that this course might be amended with great advantage to all medical societies, and to the advancement of medical science and practice: and I had some small share, in the earliest of the preliminary meetings of this Society—I may say even before the Society was constituted—in determining that in our *Transactions* there should be a permanent record not only of the papers read before the Society, but of the discussions to which the papers gave rise. This custom has ever since been honoured in the observance, and the example is now being followed by other societies. If I am not greatly mistaken, the discussion on Pyæmia in the seventh volume of the *Transactions* of the Clinical Society will be referred to hereafter with more interest and profit than any of the papers in that or in any of the earlier volumes of that Society's *Transactions*; and the discussion on Cancer in the twenty-fifth volume of the *Transactions* of the Pathological Society was most certainly as great an addition to the value of that volume as one could well imagine, until last night many of us heard the opening address of Dr. Bastian on a subject closely allied to some of the questions which I have to bring before you this evening, and the admirable speech of Dr. Sanderson in commencing the discussion, both full of deep thought, and eminently characteristic of the tendencies of our age and our nation to reject any theory which is not supported by facts, and to bring the highest developments of science to our help in the needs of daily life. These discussions lead to the almost painful reflection, how greatly would the value of the earlier volumes of the *Medico-Chirurgical Transactions* have been increased, if we had now not only a copy of the papers read, but a report of the comments they called forth from Baillie and Hallford; from Cline, Cooper, and Abernethy; from Travers, Brodie, and Lawrence; from Bright and Addison. The marble busts of these great men of the past now surround us; but the workers of the present and the future can find no record of what they have said here, and can only regret that, while their form and features are preserved by the sculptor, their thoughts have not been embalmed by the reporter and the printer.

"Who of us can tell
What he had been, had Cadmus never taught
To man the magic that embalms the thought?"

As I have reason to believe that the discussion this evening will be fully and accurately reported, and will be preserved in our *Transactions*, I must now ask you to pardon these few prefatory remarks, and also to forgive me if I venture to express the hope that, as the subject of puerperal fever is not of less interest than that of cancer, is closely allied with pyæmia and with the relation of bacteria to contagious and infectious diseases, it will be debated with as much ability and as complete freedom from any other than purely scientific and truthful feeling, as have characterised the discussions at the Clinical and the Pathological Societies.

If you permit me to consider what I have so far said as introductory, and to commence the subject of puerperal fever now, I hope I shall not

encroach upon your time beyond the fifteen minutes within which limit I have tried to condense what I wish to say.

In order that some definite direction might be taken in this inquiry, attention has been already publicly requested to six leading questions. The first, second, and third are so closely allied, that I will, if you please, read them together now.

1. Is there any form of continued fever, communicated by contagion or infection, and occurring in connection with childbirth, which is distinctly caused by a special morbid poison, and as definite in its progress and the local lesions associated with it as typhus or typhoid, scarlet fever, measles, or small-pox?

2. May all forms of puerperal fever be referred to attacks of some infective continued fever—as scarlet fever or measles—occurring in connection with childbirth on the one hand; or, on the other, to some form of surgical fever, or to erysipelas, caused by or associated with changes in the uterus and neighbouring parts following the process of childbirth?

3. If all cases of contagious and infectious diseases which occur under other conditions than that of childbirth are set aside, does there remain any such disease as puerperal fever?

In framing these questions, after searching for an accurate definition of the term puerperal fever, or for some short description of this as distinguished from other forms of continued fever, I have taken, as the most accurate and comprehensive, the definition from the Nomenclature of Diseases drawn up by a Committee appointed by the London College of Physicians (for which definition I believe the Committee are indebted to Dr. Arthur Farre). It is this: "A continued fever, communicable by contagion, occurring in connection with childbirth, and often associated with extensive local lesions, especially of the uterine system." To this definition, this very important note is added: "In returning cases of puerperal fever, the more important local lesions, such as peritonitis, effusions into serous and synovial cavities, phlebitis, and diffuse suppuration, should be specified."

Here, then, we are led, on the authority of the most distinguished obstetric teacher of his day, supported by a committee appointed by the Royal College of Physicians of London, to the conclusion that in puerperal fever we have a contagious continued fever often associated with the important local lesions just enumerated; not always, but often. You may then, according to this definition, have this contagious fever without these local lesions. The poison may be so potent, or the dose so large, that it may kill before there is time for the development of the local lesion; or the dose may be so small, or the poison so feeble, that it only produces some transient elevation of temperature, some greater rate in pulse and respiration, some increased action of skin, kidneys, and bowels, and the morbid material is eliminated before any local lesion is established. But I must ask you to say if, in your experience, you ever saw such a case which could not, on careful inquiry, be traced to exposure of the patient to some one or other of the contagious or infectious fevers—to scarlet fever or diphtheria—to measles or small-pox? I need not remind you how these diseases are intensified or modified by the puerperal condition; and I proceed to ask if, in any case where puerperal fever could not be proved to be really scarlet fever, diphtheria, measles, or small-pox occurring in connection with childbirth, it was not a traumatic or surgical fever, erysipelas, pyæmia, or septicæmia; the local lesions associated with the fever assuming rather a primary than a secondary importance in the chain of sequence. Time does not permit me to enter on the very important practical question as to the sole dependence of erysipelas upon a specific morbid poison. Whether this peculiar inflammation of the skin and cellular tissue, tending to spread indefinitely and preceded or accompanied by fever, can arise from the spontaneous generation in the human body of a poison communicable by contagion; or, whether a poison capable of producing erysipelas exists at all times in varying quantity somewhere, ready to increase and multiply under favourable conditions; or, whether (as some believe) erysipelas may arise independently of any poisonous influence from without, we need not inquire now. The important fact for us now is, that erysipelas often attacks the parts concerned in the process of childbirth, and that the fever which accompanies it, intensified by the puerperal condition, is a very fatal form of one of the diseases confounded together under the term puerperal fever. Set aside the infectious fevers and erysipelas occurring in connection with childbirth; and then we come to the local lesions associated with puerperal fever, and we ask what relations this fever and the local lesions bear to each other. Bruises or tears of the genital canal or perineum; inflammation, and the production of pyrogenic liquids or solids, which may contain both bacteria and some poisonous material or particles which have the power of impregnation; diphtheritic exudation on the mucous membrane of the uterus and vagina, especially on the place of the separated placenta, and plugging of the lymphatic vessels with granular

masses or colonies of bacteria or spheroids; the rapid development and growth of plant-life, and the disturbance of function and alteration of structure which must follow; does all this arise under perfect sanitary conditions, spontaneously, or from mere chemical decomposition, or only when some poisonous agent is introduced from without—the seed of some plant sown in a fruitful soil?

Again, supposing inflammation is set up in the uterus, in its veins and lymphatics; that the albuminoid secretion known as the lochial discharge contains pus; that pus, or putrid material, or organic germs, are found in the lymphatic vessels of the uterus and the subperitoneal cellular tissue, with diffuse peritonitis; that the blood in the uterine veins clots, softens, breaks up, is the seat of chemical and vital change, is detained in or near the pelvis, or is carried away to distant parts, or alters the composition and properties of all the blood in the body; that we have purulent infection, or pyæmia—putrid infection, or septicæmia; can all this arise in a healthy woman, placed in favourable conditions, if she be not exposed to some morbid poison? Is puerperal fever ever a simple traumatic fever modified by this puerperal condition, or does it always and necessarily depend on the action of a morbid poison? Or, let me put the question in another form. Did you ever see a case of puerperal fever which was not really either a case of scarlet fever or measles, or some such infectious or contagious fever, or erysipelas? or a traumatic fever caused by the bruising or tearing of the parts concerned in childbirth, and the changes in the blood-vessels, blood, and lymphatics, following the injury? If you have seen such a case, then let us know something about the fever, its period of latency, its course and duration, and its termination; and especially tell us something about the poison which has been the cause of the fever.

Time does not allow me to do more than put the question. I await your reply, and pass on to the fourth, fifth, and sixth heads of our subject, which I will also read together. They are these.

4. Assuming that a form of continued fever—communicable by inoculation, contagion, or infection—does frequently occur in connection with childbirth, how can its spread in private and in hospital practice be most certainly prevented or checked?

5. What relation have bacteria and allied organic forms to the pyæmic process in the puerperal state?

6. What is the value of antiseptics in the prevention and treatment of puerperal fever?

And, to show the close connection of these with the previous questions, I must remind you that even those who admit that a tear of the perinaeum, or a bruise of the vulva, by leading to inflammatory exudations around the vagina or uterus, or to clotting of blood in the veins, and consequent changes in the whole of the blood in the body, is quite sufficient to account for fever, which, aggravated by the puerperal condition, may lead to all the local lesions specified in the note to the official definition of puerperal fever—even those believers in the spontaneous or local origin of the fever, seeing the hundreds of cases where the injury is observed without the fever for every one where the fever is observed, and the prevalence of the fever in certain seasons and districts, and in the practice of certain surgeons or midwives,—still freely admit that it is only under some endemic or epidemic condition, or as a result of contagion or infection, that the ordinary wounds, or bruises, or tears, inevitable during the process of parturition, and commonly free from any serious consequence, become in exceptional cases so deadly.

It is especially in this direction that the knowledge of our country Fellows may be of the greatest value to us. In the practice of a large hospital, or in private practice in a large city or a thickly populated district, it is impossible to say that a patient may not have been exposed to some contagious or infectious disease. But, when isolated cases arise in private practice in the country, where any source of poisoning can be readily traced, the accurate record of such cases, their origin and course, and their arrest or extension, may be of incalculable value. A country surgeon attends a man who has erysipelas after a broken arm. He also attends a healthy woman in an isolated cottage in a natural labour. There is no puerperal fever in the district, yet this woman dies of puerperal fever, and so do others attended about the same time by the same surgeon. These women, in all probability, would have recovered in the ordinary course, had not erysipelas occurred in the man who broke his arm. Such a history as this would have tenfold weight, as being free from numerous sources of fallacy and doubt attending any similar history in a large city.

And, again, we cannot consider the mode of preventing the spread of puerperal fever without examining into the part which bacteria and other organic forms may play either as poisons or as carriers of poison. Here I must ask you to allow me to refer to a paper, which I read twelve years ago at Cambridge, on the Causes of Excessive Mortality after Surgical Operations. It may be found in the second volume of

the *Medical Times and Gazette* for 1864. In that paper, I gave some account of Pasteur's researches on fermentation, on the organised corpuscles in the air, on spontaneous generation, and on putrefaction; sketching rapidly the results of some of his researches, to show the influence of the germs of the lowest organisms present in the atmosphere, especially bacteria and vibrios, upon animal bodies in health and disease, and on our tissues during life and after death, and especially upon the development of epidemic and contagious diseases. I also showed, from the observations of Angus Smith, Chalvet, Eiselt, and Réveil, that germs may be often found in the air of crowded rooms and hospital-wards, which only require favourable conditions for their rapid development.

Now that the influence of bacteria is beginning to assume a more general importance in pathological investigation, I must remind you of the account, which was published twelve years ago, of what I even then thought Pasteur's discoveries were leading us to. I may also say that, in the same paper, I gave some account of the relation of bacteria to splenic apoplexy in sheep; and referred to demonstrations of the presence of living germs in the air capable of reproducing contagious diseases, by Lemaire finding the acbörion in the air which had passed over a scalp affected with favus, and by the experiments of Kennedy and Salisbury on the production of measles by the inoculation or inhalation of fungi given off from mouldy straw or linseed-meal. And then, in concluding that paper, after recording proofs—1. That the injection of a certain quantity of pus into the blood produces pyæmia and affections characterised by multiple abscesses; 2. That the injection of putrid matter produces septicæmia, or putrid infection, characterised by the symptoms of typhoid gastro-enteritis; 3. That the injection into the blood of the exudative materials in contagious diseases, as in glanders, produces the general contagious affections; and that, in all these cases, the introduction of the foreign substance or poison into the blood must be regarded as the origin of the disease—I went on to give some account of Polli's antiseptic treatment of these various forms of disease by sulphurous acid and the alkaline and earthy sulphites, showing how they arrest or prevent fermentation and putrefaction, and how it might not only be expected that the living fluids and tissues charged with the sulphites would resist the action of morbid poisons, and that there were proofs that, when the sulphites had been taken, they really altered the actions of pus upon the blood of a living animal, as well as that of putrid matters injected into the blood, and that of a virus distinctly contagious and not putrid.

This was in 1864. It was two years afterwards—towards the end of 1866—that Lister began to treat cases antiseptically in the Glasgow Infirmary, using carbolic acid rather than sulphurous acid or the sulphites but with the express purpose of destroying the organic germs present in the air, or in any of the liquids or solid substances about the patient; or of protecting any wounded or injured part from the contact or development of the germs. Now he has gone on gradually perfecting the details of the antiseptic system, I need not describe to you; and the results are too well known to require more than the most passing allusion to the prevention of surgical fever, of pyæmia and septicæmia, the checking the spread of erysipelas after its importation into a ward, the lessening of mortality after both the greater and the more trifling operations, the saving of limbs after compound fractures, the healing of large burns, ulcers, or abscesses, and the general freedom of hospital-wards from noxious odours and matters, and from the introduction of poison from the dead-house or dissecting-room, while the hospital atmosphere is not only purified for the patients, but for the surgeons and nurses.

If all this have been gained since 1866 in Glasgow and Edinburgh, and in other British and foreign hospitals, where the example has been more or less closely followed; if traumatic fever and pyæmia can be kept out of a surgical hospital, why should not puerperal fever be kept out of a lying-in hospital, or be prevented from spreading, if it have been accidentally imported? There has been a great outcry against lying-in hospitals of late; but I trust this Society may be able to guide the feeling rather in the direction of freeing them from puerperal fever than of destroying them. What has been done by reducing the size of a surgical hospital in Edinburgh and in London, the size of the wards, the number of beds in each ward, the number of attendants, and enforcing the utmost care in protecting the patient from any contagious or infectious influence, and in securing the greatest possible cleanliness in all things about her; in reducing the mortality after one of the most serious operations to which a human body can be subjected and still live,—is known to those who have watched the progress of ovariotomy. It is for you to say whether a similar enforcement of obedience to the laws of sanitary science, a more exact observation of the origin and progress of the many different conditions which have been classed together under the one head puerperal fever, and of the treatment called for by each condition; and a

careful attention to the details of the antiseptic system, as it is brought more completely into accord with our daily increasing knowledge of the natural history of the lowest forms of organic life, shall or shall not be your rule and guide henceforth in your daily practice. What I have said in the very hasty and imperfect sketch it has been possible for me to offer in the few minutes you have so kindly accorded to me may soon pass out of your thoughts. But I am fully persuaded that there are many here to-night who will be able to assure us that such a diminution of unnecessary or excessive mortality after childbirth may be hoped for as may relieve you and your successors from much anxiety and sorrow, and, while making your own lives more useful and happy, may raise still higher in national esteem the noble profession to which we should all be proud to belong.

TWO CASES OF INOCULATION WITH THE SEPTIC LOCHIA OF PUERPERAL WOMEN.

By WILLIAM STEWART, L.R.C.P. Edin., Barnsley.

THE elucidation of the nature of the poison and the etiology of puerperal septicæmia, is of such vital importance, and, at the present time, occupies such a prominent place in the mind of the profession, that I feel no apology is required from me for bringing under the notice of the profession the two following cases.

CASE I. Miss G., aged 52, a delicate woman, frequently suffering from hepatic derangement, and the subject of an obscure internal abdominal tumour, said to have followed an injury from a railway accident, called me to see her on Sunday, October 8th, 1871. I found her suffering from most excruciating pain in the right forefinger. The pain was so agonising that I was led to inquire whether she had not scratched or injured it in any manner, when she informed me she had very slightly scratched that finger and the one next to it a few days previously. Upon remarking further that I was afraid she had received some poisonous matter into the scratch, she then remembered having given an injection to a lying-in woman on the evening of the 6th (about thirty-six hours before my visit), whose nurse was very inexperienced, and had neglected to change the patient for several days after delivery. I was informed by the medical gentleman in attendance upon the confinement, that his patient had peritonitis at the time. My patient had wrapped a piece of adhesive plaster round the middle finger, which was therefore quite unaffected, but unfortunately had left the scratch on the forefinger totally unprotected. Here, then, was the clue to the case, decomposing lochial discharge applied to the recent scratch. This case ran a most acute and rapid course. Thirty-six hours after the application of the septic matter, I saw the patient. The finger was then hard and indurated, but not much swollen. The back of the hand was very red and much enlarged. The inflamed lymphatics in red streaks could be seen passing up the forearm; and in twelve hours more, in spite of all measures adopted to arrest the advancing disease, the finger had mortified. The next day, her relatives being very anxious, I met in consultation two neighbouring medical gentlemen, who agreed with me as to the cause of her symptoms; but the gangrene continuing to spread soon involved the other fingers, hand and wrist, and was followed by a fatal termination on the 10th, being ninety hours from the application of the poison, and about forty-eight hours from the time when I first saw the case. Throughout the short course of her illness, the general symptoms were those of high fever, persistent vomiting, and, towards the close, delirium.

CASE II. The poison in this case was introduced from a puerperal patient in my own practice. Mrs. L., a primipara, was delivered by Dr. Heath, my assistant, on October 24th, 1874. Three days afterwards, symptoms of acute peritonitis set in, preceded by decomposition of the lochia and accompanied by profuse diarrhoea, and other symptoms of blood-poisoning. Injections of Condy's fluid into the uterus and vagina were used to disinfect the discharge. These were administered by Mrs. M. (her mother), who, on November 5th, two days before her daughter's death, had inflicted a slight wound with a table-knife over the first joint of her left thumb. The wound being slight, she did not consider it necessary to mention it, or to apply any dressing to the part, but continued to administer the injections without any protection to the thumb. On the 7th, I found her suffering from most violent pain in the thumb, which was swollen and indurated; the wound was gaping and sloughy in appearance, the back of the hand red, shining, and erysipelatous. A free incision on the thumb above the wound, followed in a few days by another on the back of the hand, gave exit to a large quantity of pus, and relieved to a certain extent the severity of the symptoms; but the purulent affection seemed to travel along the cellular tissue of the forearm, which in turn had to be relieved by inci-

sion. The lymphatics were inflamed as high as the elbow, where there was a patch of erysipelas. This case terminated favourably in six weeks, leaving only the first joint of the thumb stiff.

These cases appear to me to be specially instructive; first, because of the danger to which attendants are exposed when it becomes necessary to give vaginal injections to puerperal patients. And I think it becomes the duty of the medical attendant to warn the nurses to take precautions not to allow the discharge to come into contact with any recent wound or abrasion of skin. Secondly, they are exceedingly interesting from their tendency to throw light upon the nature and production of puerperal septicæmia, as they show that the application of decomposing lochia alone to a recent scratch or wound has been sufficient of itself to produce gangrene of the part and death of the patient in the one case, and a very severe attack of phlegmonous erysipelas in the other, although no puerperal condition existed in either of the inoculated subjects. I think we may, therefore, draw the conclusion, that the passage of decomposing lochia over any abraded surface in the vaginal passage is sufficient to produce puerperal septicæmia without the importation of any other specific poison. In this manner, we may account for the disease attacking much more frequently primiparous cases, as the vagina and perineum are much more likely to be slightly lacerated in those than in multiparæ. If it were possible to apply as effectually the antiseptic treatment to these cases as it is carried out by Professor Lister in surgical cases, I have little doubt that as good results would be obtained. Obstetricians too frequently begin to lock the door when the horse is stolen; we wait until there is evidence of decomposition having already taken place in the lochia before steps are taken to prevent or counteract the danger. Cannot some antiseptic means be devised to be used from the time of delivery? I should be inclined to think that folds of antiseptic gauze instead of the ordinary napkin, and an antiseptic lotion for detergent purposes, would be of very great service, and might prove quite sufficient to prevent the setting in of putrefactive change in the discharge.

ERYSIPELAS AND MIDWIFERY PRACTICE.

By HENRY H. HATHIERLEY, M.R.C.S. Eng., Nottingham.

THE following case is, I think, of especial interest at the present moment, when the question of infection in relation to midwifery practice is much discussed.

Mrs. H., aged 37, wife of a lacemaker residing in New Radford, came under my care on January 8th last for erysipelas of the face, she being at the time far advanced in her tenth pregnancy. The course of the disease was at first most unfavourable, the whole of the scalp and naso-pharyngeal tract becoming involved. She had great fever and prostration, sleeplessness and constant delirium, and marked difficulty of deglutition. On January 11th, she was confined by a midwife of a live male child at the full term. From January 11th, Mrs. H. steadily improved; the erysipelas subsided; the lochia were profuse, but otherwise natural; the secretion of milk was normal. Both mother and child (who still has the breast) did well.

In this case, parturition, instead of adding an element of danger, appeared to have a favourable influence on the course of the erysipelas, the patient's improvement dating from her confinement. The midwife has an extensive practice, but no harm accrued to any of her patients. I attended about this time nine labours (between January 5th and 22nd), all of which did well, although I took no special precautions to prevent infection.

I think that, as far as any inference can be drawn from this isolated case, it is that the danger of infection to lying-in women from ordinary zymotic disease is less than is commonly supposed, and that a medical man is justified in fulfilling his midwifery engagements when attending infectious cases other than true puerperal fever.

The question of responsibility for infection is a very serious and a very difficult one; to debar practitioners (morally, if not legally) from attending midwifery, whilst attending cases of scarlet fever, erysipelas, typhoid or typhus fever, diphtheria, etc., would not only mean ruin to many a medical man, but would so limit the number of medical men "justified in practising" as seriously to inconvenience the public.

I am one of those who believe that the term "puerperal fever" is applied too comprehensively, and that a more strict definition of this disease would shut out many so-called cases of "puerperal fever". I would ask, in conclusion, the following questions.—1. What proof have we that puerperal fever is not a distinct zymotic poison, incapable of being produced by any common infectious disease? 2. Can it be proved by statistics that puerperal fever is generally of more frequent occurrence during the prevalence of such diseases as scarlet fever, erysipelas, etc.?

NOTES OF A SHORT ADDRESS TO THE CANDIDATES AT THE OPENING OF THE ARMY MEDICAL SCHOOL AT NETLEY, APRIL 1ST, 1875.

By J. FAYRER, M.D., C.S.I.,

President of the Indian Medical Board; Member of the Senate.

GENTLEMEN,—By permission of Dr. Fraser and the Senate, I propose to make a few remarks on this occasion of the commencement of another session of the Army Medical School. My reason for doing so is, that I think a few words from one who has been long engaged in the work you are commencing may not be out of place. They will be the result of some experience, and you may accept them as a token of the interest I take in your future career.

No position in which I have been placed has afforded me more satisfaction than that I now occupy as a member of the Senate of this School; for it places me in relation with the rising generation of medical officers, and enables me to feel that I may still in some degree further that which has always deeply interested me—medical education.

It is more than a quarter of a century, though it seems but as yesterday, since I was, as you now are, commencing my career as a medical officer; but how great are your advantages, compared with those of the date to which I look back! How much has been done to promote your interests and improve the means of fitting you for your work! Since the Crimean war, great changes have taken place in the constitution of the medical services, and in the duties and responsibilities of the medical officers. The sciences of military hygiene and medicine have made rapid progress. The medical officer is no longer regarded merely as the physician or surgeon to treat disease or wound; he is the guardian of the health of armies and fleets. In some cases, and especially in India, he holds the same position in regard to the civil population. It is a fact, that officers in the Indian Medical Service, as sanitary commissioners, are the guardians of the health of two hundred millions of people.

Your duties will be of a varied character, and you must be well prepared to discharge them efficiently. Prevention of disease and preservation of health are very essential; but they must not occupy your attention to the exclusion of the study of disease itself, which you must be prepared to treat in every form, and as it occurs in epidemic and endemic visitations. You must be general practitioners in the widest sense of the term, equally prepared to perform a surgical operation, treat disease, lay down the sanitary conditions for the proper construction of a barrack or hospital, analyse a doubtful potable water, detect an obscure poison, or deal with an impending or present visitation of cholera or other epidemic disease. Where you are going, there will be no room for specialisation. Admirable as the specialist may be in great cities, he would be of little use in a field-hospital or ironclad during an action, or in a cholera or fever camp in India or the tropics.

In some services, the medical officers have substantive military rank. The Medical Director-General of the United States army is a general. The reports of his department contain papers by majors and captains, who are the surgeons and assistant-surgeons of regiments. Such is not the case with us; and you must bear in mind that, though your position is as good as that of other officers, your relative rank gives you no title to assume the duties or offices of the combatant branch. I need hardly hint at the bad taste of assuming anything to which you are not entitled, especially that to which your own position as members of a learned profession should make you indifferent. But still you are soldiers; and it may happen, as it has done before, to devolve on you, in emergencies, to act as such. You have many brilliant examples of the medical taking the place of the combatant officer. Should it fall to your lot, be ready to show that you are as ready for this as for any other duty.

Let me advise you not to forget that you are medical at the same time as you are military men. Let there be a due combination of each element. Keep to your own distinct sphere of duty, and you will exercise great influence for good. Overstep it, and you will not only be in a false position, but your efforts for good will be negated, and your counsels useless. So much of the influence for good in the position of the medical officer depends on his personal character, that you should endeavour to let the standard of that be pitched as high as possible.

Whatever may be said or thought of the position of the medical officers collectively, no one can deny that individually they always receive the consideration and respect that is due to their own individual and personal merits. You have abundant examples—living, I am glad to say—to imitate; and I might remind you of one recently removed from among us ripe in age and distinction, who always and to the last took deep interest in this school and in his younger brethren, who

has left us the history of a life and character, which all young naval and military surgeons may study with advantage.

Having completed your work at Netley, you will be ready to enter on your duties, and you will probably think that you are entitled to rest after your labours, and have leisure to digest and assimilate all that you have taken in here. But short interval will intervene before you are in harness, and begin the business of life in earnest. You will realise the value of the training you have received. You must act for yourselves, add to your stock of knowledge and that which may be of use to your successors in this school, when, perchance, one of you may occupy one of its professorial chairs, or endeavour, as I do, to encourage your younger brethren in starting on their journey in life.

The field before you is large. Far from being exhausted, it is in many places hardly touched. Great problems of hygiene and medicine still await solution. Large questions concerning disease; the laws regulating the rise and spread of cholera and other epidemics, their pathology, etiology, and therapeutics; the nature and action of that which in our ignorance we call malaria; the subject of fever in all forms; and many kindred subjects—will engage your attention, and give you ample ground for exploration and discovery. Or, apart from medicine and hygiene, we may turn to the whole range of natural science. The zoology, botany, geology, mineralogy, meteorology, climatology, ethnology, of many countries, and especially of India, offer rich mines, in which are veins of wealth yet unexplored and unrevealed.

You must feel a longing to enter on a career that offers so many paths to instruction. Think, too, of the examples in whose footsteps you may follow, and of what has been done by such men—all military or naval surgeons—as Guthrie, Ballingall, Richardson, Falconer, Annesley, Twining, Thompson, Martin, Hooker, Huxley, Flower, Parkes, Maclean, Longmore, Goodeve, Chevers, Murchison, and many more; and shall they not be followed by some whose names will be written in the annals of this school? I must not dwell longer, much as I should like to do so, on this subject, for I have a few words to say about the services you are to join, and especially of the Indian; for though I have served in them all, I am best qualified to speak of that in which the greater part of my life has been passed.

The covenanted Indian medical service comprised, on January 1st, 1875, 675 members of all ranks; of these, 3 were surgeons-general, 22 deputy surgeons-general, 357 surgeons-major, and 293 surgeons. The designation of assistant-surgeon, as you are aware, has been discontinued. This was a title in no case, perhaps, very appropriate, but least of all so in India, where most commissioned medical officers held independent charges from the beginning. There are three divisions, those of Bengal, Madras, and Bombay, each with its own list, and not concerned with the others. To one or other of these, according to circumstances, already doubtless known to you, those destined for India will belong; and to any of the varied appointments offered by them each of you may aspire. I wish, however, to remind you, that the Indian medical service is not purely military, but general, and that it is not the public medical service only, but the medical profession in India; for on you will devolve all important professional duties, including medical education, in the country.

Two years must be passed in military duty before you can obtain promotion; but, after that is completed, the work is often of a different character, and quite distinct from the army. There is also another condition, that, before you can permanently hold any appointment, civil or military, you must pass an examination in the language of the Presidency to which you belong. This used formerly to be merely colloquial; it now includes both reading and writing the language in the native character, and I strongly recommend you to set yourselves to do this immediately after reaching India. It is important that you should commence it early, for if put off it becomes irksome, as increasing work leaves you less time and inclination to devote to it. Though the lower standard, as it is called, is all that is absolutely required, you will do well to aim at the higher; and there are others still more advanced, for which a successful examination is rewarded by a considerable sum of money—sufficient, at least, to defray the expenses of tuition. The value of a sound knowledge of the language is great; it is seldom acquired if not begun early; it is essential in your communication with the natives, and is a condition of holding many appointments. No one, I am sure, has ever had cause, even when it was not compulsory, to regret the time or labour bestowed on it.

The grades in the Indian are like those in the British medical service, though you have the exceptional advantage of promotion to surgeon-major after the lapse of twelve years, if you have passed a professional examination, which is, in future, to be enforced, though it has not been so up to the present time. This, also, you should do as soon as possible, whilst the habits of study and passing examinations, in which you have been pretty well exercised, are fresh upon you. De-

pend on it, these things do not become easier from delay, and you will feel more comfortable and settled in your real work, with minds relieved of the burden.

After twenty years' service, you will obtain a step in relative rank and an increase of pay. After this, should you remain in the service so long, comes the next step of deputy surgeon-general. A period of five years in this grade adds materially to your pension (£250 a year). Should you be fortunate enough to attain the highest post of all, that of surgeon-general, and hold it for five years, your pension will receive another substantial increment of £350. But, though few may attain to this position, there are many other appointments even more lucrative, though not involving extra-pension, some connected with the military service, others quite distinct from it. The appointments open to medical officers are fewer than formerly; still they are numerous, and I will tell you briefly what they are, or have been, since my own connection with the service.

In addition to the administrative appointments of surgeon and deputy surgeon-general, the following are now, or recently were, held by medical officers; principal and professors in all the subjects of an university curriculum in medicine, in the Colleges of Calcutta, Madras, Bombay, and also a limited number in the College of Lahore; superintendent of native medical schools at Agra, Nagpore, Patna, Dacca, etc.; these generally being held in combination with the office of civil surgeon of these important stations.

The important subject of medical education will be entirely in your hands, whether as members of the medical faculty, of the senate, or as examiners in the Universities of Calcutta, Madras, or Bombay, or as professors in the Medical Colleges. The new College of Calcutta, which was founded in 1833 by Lord W. Bentinck, is, I may tell you, the largest medical school in the world. When I left it in 1872 it numbered over 1,300 medical students on its rolls, and it is increasing every year. There is, perhaps, nothing that has exercised a greater political or social influence for good on the native mind, or done more to consolidate our hold on the affections of the people and the country, since the days when Broughton and Hamilton gained for the British power the earliest concession of privileges which gave us our first hold in the country from the Moghul of Delhi; and since when, in 1836, the learned Pundit Moodhosoodun Guptoo, laying aside the prejudices of caste, initiated the study of anatomy by dissecting the human body, than the study and extension of medical science in India. It will be for you to sustain and extend the prestige it has acquired, and there is, perhaps, no direction in which your talents and energies may be more usefully directed.

Among offices that may be, or have been, held by medical men in India, the following may be mentioned:—

Surgeons and assistant surgeons, and resident surgeons of the General and College Hospitals; superintendents of eye infirmaries; garrison surgeons; field surgeons and assistants to armies in the field; surgeon to the viceroy; surgeon to the commander-in-chief; presidency and district surgeons; marine surgeons; police surgeons; superintendent of lunatic asylums; superintendent of emigration; medical superintendent of emigration; medical examiner of accounts; principal medical storekeeper; other medical storekeepers; civil surgeons of stations, very numerous; and sometimes remunerative appointments, to which are joined others; regimental appointments; chemical examiners to Government; analysers of waters; assay and assistant assay masters; superintendent of botanic gardens, Calcutta, Scharunpore, and others; of cinchona plantations; forest appointments; superintendent of fisheries; sanitary commissioner to Government of India; sanitary commissioner of provinces; statistical officer and officers on special duty for investigation of cholera, held by two very distinguished students of this school, Messrs. Cunningham and Lewis; inspector-general and inspector of jails; superintendents of jails; inspector-general and superintendents of vaccination; political agents; assistant political agents; magistrates, coroners; commissioners and deputy commissioners of divisions, offices involving judicial functions; opium agents and assistants; professor of Arabic and secretary to Colleges (formerly); governor of the Andaman Islands (formerly); superintendent of Darjeeling, the late lamented Dr. Campbell; a former Persian envoy; and others that at this moment escape my memory. With many of these offices are combined other duties, or two or more may be held by the same officer.

In most cases, the civil and military medical appointments give opportunity for private practice. In the Presidency cities and larger civil stations, it is often considerable; and though, perhaps, not so lucrative anywhere as in former days, it is such as would compare not unfavourably with the results of medical practice in European cities. I have heard it said, that the late Dr. N., when surgeon to the General Hospital in Calcutta about thirty years ago, made as much as one lac of rupees, £10,000, a year. Things have changed since then;

medical men are more numerous and honoraria are smaller. Those who realise half the amount are fortunate; but this is not equal to the same in England. The cost of living is great, and the expenditure large; but if health continue, most medical officers may look forward at the completion of their service to retirement with a competency. Unfortunately, health is not always preserved, and the position is forfeited by the necessity of seeking change in Europe. But, lest I should excite undue apprehension in reference to the evils of the climate, I will presently say a few words on the mode of life in India.

I have thus given you a glance at your future work, and an idea of what you may aspire to: I am sure it depends on yourselves how far you may profit by the advantages offered. In these days, though interest and the influence of friends will do something, they are as nothing to personal merit, which will do more.

To men of apathetic temperament, though correct in all their proceedings and relations of life and duty, the opportunities may seem never to come; but the real fact is, they are neither perceived, nor grasped when they offer, and the favourable moment passes by unheeded, perhaps not to return, and mediocrity is the result; but even to these the service offers something. There is sufficient for all present wants and a pension for the future. After periods of from seventeen to thirty years, you have the option of retiring on a pension according to the length of service, varying from £220 to £550 a year, or if the last five years have been passed in the position of deputy-surgeon or surgeon-general, you will add an additional £250 or £350 to your pension. A liberal allowance of leave is accorded, amounting to six years in the whole period of thirty years; but, unless under very exceptional circumstances, not more than two years can be taken at a time, and that after stated intervals. You will do well to avail yourself of this privilege, even though your health should not seem to require it, for it gives you the opportunity of renewing your home impressions, and refreshing your knowledge of professional subjects; and you will do very well, if it be permitted, to spend portions of your furlough here with that object.

Now, as to your mode of life in India, and indeed other hot and tropical countries, with reference to the preservation of health, I have not much more to say than that common sense and careful living are all that are required. India means every variety of climate, from the hot damp plains of Bengal to the dry arid plains of the north-west and Punjab, or the cold rarefied atmosphere of the Hill stations; and you must act accordingly. Temperance in all things; regularity of life and habits; avoidance of excessive, prolonged, or undue exposure to the direct rays of the sun and to malarious influences, especially as they occur in certain localities; attention to clothing, which should consist mainly of light woollen materials, to protect you from chills, and equalise the temperature of the body; plenty of, but not too much, work; sufficient exercise; plain food, and extreme moderation in alcoholic drinks of all kinds; and as little tobacco-smoking as possible—these precautions, if observed, will keep you in good health, and fit for work for many years; and you will find, I think, as a general rule, that men in India work as hard or as harder than they do here, for, from the time you occupy a position of the least responsibility, work goes on steadily increasing, and developing new motives to exertion.

Of course, in such climates as those of India and the tropics, one is liable to sudden and serious attacks of disease; but, escaping these, as you may reasonably, with care, expect to do, it is wonderful how high a standard of health may be preserved even under the hardest work and the greatest exposure. The tendency is to suffer as much from mental as from physical strain, and as many break down from overwrought brains as from physical exhaustion; but, fortified by such means as I have suggested, you may to a great extent bid defiance to both. I would repeat the advice that you should, if possible, avail yourselves, at reasonable periods, of the leave which the Government accords you to Europe. It is often said that the doctors and the indigo-planters, men who are most exposed, are the healthiest men in India. This is not, perhaps, altogether true; but it shows that the advantages of exercise, combined with mental occupation, are popularly recognised.

And now a few words to those of you who are destined for the Navy and Army. Though I cannot profess to indicate all that you may look forward to so well as I can to your Indian colleagues, yet this much I may safely assert, that for you, too, an interesting field of work is open; and, though the variety may be less than in the Indian service, yet it is equally interesting and important. To you will be committed the care of the health of our soldiers and sailors, and of our military and naval stations at home and abroad. Many of you will work side by side with your Indian friends. In the event of war—and who can say how long we shall remain at peace?—the treatment of our sick and wounded will also be your care. To you also it will fall to investigate the laws that

govern the origin and diffusion of epidemic and other forms of disease; and, as your experience will be gathered in all quarters of the globe, your opportunities of studying the influences of climate will necessarily exceed those of all others, and will enable you to solve problems that are yet unexplained. Nor will your duties be limited to those of a purely military or naval character; for, though I am not sufficiently acquainted with all the details of your services to describe them, I know that there are many special appointments open to those who will aspire to them. In short, to whichever branch of the service you belong, you have before you an useful and honourable career, which will be useful and honourable just in proportion to your own application of the capabilities you possess. In no case, I fear, may you expect to acquire wealth. Were this your object, you should have chosen another profession; but competency, and the means of doing justice to your families, and of supporting the position you attain, you may realise; and if so, and you feel that you have served your country well, and to the best of your ability advanced the knowledge of your profession and the bounds of science, you may be content, for you will have gained that which will bring you the truest happiness and the best reward.

And now I must not detain you longer. I have already trespassed too much on the patience of all, and I will conclude by wishing you all prosperity and success in your present and future career.

ON THE ACTIONS OF PICROTOXINE, AND THE ANTAGONISM BETWEEN PICROTOXINE AND CHLORAL HYDRATE.

By J. CRICHTON BROWNE, M.D., F.R.S.E.,
Medical Director of the West Riding Asylum.

(Continued from page 478.)

HAVING clearly established the existence of a remarkable antagonism between picrotoxine and chloral-hydrate, I next performed a few experiments with the purpose of supplying an answer to the important practical question, how long after the administration of a fatal dose of the one, may the other be administered with any hope of saving life.

TABLE VI.—Showing the Influence of Hydrate of Chloral Injected at Different Intervals of Time after Picrotoxine.

No.	Weight of Guinea-Pig.	Dose of Picrotoxine in parts of a grain.	Dose of Chloral in grain.	Interval between administration of Picrotoxine & Chloral Hydrate.	Effect.	Result.
47	1 lb. 9 oz.	1-20th	6	10 min.	Deep sleep, twitches	Recovery
48	1 lb. 8 oz.	1-20th	7	15 "	Restlessness, staggering, startings, convulsions, deep sleep	"
49	1 lb. 10 oz.	1-20th	7	30 "	Restlessness, twitches, convulsions, sleep	"
50	1 lb. 9 oz.	1-20th	7	34 "	Restlessness, violent convulsions, coma	Death in 5 hrs.
51	1 lb. 6 oz.	1-20th	6	40 "	Restlessness, convulsions long continued	Death in 2 hrs.

It thus became evident that chloral-hydrate as an antidote to picrotoxine may be effectually employed for half an-hour after the reception of that poison into the system, and even after several severe convulsive seizures. The certainty and celerity with which alleviation followed the introduction of the chloral into the system in the experiments above tabulated, as well as in a rabbit, to which twenty grains were given twenty minutes after a sixteenth of a grain of picrotoxine, which had induced four violent fits, was most striking and satisfactory. It may be safely asserted that if, after a poisonous dose of picrotoxine, chloral can be given in proportionate amount before the occurrence of clonic spasms, life will certainly be saved; and that, if it be given even after several convulsive seizures, but before the spasms have become continuous, there is still a good prospect of a favourable issue.

The next point which it was thought requisite to determine was, whether the antagonism between chloral-hydrate and picrotoxine was interchangeable. Could the lethal action of chloral be as certainly arrested and modified by picrotoxine as that of picrotoxine had been shown to be by chloral-hydrate? In proceeding to solve this problem, advantage was taken of the researches of the Edinburgh Committee to avoid a tedious preparatory inquiry. The report of that Committee

had approximately fixed the minimum fatal dose of chloral as twenty-one grains for a rabbit of three pounds weight, or seven grains for each pound of body-weight. That result being accepted as accurate, the following experiments were instituted.

TABLE VII.—Showing the Effects of Picrotoxine when injected with Fatal Doses of Chloral-Hydrate.

No.	Weight of Rabbit.	Dose of Chloral-Hydrate in grains.	Dose of Picrotoxine in parts of a grain.	Effects.	Result.
52	3 lbs. 4 oz.	23	1-40th	Prostration, sleep slightly disturbed	Recovery
53	3 lbs. 9 oz.	25	1-20th	Deep sleep, from which readily roused	"
54	3 lbs. 7½ oz.	30	1-25th	Restlessness, sleep much disturbed	"
55	3 lbs. 1 oz.	30	1-20th	Lethargy, loss of power in hind legs, deep sleep	Death in 4 hrs.
56	2 lbs. 14½ oz.	35	1-25th	Restlessness, deep sleep, great prostration	Recovery
57	3 lbs. 5 oz.	35	1-20th	Deep sleep	"
58	2 lbs. 9 oz.	40	1-25th	"	"
59	3 lbs. 5 oz.	40	1-12th	Deep sleep for nine hours, slight movements of mouth and paws	"
60	3 lbs. 6 oz.	42	1-23th	Deep sleep, occasional spontaneous movements	Death in 3 hrs.
61	3 lbs. 2½ oz.	45	1-16th	Restlessness, deep sleep, slight twitches	Death in 1 hour and 40 min.

The conclusion to be drawn from these experiments was obvious. Picrotoxine impeded and arrested the fatal effects of chloral-hydrate to a remarkable extent when they were injected together. How long after the administration of chloral-hydrate could picrotoxine be administered so as still to exert an antagonistic action? That was the next question that suggested itself, and to it the answer was sought in a few additional experiments.

TABLE VIII.—Showing the Effects of Picrotoxine when injected at Different Intervals after a Fatal Dose of Chloral-Hydrate.

No.	Weight of Rabbit.	Dose of Chloral Hydrate in grains.	Dose of Picrotoxine in parts of a grain.	Interval between Chloral Hydrate & Picrotoxine.	Effect.	Result.
62	3 lbs. 13 oz.	26	1-16th	30 min.	Sleep, restlessness	Recovery
63	3 lbs. 14 oz.	26	1-20th	60 "	Deep sleep	"
64	3 lbs. 4½ oz.	30	1-20th	60 "	"	"
65	2 lbs. 14 oz.	40	1-25th	15 "	"	Death in 2 hrs. 15m.

It thus appeared, that picrotoxine might be resorted to as an antidote to a fatal dose of chloral-hydrate, with a good prospect of a favourable issue, for about an hour after the reception of that fatal dose. This discovery seemed a very momentous one, as the wide use of chloral-hydrate at the present day makes it peculiarly desirable that an effectual and practically available antidote against its poisonous effects should be possessed. And an antidote, which can counteract double the amount of a minimum fatal dose, and overtake a poison which has had one hour's start of it, must be said to be both effectual and practically available. But the hopes which were thus not unreasonably formed, were doomed to be speedily in great measure disappointed. In ten days after the experiments which have just been enumerated, it became necessary to perform what Professor Bennett calls the crucial test, of repeating the same dose of the poison without the supposed antidote. To the rabbit which had received twenty-three grains of chloral-hydrate, and one-fortieth of a grain of picrotoxine, the same dose of the former alone was administered. It recovered just as rapidly as on the previous occasion. To the rabbit that had received twenty-five grains of chloral-hydrate, and one-twentieth of a grain of picrotoxine, twenty-five grains of chloral-hydrate were again given, and it also recovered as completely and rapidly as when the picrotoxine was conjoined with the chloral-hydrate; and so on, up to a dose of thirty-five grains of chloral-hydrate. All the rabbits that had recovered from the effects of chloral-hydrate with picrotoxine, recovered nearly as well without the picrotoxine after a sounder and less agitated sleep. The conclusion was, therefore, forced upon me, that the minimum fatal dose of chloral for rabbits had been underestimated. Whether it was that Yorkshire rabbits have more robust constitutions than

Scotch ones, or that my experiments were conducted under circumstances materially different from those under which the experiments of the Edinburgh Committee were carried on, I could not decide; but it was indubitable that our results differed to a very serious degree. A new set of experiments which was at once undertaken gave perfect distinctness to the divergence of our results.

TABLE IX.—Showing the Minimum Fatal Dose of Chloral-Hydrate in Rabbits.

No.	Weight of Rabbit.	Dose of Chloral-Hydrate in grs.	Result.
66	3 lbs. 2 oz.	30	Recovery
67	3 lbs. 11 oz.	30	"
68	4 lbs. 2 oz.	35	"
69	3 lbs. 1½ oz.	35	Death in four hours
70	3 lbs. 3 oz.	36	Recovery
71	3 lbs. 10 oz.	40	Recovery
72	2 lbs. 1½ oz.	40	Death in two hours
73	2 lbs. 12½ oz.	40	Death in two hours and twenty minutes
74	3 lbs. 1 oz.	42	Death in three hours and ten minutes
75	3 lbs. 2 oz.	46	Death in one hour and twenty-five min.
76	2 lbs. 14 oz.	46	Death in one hour and fifty-four minutes

Instead of finding, as the Edinburgh Committee did, that seven grains of chloral hydrate per pound of body weight was fatal in rabbits, I satisfied myself that nothing less than twelve grains per pound of body weight can be regarded as a fatal proportion of that drug in these animals. The only explanation of this discrepancy which I can offer is, that perhaps temperature had something to do with it. The room in which I worked had usually a temperature of about 56 degs. Fahrenheit's scale, and the rabbits, after having had chloral given to them, were always placed near a warm fire, and on cotton-wool. If the Edinburgh Committee maintained the heat of the rabbits upon which they experimented less carefully, it is conceivable that a smaller dose of chloral-hydrate would suffice to extinguish life; for Dr. Lauder Brunton has shown that warmth is most potent in hastening recovery from the effects of chloral hydrate, and in preventing death after an overdose. The chloral-hydrate used in my experiments was supplied by Messrs. Harvey and Reynolds of Leeds, and Messrs. Davy, Yates, and Routledge of London, and the solutions were prepared with scrupulous care.

To determine whether picrotoxine was really antagonistic to chloral-hydrate, and, if so, to what extent that antagonism extended, another set of experiments was clearly necessary, and these were forthwith undertaken; the minimum fatal dose of chloral-hydrate being now taken as twelve grains to each pound of body-weight.

TABLE X.—Showing the Effects of Small Doses of Picrotoxine injected with Fatal Doses of Chloral-Hydrate.

No.	Weight of Rabbit.	Dose of Chloral-Hydrate in grains.	Dose of Picrotoxine in parts of a grain.	Effects.	Result.
77	3 lbs. 3 oz.	36	1-30th	Deep sleep	Recovery
78	3 lbs. 3½ oz.	37	1-20th	Restlessness, sleep	"
79	3 lbs. 2 oz.	38	1-40th	Deep sleep	"
80	3 lbs. 3 oz.	38	1-20th	Disturbed sleep	Death
81	2 lbs. 14 oz.	39	1-40th	Deep sleep	Recovery
82	3 lbs. 1 oz.	40	1-30th	Disturbed sleep	Death
83	3 lbs.	40	1-40th	Deep sleep	"
84	2 lbs. 13 oz.	41	1-30th	"	"
85	3 lbs. 1 oz.	41	1-40th	"	"
86	3 lbs. 4 oz.	42	1-20th	"	"

These experiments made it apparent that the antagonism of picrotoxine to chloral-hydrate in rabbits is by no means so great as it was at first thought to be. Whenever the dose of the latter exceeded by four grains the minimum fatal amount, picrotoxine failed to avert death. Given in large amount, the chloral seemed to take possession of the nervous system so completely that it could not be dislodged by moderate doses of picrotoxine. And the issue of one experiment, in which a highly poisonous dose of picrotoxine, one-fourth of a grain, was given, after a fatal dose of chloral-hydrate—forty grains, did not encourage the hope that picrotoxine, in any quantity, could be employed to counteract large doses of chloral. The rabbit died, without having suffered from convulsions, much more rapidly than it would have done if left to sink under chloral poisoning. And yet, that there is a certain degree of antagonism exerted by picrotoxine against the toxic effects of chloral hydrate, is unmistakable. It does secure recovery in some cases, in which, but for its influence, death would almost inevitably ensue; and even, when it is powerless to save life, it notably controls symptoms. It rouses the cerebral centres from time to time, from that state of

torpor which chloral spreads over them. It limits the depth of the chloral narcosis, and breaks in upon it occasionally by intervals of semi-wakefulness, in which there are various spontaneous movements. It diminishes the hyperæsthesia which chloral sets up; and it prevents, to a considerable degree, that gradual production of slowness of the respiration, and that fall of temperature, which chloral constantly induces. The following table exhibits its action in keeping up the respiratory movements and the animal heat, in contrast with the unmodified effect of chloral upon these.

TABLE XI.—Showing the Effects of Chloral-Hydrate in reducing Temperature, and the Number of Respirations and the Effects of Picrotoxine in partially preventing that reduction.

No. of min. after injection.	No. 87. Rabbit weighing 3 lbs. 1½ oz., injected with 35 grs. of Chloral-Hydrate alone.		No. 88. Rabbit weighing 2 lbs. 14½ oz., injected with 35 grs. of Chloral-Hydrate and 1-25th of a gr. of Picrotoxine.	
	Temperature.	Respirations.	Temperature.	Respirations.
5	100.4	60	100.0	72
10	99.6	67	99.1	72
20	98.6	50	98.4	68
50	97.4	43	98.2	63

300	—	—	94.3	60
320	—	—	Ultimately quite recovered.	

[To be continued.]

CROUP AND DIPHTHERIA.

By WILLIAM CUMMING, M.D., Edinburgh.

THE question as to the identity of membranous croup and diphtheria is worthy of the attention it has recently received; but, I confess, I have some difficulty in understanding how the two diseases can be ranged under the same category. Many years ago, I saw a large number of cases of membranous croup, and its characters were of the most pronounced kind.

1. The type was sthenic. 2. The exciting cause was atmospheric, i. e., cold and damp. 3. The treatment most successful in my hands, was antiphlogistic, viz., tartar emetic in frequent and nauseating doses. 4. It was non-contagious. I never saw two cases in one family either occurring simultaneously or in immediate succession. 5. It was never followed by paralysis or other consequences affecting the nervous system. 6. It was limited to a certain age; never in my experience occurring after twelve years of age. 7. The membrane, as ascertained by *aut mortem* examinations (which were sufficiently frequent), was firm, tough, tense, and of a light kid colour, and was strictly limited to the laryngo tracheal tract, at least in its upper part, though it not unfrequently passed downwards into the bronchi in the form of plastic bronchitis. The disease never invaded the pharynx, fauces, or nose.

All who have seen much of diphtheria cannot fail to remark how totally different pronounced cases of it are. 1. The type is asthenic. 2. The exciting cause is septic. 3. The treatment is antiseptic, nourishing, and stimulating. 4. It is markedly contagious, and, unless the most stringent precautions are taken, attacks, and proves fatal to other members of the family, or those in direct contact with it. 5. Nervous symptoms, and especially paralysis, are not unfrequent consequences, and are always to be feared. 6. It has no respect for age. 7. The membrane is ash grey, friable, in many cases almost pultaceous, and generally soft. It is seldom limited to the laryngo tracheal tract, but as frequently as not extends to the pharynx, fauces, and nose, and often begins there, passing downwards, which membranous croup never does.

Typhus and typhoid fever are recognised now by sufficiently distinctive characters, but they are, in my opinion, not more, or indeed so distinct, as are membranous croup and diphtheria.

A COTTAGE INFIRMARY is to be built at Mold. The Duke of Westminster, Mr. P. B. D. Cooke, and Mr. W. B. Buddicom, have each subscribed £100, and others smaller amounts, making in the aggregate about £500.

OBSTETRIC MEMORANDA.

UNITED TWIN MONSTROSITY.

ON March 23rd last, about 8.45 A.M., I was called to Mrs. B., who was in labour with her fourth child. She had been all night in pain, and at my arrival the head presented at the brim in the first position. The membranes were unruptured, and the os dilatable. On rupturing the membranes, the head slowly descended, but, to my surprise, remained for about two hours and a half on the perineum, although the pains were severe and her previous labours had been very easy. As the head seemed as though it would never pass the perineum, I pushed it and the soft parts of the mother back over the head, which emerged with the face to the sacrum in the usual way. The head being thus born, the fingers could be easily placed round the neck, and any justifiable amount of traction used; but the body refused to descend even in the least degree. However, after a time, the head of itself rotated to the position of the occiput to the sacrum; and I found that, by forcing it directly forwards and upwards, gradually the shoulders, back, nates, and finally the feet, were born. It then became evident that there was a second child attached to the abdomen of the first, thus causing this peculiar mode of delivery. The second child was born first feet, then nates, and finally vertex, in a similar way to an ordinary abdomino-anterior footling case. I thought it well to record the mode of delivery in this case, as it shows the way in which, in vertex-presentations, united twins can be born; that is, by the head of the first child passing, becoming fixed against the pubic arch, and the rest of the body coming down by a natural process of version. The children were two perfect female infants perhaps rather smaller than the average size, united in the median line by a broad band extending from the lower part of the sternum to the umbilicus, the abdominal seeming continuous. The umbilicus, cord, and placenta were single.

Each infant had the two upper central incisors developed. The first breathed during birth, which was necessarily prolonged and difficult; the second was quite still-born. G. PERCIVAL HADLEY, M.D.

SURGICAL MEMORANDA.

PRELIMINARY TRACHEOTOMY.

MR. UNDERHILL'S suggestion, in the JOURNAL of March 13th, "that in future major operations about the mouth and air-passages tracheotomy should be performed as a first step", is one the value of which has for some time been recognised by continental surgeons, and especially by Professor Langenbeck of Berlin. He found, however, that the ordinary tracheotomy-tube, however well it might seem to fit, did not sufficiently answer the purpose of preventing blood from trickling down the air-passages. The following method was, therefore, suggested by one of his assistants (Dr. Trendelenburg), and found to answer remarkably well. An ordinary tracheotomy-tube was surrounded by a tightly fitting thin India-rubber bag, which communicated through the wound in the trachea by means of a small tube. After introduction, by blowing through this tube and then applying a ligature, the bag surrounding the tracheotomy-pipe was inflated with air, and thus adapted itself with the utmost precision to the parts around, and so effectually barring the way to the passage downwards of any material whatsoever. The idea was very simple, and was found to answer perfectly, thus doing away with all the inconvenience and not a little of the danger attendant upon operations in this region.

CHARLES F. HUTCHINSON, M.D., Scarborough.

TREATMENT OF SPINA BIFIDA.

HAVING lately cured a case of spina bifida, on the plan advocated by Dr. Morton of Glasgow, I beg to add my testimony in favour of his treatment. On November 1st, 1874, I attended Mrs. T., in labour with her second child, which was born a few minutes after my arrival. It was a plump, well-nourished boy. Over the three upper lumbar vertebrae was a tumour, of the size of a peach, which had ruptured with the expulsive efforts of parturition, and part of the contents had escaped from the sac. Careful that too much fluid should not drain away, I applied a pad of cotton-wool over the opening, and a broad binder. Two days afterwards, it had partly refilled, and, when the child cried, became tense. It was semi-transparent, and had a pinkish appearance except at the upper part, where on each side there was a bluish spot, about the size of a sixpence, which, the mother remarked, were like two eyes. The child cried whenever firm pressure was made over the

tumour. The nature of the case having been explained to the parents they were anxious for the operation to be done. On November 19th, I punctured the sac with a grooved needle, and drew off part of the fluid, a cotton-wool pad and binder being applied. The operation was repeated four days afterwards. On neither occasion did the child suffer from constitutional disturbance. On the 28th, after drawing off half the contents through the needle of a subcutaneous syringe from the bluish spot, at the upper and left side of the tumour, I injected through the same needle half a drachm of the iodo-glycerine solution (previously warmed at the fire to liquefy it). Flexile collodion was painted over the minute opening, and a piece of lint dipped in olive oil, with a pad of cotton-wool, laid on it; the binder firmly securing the whole. The child cried lustily after the operation, and in about ten minutes suddenly turned pallid in the face, the nurse exclaiming that it was dying. Fifteen drops of brandy in a teaspoonful of water were given, and the little fellow was soon sleeping soundly in his mother's arms. Gradual thickening of the contents took place, and on January 4th, 1875, complete consolidation was present in every part, except the bluish spot on the right side, where a little fluctuation was felt. Fifteen drops of Dr. Morton's solution were injected into it with the subcutaneous syringe; and by the end of the month the cure was complete. The child is now (March 20th), in good health, the only appearance noticed on the back being a corrugated and hard condition of skin over the site of the former tumour.

Newcastle-upon-Tyne.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN
THE HOSPITALS OF GREAT BRITAIN.

CHARING CROSS HOSPITAL.

Psoas Abscess, from Caries of Anterior Part of Sacrum,
Communicating with Spinal Canal.

(Under the care of Mr. BARWELL.)

[From Notes furnished by Mr. JOLLY, Assistant House-Surgeon.]

F. ADAMS, aged 23, footman, was admitted into Charing Cross Hospital, under the care of Mr. Barwell, on January 2nd, 1875. He had come to the hospital complaining of rupture. The tumour was as large as half a hen's egg; was situated below Poupart's ligament, on the left side, and inside the femoral vessels, in the situation of crural hernia. The skin over it was red; much manipulation had been used to return the swelling, which was elastic, had a distinct impulse on coughing, and the greater part of it, except a harder remnant, could be returned within the abdomen. Mr. Barwell saw him in the casualty-room, diagnosed abscess, and ordered him to be admitted. There was no gonorrhoea, no sores on the leg, no angular curve, nor tenderness on percussing the spine. He stated that he had always been of a weak constitution; could not remember having received any blow, but, about twelve months ago, on lifting a heavy plate-chest, felt a severe pain in his back, which, however, passed off in a few days. Three weeks previously to admission, he noticed a small lump in the groin, which gradually increased, but which was and had been quite painless.

January 12th. An opening was made into the red part of the swelling. Twelve ounces of thick yellow pus, without any fætor, escaped. The wound was closed with a pad of lint secured by a spica bandage, and rapidly healed; the man felt much relieved.

January 16th. He got up and walked about the ward; but, in rather more than an hour, felt sick, with pains in the spine and head. The tongue was soon afterwards found to be furred; temperature, 103.

January 18th. During a fit of violent coughing, the wound in the abscess reopened, and gave exit to a large quantity (probably more than a pint) of pus; this gave great relief, but the temperature only fell one and a half or two degrees.

January 26th. Mr. Barwell examined the opening with a probe; he found, first, a passage leading by the inner side of the vessels and of the bone to the back of the femur; secondly, with some difficulty, another passage, which led upwards and inwards into the pelvic cavity. From this, he considered that the disease was caries of the sacrum.

February 16th. During these three weeks, there had been free discharge of pus. The temperature varied from 101 to 103. The abscess was syringed daily with carbolic acid lotion (1 in 60).

March 28th. He had been becoming thinner and weaker, with the

morning and evening variations of hectic temperature; he had diarrhoea, but never passed any pus *per rectum*. About three weeks ago, he complained of pain in the right thigh, which became flexed on pelvis, but for which no cause could be detected. Gradually losing strength, he became worn out, and died at the above date.

Necropsy.—All the viscera were healthy, except a few cheesy tubercles (?) in the lungs. On taking out the abdominal contents, the front of the sacrum and the lower lumbar vertebra were found carious, the pus having passed into the sheath of the left psoas, and gravitated downward to the groin. On the right side, pus had also found its way into the psoas, the muscle being softened and swollen; but this was of recent date, and may have accounted for the pain latterly experienced in the right thigh. Although the whole front of the sacrum was carious, the brunt of the disease chiefly fell about the second and third division, and here, namely, about the lower part of the second bone, was a sequestrum, which, on being removed, exposed a hole, singularly round, almost like a gun-barrel. The finger passed into this, detected at the bottom a fissure, which appeared to lead into the spinal canal. The front of the sacrum was removed with the saw, and the fissure, on being exposed, was found to communicate with that cavity. Pus continued to ooze from it even after being sponged away.

This case is interesting, as a guide among the obscurities of intrapelvic abscess, especially in the absence of spinal symptoms; also as an instance of the rare conditions found on *post mortem* examination.

SELECTIONS FROM JOURNALS.

TOXICOLOGY.

POISONING BY SAUSAGES.—Dr. L. Müller, gives in the *Deutsche Zeitschrift für pract. Medicin*, Nos. 1, 2, and 3, 1875, the history of a remarkable case of sausage-poisoning, at Middelburg in Holland, the particulars of which were communicated to him by several Dutch physicians. In March 1874, nearly 400 persons became ill in the course of a few days, after eating liver-puddings obtained from a certain butcher's shop. The symptoms, which appeared a few hours after eating the sausages, consisted of *malaise* and vomiting, diarrhoea with watery and very foetid discharges, at first yellow, afterwards of a grass green colour, colicky pains in the intestines, with, in many cases, pain in the epigastrium and tenesmus, urgent thirst, and great diminution of the secretion of urine. The fever was rather high; the temperature exceeded 39 per cent. (102.2 deg. Fahr.); the pulse was small, 100 to 120. Herpes labialis appeared off and on. After a few days, apparent convalescence set in; but was, in many cases, interrupted for several days by a recurrence of the symptoms, generally, however, without vomiting. Nothing is said as to the state of the spleen. Sometimes the disease finally assumed an intermittent character. Of 343 patients whose cases are recorded, 6 died. *Post mortem* examinations were made in two cases; but these, as well as chemical and microscopical examinations, and experiments on animals by feeding them with the sausage-meat, gave only negative results.

THERAPEUTICS.

TREATMENT OF HOOPING-COUGH.—R. Meyer of Zürich says (*Schweizer Correspondenz-Blatt*, and *Allgemeine Med. Central-Zeitung*, No. 93, 1874), that whooping-cough commences with a catarrh of the nasal passages, which, passing downwards, affects the fauces and the larynx. Sometimes it passes to the bronchial tubes, and produces bronchopneumonia. The "whoop" is not absolutely characteristic of whooping-cough; it depends on the preponderance of the otherwise comparatively feeble contractors of the glottis over the dilators, and, while it is absent in the milder forms of pertussis, occurs in other inflammatory affections of the larynx. Meyer attaches most importance to the local treatment. A laryngoscopic examination should be made, and good ventilation and isolation of the patient are recommended. In the catarrhal state, while the nasal mucous membrane alone is affected, he advises the local application once or twice daily of a one or two per cent. solution of nitrate of silver; in adults, he uses a nasal douche, with a one per cent. solution of chlorate of potash. Sudorifics, alcoholics, smoke, and anything that may irritate the nose, are to be avoided. In the spasmodic stage, it is necessary to act directly on the mucous membrane of the fauces and entrance of the larynx with nitrate of silver, alum, and tannin; the two latter are to be mixed with two parts of powdered talc. If they cannot be blown in, the patient may inhale them; the operation is to be repeated from three to four times daily for three or four minutes at a time, the tongue being held down. Dr. Meyer also uses for inhalation a solution in water of chlorate of

potash or alum (2 per cent.), and tannin or carbolic acid (1 per cent.) In children under three years old, the best plan is to touch the affected parts with mild astringent solutions. The local application should be continued after the paroxysms of cough had ceased, as irritability remains, and is liable to produce a return of the attack, and even vomiting. Nüsscherer of Zürich (*ibid.*) writes on the same subject; and, in support of the view that the paroxysms of cough are dependent on paralysis and not on spasm of the glottis, he cites the case of a man under the care of Professor Biermer, in whom, though he had paralysis of the vocal cords, attacks resembling those of whooping-cough occurred. In speaking of the treatment, he says that opium and belladonna did not cut short the disease, but only weakened the individual attack, by producing an unpleasant toxic state. He did not see any markedly good results follow the use of bromide of potassium or of chloral-hydrate. Dr. F. Vogelsang strongly recommends, in Betz's *Memorabilien*, No. 10, 1874, the use of bromine in the nervous stage of whooping-cough. The atmosphere of the patient's room to be impregnated with the vapour of bromine, and a tablespoonful of the following mixture is to be given from one to three times daily in water: R Bromide of potassium half a drachm; water, about three or four ounces.

THE TREATMENT OF DIARRHŒA.—In a paper in Virchow's *Archiv*, vol. lxi, Dr. Hartsen observes that diarrhoea of all sorts goes along with an irritable state of the intestinal canal, and any increase of this irritability is to be carefully avoided. He considers that the more usual astringents are, in addition, irritants; and he instances among them the salts of lead, zinc, and bismuth. In all cases, soothing means should first be adopted; and of these, warm applications to the abdomen, in the form of bread poultices, or fomentations, are perhaps the best. The chief medicine recommended is opium, which soothes, but, in large doses, interferes with digestion. If the diarrhoea be so violent as to hinder the absorption of opium introduced into the stomach, then morphia should be injected subcutaneously. Of equal importance is the diet. If the person be strong, everything, both solid and fluid, should be withheld; but, where this cannot be done, the food should be of the lightest and simplest. The author specially refers to rice and arrowroot as simple vegetable diets, while any animal food given should be free from fat. Milk should not be too much used, and in any case should be boiled.

SURGERY.

FLEXIBLE CATHETER FOR IRRIGATING THE BLADDER.—Dr. Stuart Eldridge, in the *New York Medical Record* of December 1st, 1874, describes as follows an instrument for the irrigation of the bladder in certain cases in which the rigidity of the ordinary instrument renders its use inconvenient or impracticable. Through the side of a soft India-rubber catheter (No. 10 to 12, English gauge), an opening is made by a broad needle, or the point of a lancet, at the distance of an inch and a half from the open end of the tube. Through this opening is forced the point of an ordinary gum catheter of such size as to lie very loosely in the bore of the rubber instrument. In passing the smaller catheter into the larger one, the surface should be well wetted, and the stylet retained until the point of the gum instrument has passed into that of the rubber one, when the stylet should be removed, and the instrument is ready for use. In a similar manner, an irrigator may easily be extemporised from an ordinary metallic catheter, either male or female, by adjusting upon the open end of the instrument a short piece of rubber tubing, through the side of which a gum catheter is passed in the manner described above.

VERTICAL LUXATION OF THE PATELLA.—In the *New York Medical Record* of December 1st, 1874, Dr. S. P. Davis reports the case of a servant-girl who, while sitting upon the floor, suddenly reached forward to seize a child, and found immediately afterwards that she was unable to move her leg. On turning the patient upon her back, the left patella was seen to be turned upon its inner edge, so that its upper surface looked towards the opposite knee. It was rigidly fixed, and the limb was entirely helpless. The patient was etherised as she lay upon the floor. The whole limb was then elevated by an assistant, so as to relax the muscles in front of the thigh, and, by forcibly crowding down these muscles towards the knee with one hand, manipulating the patella at the same time with the other, reduction was effected with the utmost ease.

BEQUEST.—By the will of the late Jane C. Murdoch, Greenock, £100 has been left to the Larbert Imbecile Institution, and £100 to the Greenock Infirmary.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, APRIL 17TH, 1875.

COUGHS.

THERE are few objective phenomena more frequently presented to the notice of the medical man than cough. There are many varieties of cough, according to causation. In its simplest form, cough is a strong expiratory effort to get rid of some irritant matter in the respiratory tract. If a crumb get into the larynx, cough is at once induced. If one cough be insufficient for the expulsion of the intruder, another follows, and then another, it may be, until a prolonged fit of coughing is induced. Finally, the offending matter is expelled; or, in rare cases, it remains, the parts becoming habituated to the presence of the foreign body, and only at intervals do there occur attempts at expulsion.

A cough consists of, first, a quick inspiratory movement, then the diaphragm is fixed, and a strong action of the expiratory muscles follows. So forcible is the effort at times, that matters are expelled thereby from the abdominal cavity. The effect of the cough is to expel the contents of the air-tubes into the mouth, whence they are driven by another muscular movement. Under these circumstances, cough is an useful natural effort; but, when occurring under other circumstances, it may call for active remedial measures.

Cough may be divided into two divisions: the one, that of thoracic origin; the other, that of extrathoracic causation. When of thoracic origin, cough may be caused by irritation existing in the air-tubes, in the structure of the lung, in the pulmonic circulation, or by some growth or abnormal fluid accumulation within the larynx. According to its causation, and the condition under which it appears, so will be its appropriate treatment.

One of its commonest forms is that of its association with a cold. The mucous lining of the respiratory tract is dry, sensitive to slight impressions, so that a current of cold air blowing into the air-passages will prove a source of irritation, as well as a means of irritation itself. Under such circumstances, cough is repeated, uncontrollable, and persistent. If the condition be that of mere dryness with much irritability, sedative remedies are indicated, as paregoric, etc. If, however, it be but the first stage of inflammation of the mucous membrane, it is accompanied by a small amount of expectoration—a tenacious mucus streaked with blood. Here the condition must be met by nauseant remedies, especially those which also act powerfully upon the skin. By the administration of such relaxants, the turgid condition of the mucous membrane is diminished; free secretion follows; the mucus is more easily dislodged; and the first step towards recovery is secured. Having thus secured free secretion, or, as it is termed, “loosened” the cough, then the nauseant expectorants may be abandoned in favour of the stimulating expectorants. It is useless, however, to give squill, carbonate of ammonia, and senega, in the first stage; they may well follow the use of tartar emetic, ipecacuanha, or iodide of potassium with acetate of ammonia, but they may not take their place. The action of nauseant expectorants may often be usefully aided by the application of large hot poultices round the thorax; and, if the cold be fixed, counterirritation by croton-oil liniment, etc., is often of great service. A free secretion having been induced, then stimulating expectorants must be resorted to, and the

system sustained by stimulants and beef-tea, milk, etc. The difficulty of breathing through the obstructed air-tubes, the disturbed and broken sleep, tax to the utmost the powers of endurance. Exhausting as this action may be, it is not good nor safe to give opium here. Not only would it tend to arrest the bronchial secretion, but it would tend to check those voluntary respiratory efforts which are often absolutely necessary. The patient could sleep without the aid of narcotics, if the air-tubes were but unclogged. As it is, however, the tubes must be cleared by cough, or the chemical interchanges carried on by respiration must cease. As a consequence of this demand upon the powers, bronchitis is a very fatal affection in the very young, the aged, and the feeble.

At other times, cough is not constant, and only appears under certain conditions. Such, for instance, is the morning cough common in cold weather, especially in a dust-laden atmosphere. The mucus which has gradually formed during the night, and to some extent the day before, is dislodged from the spots upon which it has accumulated, and which have become accustomed to its presence, and, in the movements of dressing, especially in stooping, slides on to some new locality, where the irritation so caused at once sets up cough. Piece by piece, the masses are dislodged in repeated series of coughs. At last, the air-tubes are cleared, and the cough disappears, to return next morning. When the source of irritation is laryngeal, direct applications to the morbid surface will do away with the irritation and its consequent reflex action—cough.

At other times, cough is due to the presence of some growth in the structure of the lung, acting as an irritant—a true thorn of Van Helmont. Such is the cough of a tubercular mass. This acts as an irritant to the terminal nerve-fibrils in the lung-tissue, and a series of reflex muscular actions is induced. It is obvious, however, that here the cough is useless, and the expulsion of the irritant matter is not to be accomplished. The cough is troublesome and exhausting, while it is futile. Under such circumstances, then, it is desirable to resort to some agent which will lessen reflex action. These agents are to be found amidst those neurotics which lessen nerve-action. Such are opium, bromide of potassium, hydrate of chloral, etc. These agents directly arrest the action in nerve-cells, and possibly lessen the conducting power of nerve-fibrils. Especially do they arrest those reflex actions which entail a pretty long course over different sets of nerve-fibrils. In the case, then, of cough which is excited by the presence of a growth in the lung-tissue acting as a foreign body, and which is obviously unavailable for the expulsion of the irritant matter, we must resort to these neurotic agents. To be efficient, these agents must be given continuously; and this entails some evil consequences. Opium is very useful but very objectionable in cases of tubercle, from its destructive effects upon the appetite. Nevertheless, it is desirable to allay the cough by some means.

When the tubercular mass has softened, and, by ulceration around its periphery, opened into an air-tube, then the cough is useful in procuring the expulsion of the semifluid mass. Here it is not desirable to allay the cough, unless it be absolutely indicated in order to admit of sleep. For the purpose of procuring rest, narcotics may be administered at bedtime; or, if there be a condition of hyperæsthesia leading to excessive and uselessly persistent cough, then they may be given in small doses during the day. Some care is requisite, however, to avoid the unnecessary resort to these agents.

When cough is due to a state of congestion of the pulmonic circulation, as it often is in disease of the heart, sedatives are undesirable and pernicious. This cough is dry and harsh, and may be induced in most persons by running rapidly up stairs. The excessive amount of blood in the thorax acts as an irritant, and so induces cough. Doubtless, in these conditions, opium will give immediate and temporary relief to the cough; but it will produce such an effect upon the heart and circulation as will but aggravate the state of matters. Not only so, but it interferes with nutrition, and the powers fail: a very undesirable condition of matters in affections of the heart. Here the cough must be met by

rest, and by those agents which increase the power of the ventricular contractions. By such means, the cough will be relieved at the same time that other good results are secured.

If, however, the cough take its origin in the presence of an aneurism, the sedatives, combined with measures which lower blood-pressure generally, and so diminish the tension in the walls of the aneurism, are clearly indicated. Where there is a growth in the mediastinum which excites cough, sedatives are also to be resorted to. If there be any accumulation in the pleural cavities, the fluid must be dispersed by absorption or other means; and in the meantime the cough may be soothed by anodynes.

Cough is often extrathoracic in its origin. Not uncommonly it is induced by an elongated uvula, which tickles the epiglottis and the parts around, and so causes fruitless but troublesome cough. Here, obviously, the only satisfactory line of treatment is to remove the cause by amputating the uvula.

So persistent is the cough of pharyngeal ulceration, especially in its follicular form, that it was commonly taken for the cough of pulmonary tuberculosis, until the late Dr. Horace Green demonstrated its true nature. By a most interesting series of observations, he clearly indicated the nature of these cases; and, by applications to the seat of the ulcerations, he caused them to heal, and, in so doing away with the cause of the cough, cured it too.

At other times, cough is the consequence of irritation existing in the ear, and is termed ear-cough. Of course, for the successful treatment of this form of cough, the services of the aural surgeon must be invoked.

Cough is very commonly induced by irritation in the abdomen. Specially is this seen in the cough of gastric irritation, frequently associated with an undue consumption of alcohol. Usually, it is a morning-cough, and passes away after some alcohol has been imbibed, and more so still if some food also be taken. In such cases, the correction of the habits, and the use of tonics with a mineral acid, will furnish the best line of treatment. At other times, cough marks a state of intestinal irritation, as diarrhoea.

Cough is also associated with irritation in the uterus in some cases, and here it may be necessary to subject the uterus to local applications ere the cough can be subdued. In all these cases, the only method of treating the cough, besides the removal of the cause, is the administration of those agents which lessen reflex action by their effects upon the nervous system.

Sometimes cough is due to certain modifications in the nervous system itself. Such is the cough which is found in young girls at puberty, and which causes much concern to anxious parents. It is a dry, short, persistent cough, in many respects resembling the cough of tubercle. It is not accompanied by any of the physical signs of tubercle, nor by any rise of temperature; in this, it differs from the tubercular cough. As, however, it is often accompanied by much wasting and by sleeplessness, due to the cough, it frequently causes much alarm. If the friends be injudicious, it may be impossible to remedy this cough. The measures to be resorted to are combinations of bromide of potassium with tonics. If there be ovarian excitement, and there be an erotic element in the case, the bromide may be pushed into full doses. If there be rather an irritable or adynamic condition of the nerve-centres, then chalybeates with vegetable tonics are indicated; and the bromide may be given at bedtime, or hydrate of chloral may be resorted to instead. These cases are troublesome and unsatisfactory; usually they persist, more or less controlled by remedial measures, until the attention is directed to some other absorbing matter, and then the cough disappears silently and unnoticed.

At other times, cough is a simple neurosis, and, as such, must be treated by the ordinary measures of tonics, stimulants, good food, etc.

Such, then, are the chief varieties of cough; whooping-cough not being a neurosis so much as a specific ailment. In all of them, there is a tendency to persist merely as a habit. For the correction of the

factor formed by habit, the exercise of the will is essential. In children, especially those of nervous habit, it is often as difficult as it is desirable to induce this action of will. It may often be assisted by the promise of a reward; and even some deterring power might be brought to bear where the will seems wanting. The desired volition may be further aided by good food, wine, and tonics. In adults, the force of habit rarely presents difficulties, unless it be in that intractable class of cases termed hysterical. If cough be an involuntary action in its origin, still some influence can be exercised over it by the will. This is seen in the different manner those persons cough, in cases where there is some phlegm to be raised, who have given attention to the matter, as compared with those who have not. The latter often have distressing fits of coughing, because they do not take pains to insure a good deep inspiration preparatory to the expiratory effort. We all know how ineffectual is the repeated cough where no such inspiration has been achieved; it goes on until at last either the contraction of the bronchial fibres has extruded the mass, or a convulsive inspiration enables the mass to be expectorated. Others, again, when they feel the inclination to cough becoming irresistible, secure a deep inspiration, which results in the mass being dislodged at the first expiration. Even if the first effort be not successful, the condition of inflation of the chest renders the cough less painful, and enables a second inspiration to be more easily secured; and it is of a fuller character, and consequently more efficient. In cases of chronic bronchitis, it is of much moment to teach the patient how to cough in the most effective and least distressing manner.

AN outbreak of cholera is said to have occurred at Oude, and is causing some mortality among railway passengers.

THE British Medical Benevolent Fund has received a donation of £100 from Dr. Charles Shrimpton, of Whitehall, and formerly of Paris.

THE *Student's Journal* mentions a case of death from inhalation of ether, stated to have occurred in Manchester. The case is not officially reported. We shall hope to receive details for publication.

A WELL-KNOWN and ably conducted medical journal, the *Deutsche Klinik*, which first appeared in 1849, has come to an end with the life of its founder and editor, Dr. Alexander Götschen.

IT is stated that a serious escape of sewer-gas has occurred at the new public offices in Downing Street, London, so that they cannot yet be occupied.

AT the Society of Medical Officers of Health this (Saturday) evening, Dr. Alfred Carpenter of Croydon will read a paper on the Practical Power of Soils, Air, and Vegetation to purify the Sewage of Water-Closet Towns.

THE German surgeons held their fourth annual congress in Berlin last week, under the presidency, as heretofore, of Professor von Langenbeck. The meetings commenced on April 7th, and ended on the 10th.

THE execution of Alfred Heap, the quack doctor, who was sentenced to death at the Liverpool Assizes, has been fixed to take place at Kirkdale Gaol on Monday the 19th. His friends are making a vigorous effort to obtain a reprieve, and a memorial with that object has received over 4,000 signatures, including those of thirty clergymen.

THE President of the Local Government Board, in a letter to the St. Pancras Vestry, stated that, in the Bill which he proposes to bring in during the present session for the prevention of the pollution of rivers, he hopes to introduce a proviso which will have the effect of preventing the contamination of rivers and canals by sewage and other impurities.

AT a meeting of the Council of University College on Saturday last, Sir Henry Thompson was appointed Emeritus Professor of Clinical Surgery, on his retirement from the duties of the hospital. The post is not to be altogether devoid of duty.

WE understand that it is the intention of the Society of Apothecaries to institute, during May and June next, at their Hall a limited course of lectures on State Medicine. These lectures will be delivered by Dr. De Chaumont, Assistant-Professor of Hygiene at the Army Medical School at Netley.

A BILL to amend the Medical Act, 1858, so far as relates to the registration of women who have taken the degree of Doctor of Medicine in a foreign University, proposes to make registerable the degrees of the Universities of France, Berlin, Leipzig, Berne, and Zürich. It gives the General Medical Council power to add to the schedule, and to register such degrees, subject to the fifteenth section of the Medical Act. It is introduced by Mr. Cowper-Temple.

A NEW variety of special journal has appeared in France, *The Annals of the Diseases of the Ear and Larynx*. The first number includes an attempt at the Classification of the Diseases of the Larynx and Pharynx, by M. Isambert; Amygdalotomy, Part 1, by M. Germain; Menière's Disease, by M. Lacharrière; Rhinoscopy, by Dr. Krishaber, Part 1; Naso-pharyngeal Polypus, by M. Labbé; Laryngopathy of the First Phase of Syphilis; Parasitic Otitis; etc.

A COMMITTEE, consisting of Professors Hildebrandt, Litzmann, Martin, Schwartz, and Spiegelberg, met in 1873, at the instance of the Prussian Government, to agree on the principles of a new hand-book for midwives in the kingdom. The preparation of the work was entrusted to Professor Litzmann, who has completed it; and the committee met again last week in Berlin for the purpose of revising it. Dr. Aveling some time since announced a similar manual for the midwives of this country; but it has not yet made its appearance. It would seem to be much wanted.

A RESULT OF EXPERIMENT ON ANIMALS.

DR. OGILVIE WILL publishes in the *Edinburgh Medical Journal* for April a very interesting case of strychnia-poisoning successfully treated by chloral-hydrate. Interesting in many ways, it is especially so as one of the earliest practical applications to the saving of life and mitigation of pain of the latest researches on animals of the Edinburgh Committee on behalf of the British Medical Association, for which last year's grant was appropriated.

"The result of the treatment adopted in this case seems to me to be a proof that the antagonistic action of chloral-hydrate to strychnia, proved, by the experiments of the Committee appointed by the British Medical Association to investigate the antagonism of medicines, to exist in the lower animals, also shows itself in man; and I think that it is strong testimony in favour of some of the conclusions arrived at by Dr. Bennett and his co-workers, as given in the *BRITISH MEDICAL JOURNAL* of January 23rd, 1875. One it at any rate corroborates: 'That, after a dose of strychnia has produced severe tetanic convulsions, these convulsions may be reduced both in force and frequency by the use of chloral-hydrate, and consequently much suffering saved'; and, considering the undoubted severity of the symptoms, without laying much stress on the repeated statement of the patient that he had taken 'not less than four grains of the poison', I cannot but think myself justified in asserting that it goes far to prove the correctness of another, viz., 'That, after a fatal dose of strychnia, life may be saved by bringing the animal under the influence of chloral-hydrate'."

THE WEATHER AND THE SOUTHERN HEALTH-RESORTS.

THE *Berliner Klinische Wochenschrift* says: The severity of the winter just past has unfortunately made itself severely felt in the climatic health-resorts. From the *Oesterreichische Badzeitung* we learn, that at Meran there was a quite unusual fall of snow in November, followed by extraordinary cold; and since then, the ordinary steadiness of the

climate has been wanting till the spring, though the variability has been somewhat mitigated by the calm. Even Nice and San Remo have been for weeks together without the sun and their usual warmth; in Catania alone was there a steadily warm winter, curtailed in February only by nine days of rain. These statements are confirmed by private information, which we (*Berliner Klin. Woch.*) have received. At Nice, Mentone, San Remo, and Pisa, there were cold and stormy days in the beginning and middle of February: in the three first named places the thermometer sank in the course of the winter to -2 and even -3 cent. (28.5 and 26.5 deg. Fahr.); and at Naples and Capri there was similar weather at the end of February and beginning of March.

THE WOUNDED IN WAR.

SOME printed "Proposals for the Formation of an Army Hospital Corps", by "Unitas", have been forwarded to us. The chief feature of the plan is, that every company of Infantry, Royal Engineers, Royal Artillery, and Cavalry, should maintain at least one orderly, who should wear the dress, and be an unit in all respects, of the company, until his promotion to the grade of non-commissioned or warrant officer, when he should leave his regiment, and adopt the dress and equipment of the Army Hospital Corps properly so called. The regimental or company orderly should have two years' previous service in the ranks; should be sent for training to a general hospital; and then, if found fit after examination, should receive a certificate as a qualified orderly. It is presumed that it is intended by the plan set forth that, when not required for hospital duties, the orderly should be employed in the ranks as a soldier; for among the proposals is one that, when not employed on hospital duty, he should wear the Geneva badge on his arm over his regimental uniform. The plan proposed appears to be a very feasible one, if it be really intended as an addition to the Army Hospital Corps as at present constituted. If it be intended as a substitute for it, we fear it would hardly be found to answer the expectations of its author. One of the evils which the establishment of the Army Hospital Corps was intended to prevent, was the little reliance that medical officers could place on having suitable hospital attendants, or any at all, in sufficient number, when they depended on the regimental ranks for them. It is notorious that, in time of war, the combatant wants always overrode the medical wants, the accession to the fighting ranks of every soldier that could use a firelock being regarded as a matter of vital importance; and that, in time of peace, military considerations were constantly clashing with medical considerations, so far as concerned the soldiers employed in hospital duties. It was felt that the only way to prevent this discord, and to provide satisfactorily for meeting the wants of the sick, was to have a special independent corps of men thoroughly trained in hospital work, and maintained for that alone—not even carrying rifles, so that they might not be at any time employed in the ranks as combatants. There is no argument that can be brought forward for any one special corps in the army, that cannot be brought forward with greater force for a regular corps of hospital attendants on the sick. If the plan proposed, however, be additional to the existing Army Hospital Corps, then it appears to meet a want which will be surely felt in case this country should become involved in an European war. The present strength of the Army Hospital Corps is on all sides stated to be insufficient for the hospital duties which it has to discharge. All the men of the corps will certainly be wanted for the general hospitals in time of war; and where then will be the trained men for doing the responsible duties of giving the first assistance to the men wounded in action, of carrying them to the hospitals in the rear, and attending to their wants on the way? We believe we are right in saying that there is no army in Europe without a specially organised establishment designed to meet these urgent wants, except our own. The proposals of "Unitas", if carried out, would in some degree afford a provision for them.

PROFESSIONAL PERILS.

WE regret to announce the death of Mr. J. D. Hill, surgeon to the Royal Free Hospital, at the early age of 35. It occurred at his resi-

dence, Guilford Street, Russell Square, on Wednesday morning last, and was occasioned by erysipelas, cases of which disease he had been lately treating in the hospital. Mr. Hill received his medical education at Guy's Hospital, obtained the membership of the College of Surgeons in 1859, and the fellowship (by examination) in 1867. After filling the office of house-surgeon to the Royal Free Hospital, he was a few years since elected surgeon to that institution. He was also surgeon to the Orthopædic Hospital in Oxford Street. Mr. Hill was well known as an active and hard-working surgeon, and was a frequent contributor to medical journals, reviews, and transactions. His premature death from disease contracted in the course of his duty, adds another to the long list of medical men who have fallen victims to the risks inherent to their profession.

SCIENTIFIC RESEARCH.

IN the course of his recent Faraday Lecture on Liebig's Contributions to Experimental Research, Dr. Hofmann especially pointed out that Liebig's first experiments on alcohol, and the action of chlorine upon it, led to the discovery of chloral and chloroform, two compounds now in continual use for the alleviation of human suffering; an illustration of the practical advantages ever following the pursuit of truth. Of the former compound, in 1868, probably there was not a kilogramme in existence in the whole world; now the factories of Berlin alone produce 100 kilogrammes daily. The object of the investigation of alcohol was to elucidate the constitution of the compound, and gave rise to a long protracted contest between Dumas and Boullay, on the one hand, who considered ether and alcohol to be hydrates of olefiant gas, and Liebig, on the other, who regarded them as derivatives of a radical to which he gave the name of ethyl. It ended in a signal victory for Liebig, and an universal adoption of his theory.

EXAMINATION PAPERS.

AT Bow Street police-court on Saturday, Samuel Cowap was charged on remand before Mr. Flowers with inciting George Austin to steal an examination paper of the Pharmaceutical Society from Messrs. Stevens and Richardson, printers, of Great Queen Street. The prisoner, who was a chemist's assistant, had obtained the paper to make sure of passing the examination for which he had been studying a long while. Mr. Straight, who appeared for the prosecution for the Pharmaceutical Society, said that at first it was thought the prisoner had been acting under the advice of some third person who made it a profession to pass people through such examinations. This, however, had turned out to be not the case. The prisoner—up to that time a most respectable man—had doubtless succumbed to the temptation of making sure of his examination. Under these circumstances, Mr. Straight had advised his clients to ask the magistrate's permission to withdraw from the case; but, at the same time, he wished the public to understand, that should such conduct be repeated, the offender would be prosecuted and brought to conviction and punishment if possible. Mr. Flowers said he quite agreed that this was an exceptional case. He believed himself, that, if the prisoner had had the pluck to go through his examination without trying to cheat he would have passed. Taking into consideration all that had been urged, he should offer no objection to the charge being withdrawn. The prisoner was therefore discharged.

INCREASE OF LUNACY.

AT a recent meeting of the Surrey magistrates, the question of erecting a new building for the accommodation of the increasing number of lunatics was considered. The cost of the building was estimated at £15,000. It was urged that this would not only be desirable on the score of economy, but also on the ground of humanity; and the prospect is held out of affording for the insane both better care and more frequent cures. The Committee of the Brookwood Asylum, in their annual report, adverted to the injustice and impropriety of mixing ex-criminal lunatics with the harmless patients in country asylums, and they invited the attention of the Court to the desirability of representing

to the Government the propriety of making some arrangements whereby the inmates of asylums might be relieved from this hardship. Ultimately, it was resolved to refer the whole question relating to the county lunatics to a Committee.

A SUCCESSFUL BAZAAR.

THE Manchester Children's Hospital Bazaar came to a close on Saturday. The stall presided over by Mr. Bradbury, and given by the proprietors of *Punch*, realised nearly £1,500, 2,500 tickets of half a guinea each being sold for the Book Art Union. Mr. John Tenniel was present, and presided at the Art Union. The expenses will be subscribed for; and £20,000 will go to the charity clear, and a debt of £1,900 be paid in addition.

KING'S COLLEGE HOSPITAL.

ON Wednesday, the 14th instant, the anniversary dinner in aid of the funds of King's College Hospital was held in King's College. His Royal Highness the Duke of Cambridge occupied the chair. There was a large gathering. The usual loyal toasts were given and responded to. In giving the toast of the evening, His Royal Highness said that King's College Hospital was an institution which did an immense amount of good. It was found that the present number of beds (172) was quite inadequate to the real necessities of the hospital; and the Committee were very anxious to increase the number, but were prevented from want of funds. The number of in-patients last year was 1,754, while the out-patients numbered 3,179. There was a large number of out-patients, because the poor patients felt that they could only secure first-rate medical advice by attending at a hospital. The out-patient department, then, could not be regarded as altogether useless. At present, there was no desire to make any change in it; but it was very desirable to increase the accommodation for in-patients. The Committee had had to expend £2,500 lately in much needed repairs and in sanitary improvements. The annual expenditure of the hospital was over £12,000, and of this only £1,600 was from any other source than subscriptions. Donations were good, but variable; and the grant from the Hospital Sunday Fund was only to be regarded as a windfall. It was very desirable, then, that the hospital should receive that support which would not only enable it to continue its present usefulness, but even to enlarge its sphere of utility. The subscriptions during the evening amounted to £1,300.

THE FOOD AND DRUGS BILL.

DR. SEDGWICK SAUNDERS, the Medical Officer of Health for the City of London, has prepared an elaborate report on the Food and Drugs Bill, which has been ordered to be printed and circulated among the members of the Common Council. This Bill he conceived to have been drawn more in the interest of the trader than of the public, the clauses affecting the former for the benefit of the latter being almost nugatory in their application. He thought a standard of purity should be fixed, as well as rules defining the mode of analysis.

UNQUALIFIED GUARDIANS.

KEIGHLEY is unfortunate in suffering at the present time from an epidemic of small-pox; it is remarkable in possessing a board of guardians who, in the face of this epidemic, obstinately refuse to carry out the Vaccination Act by the prosecution of those who neglect to vaccinate their children. Having been threatened by the Local Government Board with a *mandamus* to perform the duties which devolve upon them under that Act, these Guardians seem only to have been filled with the desire to become martyrs to what they regard as a piece of mischievous and obnoxious legislation. The attitude which the Guardians of Keighley have taken up has become so notorious, that for the time being the Antivaccination League have made the town their head-quarters; public meetings have been held, at which the usual mendacious statements have been made as to the general deterioration of health which results from vaccination, and the futility of its effect as a protection from small-pox. The entertainment at these meetings usually includes the edify-

ing spectacle of the burning of the Vaccination Act. In the meantime, small-pox continues to prevail, and the efforts of the Medical Officer of Health, Mr. M. H. Hilles, to stamp out the disease, are to a considerable extent neutralised by the attitude of the Guardians, and the consequent strengthening of the antivaccination party. Mr. Hilles, in a letter to the *Keighley News* of the 3rd instant, publishes some statistics of the present small-pox epidemic in Keighley, which, if facts were appreciated at their proper value, would bring conviction of the value of vaccination even to the mind of an antivaccinator. During the three months ending March 31st last, there were 36 deaths from small-pox in Keighley; only 6 were of vaccinated persons, two having broken-down constitutions; 24 occurred among unvaccinated persons; and 6 were cases of doubtful vaccination. Among those attacked with the disease, the average percentage of deaths to cases during the three months was 4.6 among the vaccinated, 60.6 among the unvaccinated, and 31.9 among the doubtful cases. Only one unvaccinated adult attacked has recovered, whereas the whole of twenty-seven vaccinated adults recovered from the disease. The medical officer points out in his letter the direct mis-statements and garbled statistics bearing upon this epidemic which appear in the antivaccination organ the *Indicator*, which, he says, would scarcely be worth noticing except that they are sure to be reproduced on another occasion by these unscrupulous agitators. The action of the Local Government Board with reference to the Keighley Guardians is anxiously looked for. Is the threatened *mandamus* to end with the threat?

THE TREATMENT OF ANEURISM BY FLEXION.

THE annual report of the Leicester Infirmary for the year 1874 contains some interesting statistics with reference to the administration of anæsthetics. It appears that 208 patients were submitted to their influence; in 199 instances, the agent used was chloroform; in 6, ether; and in 3, chloroform followed by ether. Many of those who were anæsthetised were patients who had met with accidents, and chloroform was used, not only to allay pain, but also for the safer and more perfect reduction and adjustment of dislocations and fractures. In no case was there any untoward result. We also observe the record of a case of popliteal aneurism cured by forcible flexion in six hours and a half—the shortest space of time recorded in a case of this kind to our knowledge. The rapidity of the cure in this instance is, however, almost equalled by a case of popliteal aneurism cured by forcible flexion by M. Verneuil in eleven hours, by sittings of half an hour at a time. The particulars of this case are reported by Mr. Holmes in an article on Verneuil on the Treatment of Aneurism, published in the *London Medical Record* of March 24th.

LARGE DOSES AND POTENT DRUGS.

AT a meeting of the Richmond Academy of Medicine (February 4th), reported in the *Virginia Medical Monthly*, Dr. R. T. Coleman presented the report of the committee appointed to confer with the Committee of the Richmond Pharmaceutical Association relative to the suggestions of the latter Association. The committee recommended (1) that the letters *p. c.* (*præter consuetudinem*) be written by the physician on the left of, and on the same line with, the name of any potent ingredient, when purposely prescribed in doses larger than those ordinarily used; (2) that members of both Societies shall use every proper means to stop the sale of such drugs as opium, chloral, etc., except upon competent medical authority, and that the legislature be memorialised to make proper enactments to effect the object in view; (3) that since the drachm (♥) and ounce (℥) symbols are sometimes fatally confounded because of their strongly marked similarity, when hastily or carelessly written, the Greek capital delta, Δ (the first letter of the word δρᾶμα), be hereafter used instead of the present sign; and (4) that the apothecary is not at liberty to reveal to the patient the components of a physician's prescription written in technical language. Mr. J. Blair, President of the Richmond Pharmaceutical Association, was invited to participate in the discussion. He said that in Germany the physician was required to affix a caution mark opposite the name of any powerful drug prescribed in

unusual doses. The adoption of such a sign would relieve the apothecary of much embarrassment. Dr. M. L. James suggested that the letters be enclosed in brackets, thus [*p. c.*]. On vote, the first recommendation was adopted. The second recommendation was also adopted. Drs. McCaw, Coleman, and Parker were appointed committee to memorialise the Legislature. Regarding the third recommendation, Mr. Blair advocated it as the most important part of the report. He thought that if these suggestions should be adopted by this Society and the Pharmaceutical Association, they would probably be accepted after a time by the National Medical and Pharmaceutical Associations, and thus they might be adopted generally throughout the United States. After some discussion, this recommendation was rejected by a majority vote. The fourth recommendation was concurred in.

SUCCESSFUL RESUSCITATION FROM CHLOROFORM NARCOSIS BY NELATON'S METHOD.

DR. CHARLES WM. COVERNTON, of Simcoe, Ontario, records a case in the *Canada Lancet* of March 1st. Chloroform was administered to a lad aged nine, to facilitate suture of a wound of the hand.

"On asking for a pin to fasten the terminal end of the bandage, Mrs. G., on handing one to me, dropped the sponge; and, to my horror, I discovered there was no evidences of breathing, and no pulse at the temple or wrist. The boy was lying on a sofa, so it was only the work of an instant to place his head on the floor, and direct my son to hold his legs in the perpendicular position. An elder brother, sitting by a window, was directed to throw it open; cold water at hand was dashed on the face, and fortunately without difficulty I was enabled to grasp and keep protruded the tongue with the thumb and finger of my left hand; with my right, I made pressure alternately on the thorax and abdomen, whilst Mrs. G. quietly and intelligently elevated and depressed the arms, settling to the work as coolly as if she had been a member of the staff of the Royal Humane Society for years, neither by word nor sign giving evidence of trepidation. On such alarming emergencies, it is difficult rightly to estimate the lapse of time, but certainly the most wretched quarter of an hour I ever experienced appeared to elapse before there was the least appearance of animation. My son's estimate was over twenty minutes. The first attempt at inspiration was of the feeblest, gradually succeeded by more vigorous ones; vomiting then ensued. In attempting to slightly turn and elevate the head, so as to guard against the vomited matter that filled his mouth regurgitating into the trachea, I lost my hold of the tongue, and the jaws instantly closed like a vice; all attempts at opening them failed, and again I feared the case would prove hopeless. To my inexpressible relief, another faint attempt at vomiting occurred with complete relaxation of the jaws; the tongue was instantly again grasped, and held firm until the breathing was completely established, the pulse was perceptible, and slight coloration of lips and face returned. For another five minutes, he was kept inverted, the nostrils cleared of vomited matter, and friction of the chest with a dry towel employed; he was then replaced on the sofa, made reclining at an acute angle by placing one end on a chair, and in a few minutes we became jubilant. The boy opened his eyes, moved his head to one side, and fell into a calm sleep; this continued for more than an hour, when he awoke conscious. There is little doubt in my mind that, if artificial respiration in the horizontal position had been solely relied on, our efforts would have proved futile."

UNSKILFUL DENTISTRY.

A CHEETHAM dentist was sued at the Salford County Court on the 12th instant by one of his patients, who sought to recover compensation for injuries caused by "the negligent and unskilful extraction of a tooth". After hearing evidence, the judge held that the defendant had not displayed reasonable skill, and awarded the plaintiff £20 damages.

OPIMUM-POISONING IN AN INFANT THROUGH BREAST-MILK.

AN instructive case is recorded by Dr. F. Hawthorn in a recent number of the *New Orleans Medical and Surgical Journal*. On January 7th, a lady, wife of a physician, was operated on, at 12 noon, by Dr. T. G. Richardson. Two hours before the operation, she took twenty-five drops of Battley's sedative solution; at 2 P.M. the same quantity; and at 8 P.M. a grain of opium in pill. Her infant—a healthy boy seven weeks old—was during the whole day restless and fretful, except when imperfectly sleeping. At 12 P.M. he took the breast, and afterwards slept soundly

for six hours, when he awoke and sucked a very little. After this, he continued sound asleep through the day; and at 2 P.M. his breathing was noticed to be somewhat diminished in frequency, shallow, and jerking. At 10 P.M. Dr. Hawthorn saw him, and found the pupils much contracted, the breathing very shallow and jerking, and very irregular, though not much reduced in frequency: he could only be roused with much difficulty. Coffee was given by the mouth and rectum, and he was exposed to the air at the window. He appeared to be much improved at the end of an hour; but an hour afterwards his breathing became arrested for some time, and he was apparently dead. After this he revived, and at 2 o'clock next morning was out of danger. Dr. Hawthorn regards the case as presenting two points of interest: 1, opium-poisoning through the agency of breast-milk; 2, the long duration of the symptoms (twenty-six hours).

THE JEFFERSON MEDICAL COLLEGE, PHILADELPHIA.

The annual commencement of the Jefferson Medical College was held on March 11th, when the degree of Doctor of Medicine was conferred on 170 graduates. Among them was one Englishman, Mr. Charles M. Thompson, who had also the honour of receiving the Toner Medal for "the best Thesis based on original experiments, observations, and researches". The medal was presented by the founder himself, Dr. Toner of Washington. On the same occasion, the Alumni Association presented to the College a portrait of Professor Samuel D. Gross. On making the presentation on behalf of the Association, Dr. W. B. Atkinson recited the more important events of Dr. Gross's career, and paid a high tribute to his personal and professional qualities.

TELEGRAPH WRITERS' CRAMP.

At the meeting of the Paris Société de Biologie on March 20th, M. Onimus stated that he had seen two cases of an affection analogous to writers' cramp, and which is not uncommon in telegraph clerks, especially those who use Morse's instrument. They themselves call it the telegraphic complaint, and it may henceforth be designated as telegraph clerks' cramp. The affection begins by some stiffness in the manipulation of letters in which the strokes and dots are disposed in a certain way. By degrees, all manipulation becomes impossible; the patient then tries to make use of the thumb, then of the wrist; but movement becomes impossible, and is accompanied by incoordinate motions. The best means of avoiding this affection is to change the instrument, and to replace the Morse telegraph by Hughes's. In England the malady is said to be unknown.

SCOTLAND.

A CONSIDERABLE number of cases of fever, chiefly typhus and typhoid, are stated to exist in Greenock. The authorities are taking precautionary steps to prevent the spread of the disease.

THE Bazaar at Glasgow for the Hospital for Incurables, realised altogether, after being open for seven days, the sum of £13,900; and as £14,000 had been subscribed previous to the bazaar, the total sum available will be close on £28,000.

MR. JAMES DEWAR, demonstrator of Chemistry in the University of Edinburgh, and formerly assistant to Professors Tait and Lyon Playfair, elected to the Jacksonian Professorship of Chemistry at Cambridge.

ALTHOUGH much has been done for the purification of the North Esk, the impurities which find their way into the stream are still considerable. Some time ago a plan was suggested by Mr. H. Stewart, C.E., for thoroughly preserving the river from pollution, by conveying the refuse from the paper-mills in a large pipe, which would be laid in the valley of the Esk, and be connected with all the mills, and would discharge into the sea near Musselburgh. Another plan which has been mooted is the precipitation process, which has been tried with

some success in one large mill at Lasswade. Messrs. Hawksley, C.E., and Leslie, C.E., and Dr. Falconer King, chemist, Edinburgh, have been appointed, by the parties interested, to survey the Esk, and report on the feasibility of Mr. Stewart's scheme from the engineering and chemical point of view. Supposing the engineering difficulty of laying the pipe to the sea to be solved, it will require to be determined whether the effluent waters, with their impurities, will not corrode ordinary pipes. The investigation is likely to last some time.

THE BLIND IN EDINBURGH.

FOR some time past, a project has been on foot for the amalgamation of the Gayfield Square School for Blind Children with the Edinburgh Blind Asylum. A formal agreement has been at length drawn up, and the arrangement will take effect as soon as the buildings in progress can be completed. The Gayfield Square institution has been engaged in educating blind children for the past forty years, and now musters thirty-four inmates and six day scholars. There has been no falling off in the number of applicants during the past two years, as it was expected there would be, now that the School Boards are chargeable with the education of the blind; and it has long been evident to the directors that it is desirable to afford the pupils some industrial training in addition to the purely educational help previously given, in order to fit them for gaining admission, at the age of fifteen, to the Blind Asylum. With this view, and with the prospect of a saving in working expenses, an arrangement has at length been come to, by which the asylum directors take over the thirty-four children at present boarded on the school premises, at the same time acquiring such property and funds as the directors of the school have at their disposal. In order to provide accommodation for the new inmates, the asylum managers have commenced building the remaining wing of their house at West Craigmillar, a portion of the work which had for the time been left in abeyance. It is expected that the new asylum, which is to cost about £15,000, will be completed in the course of the present season, and that, at the beginning of next year, the female blind, at present in a house in Nicholson Street, and the school children, will be removed thither. In connection with this change, it is intended to devote increased attention in the asylum to musical education, as it is thought that, when there are children to deal with, special musical aptitude will be earlier discovered, and means can then be taken to give them such a musical training as will enable them, as tuners or organists, to earn a comfortable livelihood.

THE EDINBURGH DEAF AND DUMB INSTITUTION.

THE annual meeting of the subscribers of the Edinburgh Deaf and Dumb Institution took place last week in the schoolroom of the institution. From the sixty-fifth annual report, it appeared that, during the past twelve months, 13 pupils had left and 10 had been admitted, and that the number at present in the institution was 56, being 4 less than at the same time last year. Of these, 33 were boys and 23 girls. The report further stated, with regard to the health of the pupils, that in the month of December there had been five cases of scarlet fever, and during the year there had been one death from obstruction of the windpipe; but, at present, all the pupils were in excellent health. It was also reported, that the following legacies have been received during the past year: £1,000 from Mr. Grindlay, £289:9:6 from Mr. D. Nisbet, £100 from Mr. Dewar, and other smaller sums. The progress made by the deaf-mutes in all branches of knowledge in which it was possible to instruct them was very satisfactory.

PHYSIOLOGICAL ACTION OF LIGHT.

At the last meeting of the Royal Society of Edinburgh, Mr. James Dewar read the second part of a paper by Dr. McKendrick and himself "On the Physiological Action of Light". In this communication were detailed the physiological effects of various coloured rays, namely, those of the solar spectrum, and those produced by polarised light, the result being that the electrical effect registered by the galvanometer was

greatest for the rays which appear to us most luminous. Experiments on the relation of the brain to electrical action also showed that the current was sometimes greater and sometimes less than that of the normal nerve. Experiments made with the view to determine the electro-motive force, by a very exact method, were described, and lastly there were given the results obtained in the registration of minute intervals of time, which showed that the production of luminous impressions required, in the case of the eye of the frog, 310 of a second. The apparatus employed in conducting these experiments Mr. Dewar characterised as new, and of a very delicate and refined nature. In the course of the evening, Professor Kelland, who was in the chair, introduced Captain Nares, late of the Challenger Expedition, and now chief of the Arctic expedition. The captain said that the richest stores of the Challenger expedition were the deep sea fisheries; and from the seas lying above clay bottoms they had got two or three hundred new species, many of which must be identical with geological specimens.

THE RAINFALL.

THE rainfall during March was very much below the average, except the east and south-east of Scotland. In these regions, the general deficit is marked by a heavy fall during the night of the 8th, accompanied by south-westerly gales. Over the remainder of the kingdom, the continuance of dry northerly and easterly winds has been very remarkable, and, as a result, we find that on our south-western coasts only about one-third of the average fall has been recorded, while in the south-east of England a still smaller proportion has been measured.

IRELAND.

A CONVERSAZIONE was held at the Royal College of Surgeons of Ireland, on Thursday the 15th instant.

DURING the first quarter of the year, the births registered in Dublin amounted to 2,404, and the deaths to 2,700; being an increase in the births of 316, and of 562 in the deaths, over that of the preceding quarter.

ELFELT LYING-IN HOSPITAL.

THE annual report of this most admirable institution has been issued, and from it we find that, during the past year, the number of patients admitted was 174; and that there were 175 births, one case of twins, and eleven still born, whilst, out of the 174 admitted, but two died. The report draws attention to an important point in connection with the hospital, namely, that nurses are admitted in succession for training, on payment of a fee, and allowed to remain for six months' residence in the institution.

THE LATE DR. JAMES SAWYER.

THIS gentleman, who was formerly Professor of Midwifery in the Royal College of Surgeons, but lately resigned in consequence of ill-health, died at his residence near Dublin, on the 12th instant. He was one of the Masters of the Coombe Lying-in Hospital, Dublin, and had formerly a considerable midwifery practice.

MEATH HOSPITAL, DUBLIN.

AT a meeting of the standing committee of this hospital held on Monday, the 12th instant, it was unanimously resolved: "That this committee, having heard of the resignation of Dr. Stokes, desire to place on record an expression of their sense of the inestimable benefits conferred by him on the hospital during his long service in it, and of their regret at the severance of his official connection with it."

STIMULANTS IN WORKHOUSES.

DURING the year ending March last, there were consumed in the Cork Workhouse, 726 gallons of wine, 219 gallons of whiskey, 4,766 gallons of porter, and 212 bottles of brandy, at a cost of £685 15s. 7d. The number of inmates on Saturday, March 27th, was 2,231, of whom 1,058

were "patients", and the return of stimulants for that period that they consumed was 1,046 glasses of wine, 411 of whiskey, and 705½ pints of porter, whilst the supply of meat was 2,078 lbs., and of eggs 1,990! Comment is superfluous; but it may be said that although this state of things may make the inmates very comfortable, it must be excessively disagreeable for the ratepayers.

ASSOCIATION INTELLIGENCE.

SOUTH HANTS DISTRICT: SOUTHERN BRANCH.

THE next ordinary meeting will be held at the Red Lion Hotel, Fareham, on Tuesday, April 20th, at 4.45 P.M.

Notice has been received of the following communications:

1. Dr. MANLEY: The Diagnosis of Insanity.

2. Mr. G. H. CASE: A Case of Polypus of the Rectum.

Dinner will be provided at 6.15 P.M., charge 6s., exclusive of wine. Members intending to be present, are requested to communicate with Dr. Case, Fareham, on or before April 17th.

J. WARD COUSINS, *Hon. Sec.*

NORTH OF ENGLAND BRANCH.

THE Spring Meeting of the above Branch will be held at the Assembly Rooms, Bath Terrace, Tynemouth, on Thursday, April 29th, at two P.M. The following papers have been promised:

1. On the Treatment of Habitual Drunkards. By Dr. Eastwood.

2. On the Pathology of Catarrhal Pneumonia. By Dr. Macdonald.

3. A case of Extrauterine Fœtation. By Dr. Byrom Bramwell.

4. A case of Extrauterine Fœtation. By James Wilson, Esq.

5. A case of supposed Renal Calculus. By Anthony Bell, Esq.

Gentlemen who are desirous of reading papers, exhibiting pathological specimens, or making other communications, are requested to communicate with the secretary, at their earliest convenience. Dinner at the Bath Hotel, Tynemouth, at four P.M. Tickets, 7s. 6d., exclusive of wine.

G. H. PHILLIPSON, M.D., *Honorary Secretary*.
Newcastle-upon-Tyne, April 3rd, 1875.

MIDLAND BRANCH.

A QUARTERLY meeting will be held at Lincoln on Wednesday, May 5th. Members desirous of reading papers are requested to communicate at once with

C. HARRISON, M.D., *Hon. Sec.*

Lincoln, April 11th, 1875.

BORDER COUNTIES BRANCH.

THE spring meeting of the Branch will be held at Carlisle on May 12th 1875. President, Dr. Green, Kendal; President-elect, Dr. W. A. F. Browne, Dumfries. Gentlemen intending to read papers, or be present at the dinner, are requested to give notice to the Secretaries.

HENRY BARNES, M.D. } *Hon.*

J. SMITH, M.D. } *Secs.*

Carlisle, April 13th, 1875.

PRESENTATION.—The staff of the British Equitable Assurance Company on the 9th instant presented to Mr. Thomas Carr Jackson, M.R.C.S., a valuable service of plate, in recognition of twenty years of professional service. The managing director of the Company (W. S. Gover, Esq.), in making the presentation, stated that Mr. Jackson had been professionally connected with the Company from its commencement, and that it would be difficult to overestimate his great industry and incredible painstaking. His labours had been submitted to the most severe tests with uniformly satisfactory results; and it only remained for him (Mr. Gover) to present the testimonial, and express an earnest wish that the happiness, usefulness, and valuable services of Mr. Jackson might be long continued. Mr. Jackson thanked the meeting.

TESTIMONIAL.—In recognition of the services of Mr. A. G. Roper of Croydon, in behalf of the Croydon General Hospital, to which institute Mr. Roper is the Honorary Secretary, a number of the inhabitants subscribed to a testimonial, which took the form of a rosewood oblique grand pianoforte, with music cabinet, a silver tea- and coffee-service, with tray and salver, a handsome drawing-room clock, and vases to match. The salver contained the following inscription. "This salver, with a tea- and coffee-service and tray, was presented to A. G. Roper, Esq., F.R.C.S., by the friends of the Croydon General Hospital, in acknowledgment of invaluable services rendered by him as Honorary Secretary to that institution. March 11th, 1875."

REPORTS OF SOCIETIES.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, APRIL 7TH, 1875.

W. O. PRIESTLEY, M.D., F.R.C.P., President, in the Chair.

ON THE RELATION OF PUERPERAL FEVER TO THE INFECTIVE DISEASES AND PYÆMIA.

At a very full meeting of the Society, Mr. SPENCER WELLS opened the discussion previously announced by an Address, which will be found printed at page 501.

Dr. LEISHMAN (Glasgow): In availing myself of the opportunity which the courteous invitation has permitted to me of taking part in this discussion—for I presume there can be little doubt that the remarks of to-night will more or less take the form of a discussion—I am a little taken aback in your having selected me as the first speaker after the distinguished essayist of this evening. I confess, however, that I have a peculiar satisfaction in being able to speak to-night on this subject. I may say I have in some measure a personal satisfaction in speaking, upon various grounds. I think I shall have the support and sympathy of every person present whose duty it has been to teach the subject of obstetrics, and still more, perhaps, I may have the support of those who have had occasion to write upon this particular department of obstetrics, when I say that, when in their lectures they approach the subject of puerperal fever, they have felt that they were approaching a subject with which they were in a great measure incompetent to deal. It is not for me to explain, nor would I presume for a moment to indicate, the reasons of this in all their bearings; but I can well understand, and from experience I can assert, that the difference of opinion which has at all times existed on this subject has been the main reason of this confusion. I have a strong personal feeling in regard to this subject, because I have, to some limited extent, disseminated views which I now feel to have been erroneous; and I am, therefore, glad to have this opportunity, before such a distinguished body of my fellow practitioners, of disclaiming, and in a sense abjuring, certain errors which I have had some share in disseminating among the juniors of the profession. I have regretted every day since I wrote on the subject that I had not more thoroughly investigated the evidence of the pyæmic source of puerperal fever; for the more I have done so, the more convinced have I become that, in a large proportion at all events of these cases, there is strong evidence to lead us to believe that they have their origin in pyæmic or septicæmic infection. I am not prepared to go the length which I believe many writers in Germany and some in this country have gone, in supposing that we are permitted to accept this pyæmic theory as the solution of all our difficulties; that by admitting pyæmia, or septicæmia, or ichorrhæmia, or whatever you choose to call it, as the cause of puerperal fever, we get rid of all our difficulties; and that for what we have hitherto considered *chaos*, we may in future read *cosmos*. I do not believe that it is so; for there are points of difficulty which must arise in the mind of every man of experience which have yet to be solved. I admit, and I should like to admit with all possible emphasis on an occasion like the present, that I believe the pyæmic or septicæmic origin of many cases of puerperal fever has been fully and thoroughly established; but I am not at all sure that this will account for all the cases that come before us in practice. There are cases in which a patient in the puerperal state unfortunately becomes the subject of diseases of specific origin. I may mention as an illustration scarlatina. A patient becomes infected with the specific poison of scarlatina. There is nothing in practice which we dread so much, and the result unfortunately proves that our dread is well founded. But, in the later history of such cases, I have had a difficulty in discovering any difference between the cases which we may suppose to have a specific origin and those which have proceeded from a specific poison. Again, there is another class of cases in which it would appear as if the original symptoms were more those of a local inflammation, be it metritis or peritonitis, localised or general; and in all these instances, whatever the initiatory symptoms may have been, in so far as my experience enables me to form an opinion, I have again a difficulty in separating those cases, as far as the final symptoms are concerned, from those in which puerperal fever is dependent on pyæmia or septicæmia. These I take the liberty of presenting to the Society merely as the difficulties which have suggested themselves to my mind, having naturally, and as a matter of necessity, had the subject under consideration for a long time. I well know that in what I have written on the subject I have stated views which I am not prepared to support; I therefore began by frankly withdrawing something of what I had previously written; and perhaps what I now state may enable those

members of the Society, if there be any such, who have done me the honour of perusing what I have published, to correct these views. There are other points which suggest difficulties. We have frequently been informed that these diseases are likely to be engendered by decomposing animal matters, from whatever source the decomposition may originally arise. It has been very commonly asserted, and rules in fact have been framed, bearing upon the question in those countries more particularly in which puerperal fever is most common, that students who dissect are liable to convey this infection. I have not the slightest idea of calling in question the accuracy of this assertion; but what I should like to point out is this, that if this were so certain and so frequent a method of communicating the disease as some would suppose, we should have far more puerperal fever in the practice of students who dissect. Then, again, if we are to assume this question of pyæmia as identical with puerperal fever, we know what pyæmia is in a surgical hospital. I presume it was the prevalence of pyæmia in surgical hospitals which led the late Sir James Simpson to write his celebrated papers on hospitals. Pyæmia in a surgical hospital is a dreadful scourge. It may be conveyed by the surgeon; it may be conveyed by dressers, by nurses, by anybody; and beyond a doubt it may be conveyed, as Professor Lister has clearly shown, through the atmosphere. I consider that that is a point which now-a-days is demonstrated. Yet in surgical hospitals, pyæmia is not such a scourge as puerperal fever is in lying-in hospitals. If you have the disease once existing in a lying-in hospital, you have it communicated with a frequency, with a fearful fatality in point of result, which it is appalling to contemplate; so much so, indeed, that I think I scarcely exaggerate matters when I say that, in some continental towns, the condition of a woman entering a lying-in hospital for attendance and care during the puerperal period, is something like this: that she must be content to incur the risk of a patient who takes typhus fever in the discharge of this purely physiological function. Now, this identity of pyæmia and septicæmia with puerperal fever may be established within certain limits, or it may not; but it appears to me that there is an intensity in the infection, that there is a peculiarity in the conditions, or there may be (as has often been said) in the woman in the puerperal state, a peculiar condition, which renders her specially liable to impressions about which we know very little, that may account for all this. These are points which, in connection with those that have been formulated so kindly and ably for us by Mr. Spencer Wells, it appears to me should be taken under the consideration of the Society. I am unwilling to take up the time of the Society longer. There are many points on which I should like to speak; but I should be sorry to carry the forbearance of the Society even to the limits in point of time which you have laid down. I cannot, however, sit down without congratulating the Society as a body on the fact that this important subject, perhaps one of the most important of the present day, has been in this prominent manner brought under the notice of the Society, in the temperate and dispassionate manner that it has been to-night, rather inviting discussion than stating broad and distinct views with which we must agree, or from which we must be prepared absolutely to dissent. And I would almost venture to predict that the result of the discussion which has been inaugurated to-night, arguing from the interest which it seems to have awakened in all quarters, will be a result which will be for good, for abiding good, in the future history of obstetrics.

DR. NEWMAN (Stamford): In rising to speak, I may say that I meet the requirements of your courteous invitation in two respects. I am a country practitioner, and I have come from some distance—I cannot say with the express object of being present to-night—but, at all events, I am glad that the opportunity should offer itself to me of listening to the discussion this evening, on a subject of so much importance to us all. You will pardon me if, in speaking on the matter, I may seem to speak too egotistically. I simply say that, after some twenty years of tolerably hard country work, first in a village, then in a country town, in general practice and hospital practice, I have come to certain conclusions which may or may not be correct, and which I should have a difficulty in following out one by one, giving you the arguments that have brought me to those conclusions. In taking the propositions which Mr. Spencer Wells has formulated for us this evening, I may say, in the first instance, that I should hold strongly that there is no such thing as a definite puerperal fever, so called. In the next place, I should say, with equal decision, that in a large number of cases of puerperal fever—I have traced it in my own personal experience, and have known it in the practice of other gentlemen with whom I happen to have been associated—there has been a distant, it may be yet a definite, link in the occurrence of possible transmission to the patient of some definite infecting poison. I cannot give a much more striking instance of it than this. Some years ago, I saw a lady who was exceedingly ill with puerperal fever. Two days after my visit, she died. The opportunity was afforded me of close inquiry, I might almost say

exhaustive inquiry, into the history of the few days or few weeks that preceded her delivery. It turned out that there had been a visit paid by her to the house of a neighbour in the same village, and a child in the house was at that moment suffering from scarlet fever. She knew nothing of it; she simply knew that the child was ill. She paid no attention to it, and, until the inquiry was pushed as closely as it could be, there had been no idea in the mind of the patient, or in the mind of the medical attendant (for he came from a distance), or of any one connected with her, that that could have been the cause of the disease that led to the fatal issue. I should take that simply as a type, and say that my impression is that, in a large number of instances, of some of which I have notes, and of some none, the condition in question has its origin in direct or indirect communication with some infective process. There is another set of cases—and I am again drawing on my memory for a very clear one that I happen to have seen—where I believe that a local inflammatory mischief may unquestionably kill, by its production of a definite pyæmic condition, as certainly as it would kill in the instance of a surgical operation followed by pyæmia. I was asked some time ago to see a woman, who had been suffering for two months. She was supposed to have been three or four or five months pregnant, and she had been suffering for two months from a certain amount of hæmorrhage. She had lost so much blood, and her general condition was so bad, that one felt that the only thing to offer her a reasonable chance was at once to empty the uterus. This was done by her own attendant at my suggestion, in the first instance by the dilatation of the os uteri, then by manual removal of the fetus or ovum, and the secundines. Within three days, she had rigor; and when I saw her subsequently she had all the symptoms of pyæmia. She had an abscess in the shoulder-joint, an abscess in the wrist, and not a few collections of matter in different portions of the body. That again I should take as a type of another set of cases, where I believe a morbid process, which we are satisfied to call puerperal fever for want of a better term, had its origin in a direct local lesion. That lesion may have been produced by enforced dilatation, and the forcible removal of the retained material; but still there the condition was. I have further to say—and here I am referring to what has fallen from the preceding speaker—that one has very much to bear in mind that even in our present state, with fairly careful houses and the rest, there is not uncommonly such a condition of sewer-air permeating the houses, that the general state of a parturient woman before her delivery is below par; hence the greater tendency on her part to absorb—if I may use the word—infective material, however it may be presented to her. I would further add that there can be very little question that the activity of the vital processes would certainly seem to be associated from the very earliest condition of pregnancy to its close,—that the history of every pregnant woman must be understood by a no far-fetched analogy, to have a material influence upon the question before us. Given a woman in whom all the processes, nervous, vital, circulatory, mental, if you like, are materially excited or altered in their condition of reasonable health; and I should maintain that in that phase alone we have much to look for in the way of an explanation of the reasons why poisons that run a different course, or at all events a slower course, under more ordinary states of everyday life, run, when they have to deal with a parturient woman, a course of far more severity and far greater rapidity, and, unhappily, far greater fatality. One more remark, and I have done. It seems that one should take into consideration, at all events that one should not hastily dismiss, the mental conditions which not uncommonly associate themselves with pregnancy. On this ground it happened to me some years ago to tabulate—I never did anything more than tabulate—a certain number of cases of puerperal fever that had occurred to my own knowledge. I think I may say that in a good number of them there were, at all events, the elements of distinct mental disturbance. I do not refer to mental disturbance in the sense of insanity, but in the sense of distressing circumstances, of the condition of pregnancy being a result of seduction, and many other reasons which will occur to gentlemen present. These do unquestionably seem to me to play a material part, at all events, in predisposing the system to the virulent development of septic poisons, however they happen to be introduced. I have to apologise to the Society for the very imperfect manner in which I have spoken. I began by saying that I would simply give my own personal impressions. I ask the Fellows to be good enough to accept them, and to give to them the very small value that they actually possess. I had no intention, when I thought of coming to the Society, to join in any way in the discussion; and I may almost say that, if I had not had a direct personal invitation, I should hardly have dared to do so.

DR. BRAXTON HICKS: I presume that by the discussion in which we are engaged we shall not be able to clear up all the ambiguities and uncertainties with which this subject is surrounded. I take it that the

principal advantage of such meetings is that the current opinion of observers may be brought out, and thus a certain impetus is given to the progress of knowledge, which would not have taken place, had each speaker waited to mature his opinions. Hence it follows that opinions expressed under such circumstances have more or less the disadvantage of imperfection, though it may be that the hints thrown out by the various speakers will stimulate thought in others, and, indeed, in themselves. The difficulties of this subject have been somewhat retarded by two means. First, most of the older observations were made in hospitals, and thus, if we admit that the disease is contagious, the character of the cases in each epidemic is similar. Thus, some have said puerperal fever was erysipelas, diphtheria, etc. Another retardation arose from the very means by which information was obtained; namely, from the *post mortem* room. For, according as one appearance was more prominent, so it was considered the essence of the complaint; thus peritonitis, enteritis, phlebitis, etc., were considered the real disease, instead of being looked to as effects. Not that I would underrate the value of these investigations, carried on as they were at much personal risk, but to point out that these opinions prevented the observer from looking in the real direction, namely, to the clinical facts, derived not only from hospital, but from all the variable conditions of home attendance. However, the general *post mortem* appearances having now been ascertained and well known, it is to the clinical study of the disease that I would now urge the attention of obstetricians, leaving the inquiry as the exact nature of the poison as a separate one, simultaneously carried on, but still separately. By this means we shall proceed with more distinctness of purpose. I have already, in a paper called a "Contribution to the Knowledge of Puerperal Diseases", endeavoured to show the clinical aspect of the conditions classed under the general head of "Puerperal Fever", taken from the various circumstances of home attendance in all classes of the community. I would not again detain the attention of this Society, by alluding to the facts there shown, did I not consider them to have a great bearing on the subject of the paper of this evening, and that from further inquiries, the results there set forth may be taken as a fair average of practice as seen in consulting practice. There is no doubt that they represent the severer cases; but I must here point out an error into which many fall in estimating the extent of the influence of circumstances on the puerperal woman by the death-rate. It is not by the death-rate we can judge; I should say, broadly, that where one dies, three or more are retarded in their recovery by either a more or less mild state of fever, or by the secondary effects well known to us as cellulitis, phlegmasia, etc. Not till these also are calculated, can we recognise fully any influence brought to bear on the puerperal woman. Now, the cases brought forward in that paper were those of simple labour; I did not include any about which I had made no inquiry as to the surroundings, either those which existed before or after. I found that, out of 89, 68 had been connected in some kind or another with animal poisons, more than three-fourths. Of these 68, more than half, namely 37, had been connected with scarlatina in one way or another. Amongst the remainder, erysipelas, diphtheria, and offensive state of the discharges were prominent; in the remaining 21 I could trace no definite history in regard to zymotic diseases; but it would be difficult to say how many might not have been influenced by them, seeing it is hard to tell in many cases of zymotic diseases whence the source of infection had come. Some undoubtedly had been exposed to mental depression or excitement, were in low condition of health, or otherwise in conditions not favourable to recovery from any great disturbance. But of the first class it may be asked, Are these really cases of puerperal fever? Are they not properly cases of puerperal scarlatina, diphtheria, erysipelas, and so on? Let us, then, for the moment exclude them; though in doing so we are excluding three-fourths of what have been received as cases of puerperal fever; at any rate, with the exception of the well marked scarlatina cases. Let us examine the remaining 21. Shall we exclude or include those of them which have been brought on by sudden mental disturbances, as fright, annoyance, and anxiety? They probably amount to a fourth. If we exclude them, we shall be excluding cases like those which have been called "puerperal fever"; and yet, unless these influences generate the fever, we must exclude them. Again, four of the 15 left were ill before labour set in, and these can scarcely be looked upon as cases of puerperal fever. Some of the yet remaining 11 possibly may have had an influence from a zymotic disease, as I have already hinted. Some were of traumatic origin, not toxicemic; and, allowing three for these, we reduce the total of unexplained origin to eight. Now, I would ask, Where is the proof of the existence of a separate entity such as is ordinarily understood by puerperal fever? and close upon this result, I maintain, will be arrived at if you take any hundred of cases. But when you come to examine the symptoms belonging to the various classes, you will find that they all belong to the same class; and if you,

as I did for a moment, exclude those cases influenced by zymotic diseases, you are met by this difficulty: that those without any specific symptom, as rash, etc., showed symptoms most typical of the so-called puerperal fever; that the specific symptoms were in all grades of proportions in the several cases; and that, generally speaking, the less the specific signs showed themselves, the more tendency there was to malignancy. This fact is well shown in hospitals where, erysipelas being the primary cause, the disease which followed would be more like to malignant puerperal fever, and less like erysipelas. In the paper alluded to, many cases may be found showing this. I may venture to repeat one. A woman was taken with the most malignant form of puerperal fever, and died about the third day. I could find no history of scarlet fever previously; but, in a few days, two of her children had malignant scarlet fever and died. Since my paper, I saw the following case: a lady had been delivered twelve hours, when feverish symptoms commenced; a pile already inflamed became very tender and painful; from this part a bluish spread, something like erythema, but without any defined edge, and spread over her back. About the third day, arthritic pains and swelling commenced, with delirium; these symptoms increased in intensity, and she died in great agony on the fifth day. As the symptoms began so soon after delivery, I could not help suspecting that it had its origin from without, as the symptoms arising from decomposing secretions commence from the third to the fifth day. I could not find that she had been exposed to any exanthem. The medical man had not seen a case for two or three months. The nurse was apparently free. I, however, told the medical man I thought he would have evidence in the children. In about a week, the eldest child had scarlet fever, and rapidly died. The second was then attacked, and shortly died. Subsequently the baby was attacked, but recovered. In neither case was there any specific sign of scarlatina. Numerous cases I have seen where scarlatina was in the house, and the mother had puerperal fever without any rash. In some of the other cases where there are signs of a zymotic disease, yet they would have been overlooked had not care been taken, so masked were they by the general condition. But some have rejoined, "I have attended cases of scarlatina and delivered women constantly, and that without ill results". I would answer, Even so. But this is no proof that the influence of scarlatina is not detrimental. It is not every woman that is exposed to scarlatina who contracts it; on the contrary, most have already had it, and thus are less liable to catch it. It would be but few married women who would be susceptible to it. It would be an interesting point to know whether those are seriously affected by scarlatina who have had it in former years. I have not sufficient information as yet. But, as I have said before, the death-rate must not be the criterion of influence. We must watch the patient for a month. It is seldom but what we shall find a bad getting-up in one who has been exposed to scarlatina just before or during her labour. An apparent contradiction to the influence of scarlatina has been instanced by the fact that sometimes, during an epidemic of scarlatina in a town, the lying-in hospital is free from puerperal fever. This is no proof. The only proof reliable is to be able to say that frequently cases of scarlatina have been introduced into lying-in wards, and no ill effect followed. The same answer applies to erysipelas. But there is another point which cannot be left out of consideration, viz., that violent mental emotions also are followed by symptoms precisely similar to those which follow zymotic influence, or the existence of putrid discharges. In fact, looking over the whole cases, we are, at least at present, unable to distinguish as a class the one from the other, excepting where the specific symptoms are superadded. To what conclusions, therefore, are we led? In some cases, no doubt, some other medium must be added, such as decomposing "sepsis", or the living bacteria, or some material which, mixing with the discharges in the uterine cavity, are absorbed into the system. It is difficult, in our present state of knowledge, to assign the proper value of this influence. That decomposing matter does cause these symptoms can readily be proved, but whether it acts through living or decomposing material, there is no evidence sufficient to permit us to argue. One thing seems to militate against the notion that it is the bacteria which, in many cases, accompany the absorption of offensive discharges; namely, that if we wash out the uterus, the symptoms very rapidly subside; in twenty-four hours I have seen them pass mainly off. If living growths were going on, one would scarcely expect so rapid a subsidence. Whatever may be the exact nature of the poison, in our present knowledge I do not consider we are justified in basing any line of practice upon it; certainly not in allowing our clinical inquiries to receive any bias. That the puerperal woman is, by means of these various factors, brought into a state which we recognise as blood deterioration or disturbance, so that either she dies rapidly, or that, if this event be postponed, the processes required for repair after labour are so perverted as to be accompanied by inflammation extending to the peritoneum, or producing

effusions which often tend to suppuration; or to the uterine veins, producing plastic plugging and its consequences; or the blood assumes a tendency to coagulate, and thus fibrinous deposits form in the vessels; in fact, to all the secondary troubles well known to us all, as the results of the primary blood disturbance, but considered formerly as the principal condition. Such is the liability of the puerperal woman to these deteriorating influences, that I think we may generally trace nearly every ill getting-up to some depressing or disturbing influence, if we take the trouble to trace it. Whether the blood-conditions set up in the puerperal woman are similar to the so-called pyæmia, such as is observed in men and non-pregnant women, is not quite certain. That they seem to differ rather in intensity than in quality, I think is generally admitted. We can readily understand the intensification when we consider the altered condition of the blood in pregnant women, and the ease with which the nervous system is perturbed; intensified by the large surface which is exposed, and the greater facilities for absorption which exist in the anatomy of the uterus, compared with the conditions found in the male. The position of the question appears to me this: admitting that various circumstances can set up a malignant fever in the puerperal woman, has this fever so set up a permanent character capable of being communicated to other pregnant women? Looking to the cases as they occur in hospitals, there seems some reason to think there may be such a condition. Looking to private practice, one would also say so too, did we not see that apparently, when it spread to non-puerperal persons, it became reconverted to the zymotic form from which it had sprung. No doubt many difficulties attend this point of the inquiry; and to it attention should be particularly directed. However, without going so far as this, one may fairly say that a zymotic disease, if not modified in its true nature, is altered as to the usual character of the symptoms, assuming more the kind which have been generally called "malignant" in the non-puerperal person; and this tendency to change its character is more noticeable the nearer the patient has approached the full term of pregnancy; whether this depends on the changed condition of the system, or the greater patency of the lymph spaces and veins, so as to increase the quantity absorbed, is not very clear. Seeing the many sources of contagion that surround all of us, I think that the notion that the aggregation of a number of puerperal cases can set up, *ab initio*, a puerperal fever has no resting place. The aggregation unquestionably increases the number of chances of the introduction of some zymotic disease, while the exposure of a number to the disease will necessarily increase the number of persons affected. All aggregations do this. The same rule applies to surgical wards, with regard to erysipelas. While, therefore, I agree that aggregation tends to spread the disease, I am doubtful whether it sets it up, if cleanliness be carried out properly. But when once an exanthem has been introduced, then its eradication is by no means easy; and the constant recurrence of cases, without complete purification, may fairly, to my mind, justify many of the remarks on what was called, perhaps not quite correctly, "Hospitalism". There is only one other point to which I wish to allude: this is respecting the contagious nature of the conditions grouped together as puerperal fever. That the majority are contagious to puerperal women I have no doubt; whether all are so, I am uncertain. I am inclined to think that those forms derived from the zymotic diseases are the most so; those from the self-generated kinds the least so. Some few seem not at all contagious. I remember two students attending a woman with puerperal fever for some days; during this time, they attended some twenty cases of midwifery. None of these were ill afterwards. A second instance occurred. Before the nature of the case had been made out, upwards of twenty were attended without ill result. However, I wish I could say this of all. I have had lists not unfrequently given me by practitioners, where the effects from a smaller series were very differently shown, and yet I saw, a short time since, a most malignant form coming on apparently from mental distress. A coachman's wife, just after labour, heard that her husband had to leave his place. She was much affected, became violently maniacal for a few hours, and then subsided into the usual condition of malignant puerperal fever, of which she died in a few days. The medical man attending her told me he had to attend another in a day or two afterwards, and she died in a rapid manner. But, surrounded as we all are by contagium, it is very difficult to say how far any case is free from zymotic influence.

MR. JONATHAN HUTCHINSON: I, of course, have nothing to do with obstetrics, or with puerperal fever, but I believe that the subject is one which has its analogies in general surgical practice, and one of the most interesting points in Mr. Spencer Wells's address was the manner in which he traced that analogy. If I correctly understood his views, he seemed to place puerperal fever almost exactly in the position in which we place the several kinds of maladies from which our patients suffer after operations. He would say that there is no such thing as a specific poison which can produce any fever that should be

known as "puerperal fever," but that a number of maladies induced by various causes have been grouped together under that name, and I thought that he very ably classified these according to the several causes which produced them. I hope the time will come when he will extend his unwillingness to use such a vague term as "puerperal fever" to a term which, I think, he accidentally used—"surgical fever". For, if puerperal fever be absurd, I contend that surgical fever still more leads us aside from the consideration of the true causes of the malady. If I may be permitted, I should like to say a few words on the great importance of attempting to define as precisely as we can the terms we use. I think we should much more easily get to conclusions, and find a much greater unanimity of opinion, if we did take these several terms, septicæmia, erysipelas, specific disease, specific fevers, and try to attach to them some definite meanings. Although it may seem presumptuous, I will state what my own opinions upon these subjects are, with great deference to the Society, and hoping to hear my views criticised and set right, if they seem to be erroneous. I will say, with regard to erysipelas, that it is a disease which is of great importance in reference to puerperal fever, since we have the most of proof concerning it that the contagion from it is one which is potent in the induction of the local inflammation, which produces puerperal fever. I express, in the most unqualified terms, my belief that erysipelas is not a specific fever, that it is only a local form of inflammation, that this local form of inflammation may vary in intensity, may vary in duration, may be induced by many different causes, may undoubtedly be produced by contagion from the secretions of an erysipelatous patient, but may also be produced by other causes; and that the pyrexial symptoms and general disturbance are secondary to the local inflammation, and are proportionate to the local erysipelatous action that exists. I have expressed this opinion on many occasions. It is the opinion, I believe, originally stated by Mr. Higginbottom of Nottingham, and I regret that the majority of our systematic works still, without defending the position of erysipelas to rank as a specific disease, still so define it. Authorities still assert respecting it, that it has a stage of incubation, and this I wish definitely to deny. It has a stage of development; certainly there is, it is true, a day or two during which the patient may be ill before the redness appears; the disease wants a little time to develop, but there is no true stage of incubation. When we know that it arises from contagion it will develop in a day or two of the virus being applied, within twenty-four hours, and that is fatal to its claim to rank as a disease due to a specific poison. Then we never see it prevail symmetrically in the two halves of the body, as it certainly would do if it were due to the introduction of a specific poison, which would develop in the blood in the same manner, as we know the specific poisons of small-pox, scarlet fever, and measles do. I assert next that erysipelas may be checked at any stage; that appropriate treatment will stop it at a very early stage in a manner which would be utterly impossible if you were dealing with a specific fever. Let me add, that this will apply to the next stages of those forms of inflammation of the uterus, which is due to erysipelatous contagion, that they are not to be ranked as specific fevers, but as things which may be put an end to by appropriate treatment at an early stage. Dr. Braxton Hicks has just insisted, no doubt as the result of practical experience, on the importance of washing out the uterus; so that the thing is curable, and does not run through any definite stages. Having made this assertion respecting erysipelas, that it is to be defined as a local inflammation, which has special peculiarities that are capable of pretty easy definition, but having no true analogy to specific fevers, I must attempt to give some meaning to the term septicæmia. Now, for that we have two meanings afloat in the professional mind. One is that it is due to some poison which is introduced into the patient's blood from without; that the poison then grows, spreads, germinates in the blood, and produces the symptoms. Now, what I would like to suggest is this, that the term septicæmia ought to be applied to the results of poisoning of blood induced by the inflammation of the patient's own tissues. I admit that every now and then in connection with a "poisoned" wound the phenomena of septicæmia follow. To illustrate what I mean, I will mention two cases. I had to amputate the finger of a professional friend on account of gangrene, the result of acute inflammation, owing to a "poisoned wound". He had scratched his finger on a piece of carious bone, in an operation on the hip-joint. Acute inflammation followed, which passed into gangrene, and I had to remove the finger at the metacarpal joint. He was very ill at the time. This might be called septicæmia, the finger having been poisoned and inflamed. My own belief is that the character of the poison which was introduced was of little or no importance; that there was something special in the state of the patient's health, perhaps something a little irritating in the secretion. The gangrene was the result of in-

flammation, and the constitutional symptoms were the result of the blood circulating through the finger, and back again from a portion of tissue which had passed into gangrene. I once amputated a foot on account of gangrene in a case in which I knew that the man's femoral artery was obliterated. The gangrene was continually spreading, and we were obliged to remove the part. Fearing gangrene, and knowing that there was no femoral artery, I amputated just below the knee. The leg was in a perfect state of health in that part; but within twenty-four hours of the amputation, in connection, no doubt, with a deficient supply of blood, the stump passed into gangrene, which spread rapidly to the thigh; it all became dusky, and the patient was sick; the pulse rose to 160; he was feverish, had a dry tongue, and in fact, was in a condition evidencing acute septicæmia. He was being poisoned, according to the way in which I would like to use this term, by the absorption of fluids from his gangrenous limb. The blood was going through it, and back again, and thus every time the body became contaminated by the circulation; and the man would have died if we had not adopted other measures. Believing that the gangrene was the source of poisoning, I amputated again, at once, below the hip-joint, high up, at a part where the circulation was better. He was extremely ill at the time, but, contrary to my expectation, he made a good recovery. I quote the case as proving that the removal of the source of the poison was efficient in removing the septicæmic symptoms. I may also mention the case of a gentleman who had insured his life in the Accidental Insurance Office. He had slipped in the street, and dislocated his thumb (a compound dislocation), and he died some six or eight days afterwards, with symptoms of septicæmia, vomiting, a rapid pulse, dry tongue, shivering. His hand was passing into a state of gangrene. There was a long legal dispute as to whether he died of the accident, or of something in connection with his general health. I mention this case in connection with the others, as an illustration of what I believe, that it was gangrene of the hand that poisoned the patient. I mentioned just now the case of a medical man who poisoned his finger, in whom gangrene followed, and some of the symptoms of septicæmic poisoning. I wanted to confute the prevalent idea that some morbid matter is taken into the blood from without in every case in which septicæmic symptoms are present, and that that matter is the cause of the symptoms. The next case in which I had to remove a finger, was one almost exactly analogous. It was the case of a poor seamstress who had no poisoned wound whatever. A prick of a needle on the finger had led to gangrene, and she had a similar train of symptoms. We very often get symptoms of septicæmia in cases in which there has been no possibility of their being produced by morbid poison; and it yet is quite impossible to distinguish between the cases in which gangrene follows an injury in a more or less unhealthy person without any introduction of morbid poison, and the cases in which inflammation follows when there has been some possible introduction of a small amount of such poison. I admit the influence of morbid matter as an irritant in setting up inflammation; but what I wish to hint is, that I believe the stage of gangrenous inflammation of the part is an essential stage of septicæmia, and that it is quite possible for pyæmia to occur without any local poison introduced from without whatever. So much, then, for septicæmia. I think we should do well to keep it apart from the term pyæmia, and to believe that in septicæmia there is no phlebitis. In reference to the far more important subject of pyæmia, I think we should give a little more attention to the opinions of our forefathers; and I believe that no one could get more information on this subject from any papers by modern writers than from the original paper which drew attention to the subject, by Mr. Arnott, written some forty-five years ago. Next in importance to the paper of Mr. Arnott, I rank the papers of Dr. Robert Lee: a series of admirable essays on puerperal fever, a perfect mine of correct information upon that subject. If we studied those papers better (in the *Medico-Chirurgical Transactions*) I feel certain that we should not have afloat the very erroneous opinions respecting pyæmia, which have gained admission into some of our most important text-books, very much to the regret of many. The great heresy that at present prevails respecting pyæmia (at least, according to my belief), is, that it is possible for pyæmia to be caused by the introduction of a specific poison from without into the blood. I no more believe this, than I believe that septicæmia is so caused. Pyæmia, I hold, is produced by an inflammation of the patient's own tissues. What we call pyæmia, in more typical cases, is due to phlebitis. The old-fashioned notion is quite true, that it is a poisoning of blood by inflammation of the veins. I regretted that Mr. Spencer Wells was a little vague upon that point. He spoke of coagulation of the blood, and the breaking-up of the coagula. Now, in spite of experimenters upon the lower animals telling us of the difficulty of making the veins inflame, I hold that any

one who goes into the *post mortem* room and examines the veins in cases of pyæmia, will have no doubt that the veins do inflame. Nor am I in the least confuted by the assertion that we have cases of so-called phlebitis without pyæmia; that in cases of coagulation of blood in veins (varicose veins for instance) we do not fear pyæmia, that yet in such cases we do not fear pyæmia. Of course, we do not. The things are totally different; but that there is a suppurative and gangrenous phlebitis in which the veins become full of pus, in which purulent lymph adheres to the ulcerated lining membranes of the veins, I hold to be thoroughly established by the records of surgery, and by daily experience. It is not the breaking down of the blood clot; it is the ulcerative and suppurative inflammation of the vein itself. I could produce illustrations to-night, showing this in various parts in the most typical cases of pyæmia. I do not say that the term pyæmia is to be restricted to these cases. I think it is quite possible that there are other cases in which multiple abscesses are formed, in which there is no phlebitis; but, I believe, we shall proceed on a safe basis of classification if we at any rate accept these most definite forms of pyæmia, which are due to inflammation of the veins as by far the most important group in connection with the disease under discussion.

Dr. RICHARDSON: The view I would start with in regard to puerperal fever rests with the condition of the woman after delivery. She is at that time physiologically in a peculiar position. First, her blood is in a peculiar condition. That colloidal fluid which, separated in a solid form, we call fibrin, is sometimes in excess, from three to six or seven, and (as I once found on a direct analysis) eight parts in a thousand; so that the blood is at this moment in a trembling equilibrium, ready on the slightest possible disturbance to precipitate it. Then there is a diminution of salts in the blood, again a condition favourable to the precipitation of the colloidal fibrin. Then this woman has been for a time supplying to the child a mass of blood from her own body which has now stopped, so that practically she is in the condition of a person who has lost a limb, a considerable portion of the body. Then she is in a nervous condition, she has been supplying from her own potential energy that element which has been shown in the movements of the fœtus, and now that has stopped, and she is suffering from that nervous reaction which comes on when that motion is suddenly arrested; she is, therefore, in the exact condition for a series of changes, which must necessarily be febrile in character; and I think we must bear in mind this position of women physiologically, before we enter upon the subject at all. To these facts we must add those which we have reason to learn in regard to hereditary qualities. We must accept the fact that there are a considerable number of women who are hereditarily predisposed to particular diseases, and, I think, we cannot except puerperal fever from this position. Then we come to consider the woman in this state, and we ask the series of questions which Mr. Spencer Wells has placed before us. Taking these questions one by one, I should say that, from experiment as well as observation, I should be unable to declare that there was any such thing as a special poison belonging to the puerperal state, or a special poison creating puerperal fever. It is quite true that, puerperal fever once started, there is a poison formed which will apparently communicate the disease; but there are certain varied forms of this poison, though, perhaps, all these poisons have one common meaning if we could look at them fully; but there are so many poisons derived from other sources, which seem to have the power of producing the disease, that we cannot look upon this special poison as we do on the poison of small-pox or scarlet fever; neither can we say, in respect of this first question, that there are such local lesions as would lead us in the dissecting room in any case to say, this was a case of puerperal fever, as we should say, this was a case of scarlet fever, or of typhoid, or of typhus fever. In fact, I recollect making a *post mortem* examination some years ago, in a case of what was called puerperal fever, on a lady of some distinction in the metropolis. There were four eminent members of the profession present, and they were none of them agreed on this very point; one said it was a simple case of peritonitis. We then began to discuss whether, supposing this case was going before a jury, and we had to give our opinions, we could formulate in any way a series of pathological changes, which would indicate the cause of death as due to puerperal fever. Or to put it in another way, supposing one of our Fellows had said, "This is a case of puerperal fever; will you make a *post mortem* examination?" would any of us know precisely what we were going to find as distinguishing that diagnosis? I should give a negative answer, therefore, to the question of Mr. Wells, both as regards the special poison and as regards the special characteristic pathology of the disease. In regard to the second question, as to whether any or all of the forms of puerperal fever may be referred to an attack of infective continued fever, as scarlet fever, and so on, I should also offer that a negative. Under the term puerperal fever, as I have been obliged to

recognise it, from being frequently summoned to see cases which are so called, I should say that I have seen four distinct forms of fever which clearly may bear this name. For instance, there is the pure, simple surgical fever, as we may call it, following upon the delivery of the child. I presume there is no such thing (at any rate the exceptions are very rare) as a case of delivery which is not followed by some slight febrile state; that is necessitated by the changed physiological conditions, by the increased tension of the vessels which must occur from the removal of so much blood in the uterine circulation, and by the irritation that has occurred in the breast previous to the secretion of milk. There is always this simple surgical fever similar to that which occurs after a surgeon has removed a limb; this, in fact, is a fever of resistance, as I have called it in a paper that I have written on the subject. Now I am bound to say that I have seen some cases of so-called puerperal fever which were nothing more than exaggerated forms of this fever, which it may be has become exceedingly severe, in which we have had true inflammatory fever, and apparent indications of danger from that source; nay, in one case I have seen a fatal result from the formation of a plug of fibrine in the heart. In that case there was a simple rise of temperature of 4 degs. following the confinement, then a sudden collapse. An exceedingly rich blood, rich in fibrin, had been so modified by that simple rise in temperature, and by the increased friction of the blood passing through the heart, that a deposition of fibrin had taken place in the auricula of the right auricle, that had increased, layers of fibrin had been laid down, layer upon layer, as in aneurism, and ultimately a complete bag of fibrin was formed; there was an extension of that into the pulmonary artery, a loosening of the whole, and then death; yet no trace of the disease in any part of the patient, not in the uterus, not in any organ of the body, except that there was an incidental plugging up of the right side of the heart. We see such cases occurring in simple instances of pneumonia and some other forms of trifling inflammatory diseases. An attack of erysipelas, with a slight blush in the leg, I have known to terminate in a few hours in death in the same way. Then I have seen another form of puerperal fever (many will recall similar cases) of what may be called a remittent character, with slight symptoms or extreme symptoms of jaundice; twice I have seen this coming on with high fever in the puerperal state. In a case in the neighbourhood of London this occurred. It was a pure case of bilious remittent fever, occurring in a neighbourhood where there was no puerperal fever about, and ending fatally in a few hours, with all the conditions of yellow fever. I have seen cases ending fatally with this remittent bilious character pertaining to them in other instances. Then there is another class of cases, such as Mr. Hutchinson referred to, where there is a true introduction into the body of the patient of matter derived probably from the uterine sinuses, and where we get one of the true distinctive forms of septicæmic poisoning—a form in which the material becomes dark, and death takes place from deficient oxidation, and a form where there is a separation of fibrin coming on rapidly, and terminating by stopping the circulation of the blood through the right side of the heart. These cases seem to me to be of that class, mentioned by many speakers here, where there has been some local injury, the exposure of cellular tissue, the rupture or exposure of a vein, the formation of a modified secretion, the absorption of that, and death from what Mr. Hutchinson correctly called poisoning immediately from the patient herself. Then, lastly, there is another source of puerperal cases, where, without doubt, a poison appears to be carried into the body from without; and here comes the singular part of this poisoning, that the poison may seem to belong to any one of the poisonous diseases, so long as it reaches the patient, and that it may not be in the strict sense of the word, so far as we know, a poisonous secretion at all—it is poisonous in the individual sense, but not poisonous as coming from any person who has been poisoned. We have instances of scarlet fever, apparently provoking the puerperal condition in this way; we have instances of erysipelas, and I can adduce examples of all kinds. We have examples of poison derived from other puerperal cases, and we have that extraordinary instance, recorded with great faithfulness and honesty by Mr. Huntley of Jarrow-on-Tyne, where he shows, by a series of conclusive arguments, that a secretion from his own hand was the cause, three times successively, after intervals of several months' practice, of conveying poisonous matter to patients, and so inducing puerperal fever. These are true cases of septicæmic puerperal fever, where we must assume that the poisonous matter is carried from the hand, or by some other channel, into the uterine surface, where it meets with a favourable reception for absorption, and so is conveyed into the body, producing all these phenomena which we have experimentally induced by inoculation. With regard to this second question, I should say that there is no special form of puerperal fever, no one particular type of the disease, which we can say bears that name, but that there are several varied forms of the

disease terminating much in the same way, but having distinct characteristics; that some are contagious, some not contagious; that some spring from what you may call a natural condition of the patient, others from an injury of the patient, others from the introduction of morbid material. This again bears on the third question, "If all cases of contagious and infectious disease which occur under other conditions than that of child-birth are set aside, does there remain any such disease as puerperal fever?" To that I should answer that, barring that natural febrile state which follows upon confinement, as surgical fever follows upon injury, there is no such thing as puerperal fever, and in that I should agree with Dr. Braxton Hicks. As regards the fourth question put forward by Mr. Spencer Wells, the means of preventing the spread of the disease, I have nothing to add to what was said by Dr. Braxton Hicks as to the effect of washing, and the general measure of removing the source of poison and isolating the patient. Then I am brought to the fifth question, relating to the presence of bacteria and allied organic forms in the puerperal state; that, of course, only relates to the pure septicæmic condition, the last of puerperal fevers to which I have drawn attention. On this matter, as is well-known to most of you, I have held for many years—more than twenty-five years—to the purely physical side of the question, and my opinion is in no way changed by the various views which have been more recently announced as to the effect of organic germs and bacteria in the production of these diseases. I am at this moment still more firmly adherent to the physical view, from my recent researches, which have shown me the probable mode of action of these septicæmic poisons, that they all act after the manner of those inorganic bodies, such as black oxide of platinum, manganese, and other bodies of that class, and, in infinitely minute quantities, have the power of eliminating oxygen from the blood, and preventing combination of oxygen with the blood. I take it, that the whole of these poisons act in that simple physical manner, and that, as regards the presence of organic germs and bacteria, they are matters of coincidence; that, where the conditions are favourable for those organic forms to grow and multiply, there they grow and multiply, but that this is entirely coincident; that is to say, the further development of the organic form which can be perceived has no more to do with the production of the disease, than the presence of the maggot in the decomposing meat has to do with the decomposition of that meat. To put the point in a simple way, I remember a point in my child-life which will place the position well before the Society. There is a time in country districts, which is well-known, when sheep fall in the field; they may not be dead, but they are found to be infested by carrion crows, which sometimes injure them severely, picking out their eyes, and doing them a deal of mischief. In my school-days, I remember that we had a debate, whether the fall of the sheep was due or not to the presence of these carrion crows. They certainly did a deal of mischief, and my school-fellows would go out with stones and sticks to drive them away; others thought that it was the heaviness of the fleece that caused the sheep to fall, and we used to put the sheep straight on their legs, to run about again. Now it seems just the same physical cause at work producing the falling down of a woman with this disease from the influence of septicæmic poisoning, and these products which are found are coincidences, beautiful pieces of natural history, influences which, perhaps, are not directly favourable to the progress of cure when once they are developed, but they are purely matters of natural history, removed altogether from the true action of septicæmic poison. I have but a few other remarks to make. My impression is, that in the course of time, we shall arrive at the discovery of certain agents which will immediately stop the action of septicæmic poisons, by their direct physical effect upon the blood, and their influences in holding oxygen in combination with the blood. I have recently referred, in another society, to the effect of quinine in this respect; but that is a bungling crude method of dealing with an agent that will act in such proportions as the ten-thousandth or the hundred-thousandth part of a grain, so as to produce disturbance within the organism. So, dealing with this matter of antiseptics, I should say that, if antiseptics, as they are called, that is bodies which prevent putrefaction, are advanced as a means of curing these particular diseases arising from septicæmic poisons, their action is not because they are antiseptics (because other agents which are not antiseptics possess a similar property) but for the simple reason that they act on a given principle, and many of them act altogether in accord physically, and I might almost add chemically, in neutralising the specific action of these poisonous agents; I mean, antiseptics do not act by destroying germs or organic forms, but they act definitely, by interfering with the poisonous action of the septicæmic material which produces the fatal disease. I predict that in ten years hence, in this Society, we shall see a means of preventing these diseases from septicæmic poisonings as clearly as we now see the means of pro-

ducing them, by the introduction of these poisons in the form of inoculated matter in small-pox by vaccination.

The discussion was adjourned.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 13TH, 1875.

SIR JAMES PAGET, Bart., D.C.L., LL.D., F.R.S., President,
in the Chair.

ON THE PREVALENCE AND SEVERITY OF SYPHILIS AMONG THE TROOPS QUARTERED IN LONDON, AS COMPARED WITH THE RARITY OF THE DISEASE AMONG THE SOLDIERS IN THE GARRISONS OF PARIS AND BRUSSELS; FROM OBSERVATIONS, THE RESULT OF A PERSONAL INVESTIGATION MADE DURING THE AUTUMN OF 1874. BY WILLIAM ACTON, M.R.C.S.

THE author commenced by stating that, on returning to England after the completion of his medical studies in Paris, he was forcibly struck with the severity and the numbers of cases of syphilis in an *unprotected** city like London, as contrasted with a *protected*† city like Paris. In the year 1846, and again in 1860, he brought the subject before the Society, and called the attention of the profession to the fact, that whereas the French and Belgian troops seldom suffered from venereal affections, the British soldier was affected with this contagious disease in the proportion of 181 per 1,000, or one in every five men. During the autumn of 1874, he determined to again visit the continent, and judge for himself what was the present condition of syphilis among the French and Belgian population; so that on his return he might be able to again make a comparison between the three cities, and judge what influence continental police regulations had had in checking, preventing, or stamping out this contagious disease. Before proceeding to the more immediate purport of the paper, the author begged the indulgence of the Fellows, while he ventured to remind them of some of the great general laws which regulate syphilis, and with which hospital surgeons no doubt were familiar. 1. *Syphilis is a very wide spread affection* in England, both among male and female adults; rendering inefficient large numbers of our troops, as shown in the last army returns, where it is stated that, in the year 1873 (the last report published), primary syphilis in the unprotected districts was still so prevalent as to be 123 per 1,000 *per annum*. 2. *As regards the severity of the Disease*: the author thought the complaint less severe than formerly. The authorities in the city hospitals in this respect agree with him, and attribute this to the efficacy of the Contagious Diseases Acts at present in operation at Greenwich and Woolwich, a source formerly of much long-shore frightful disfiguration. The in-patients of the non-government side of the Lock Hospital, as he showed later in his paper, demonstrate that syphilis in women is still a very serious complaint. 3. *That primary syphilis is a highly contagious affection* no one can doubt. The laws which it follows are now clearly known; and experience has shown that for its extension, dissemination, or outbreak, absolute contact is necessary. This being avoided, the disease is under our control, as the primary manifestations cannot be communicated through the air, or by the usual vehicles of infection. Another grand feature of the complaint is that it never (at least in the

* The term "unprotected district" is meant to include the principal cities of the United Kingdom, where women can practise prostitution in any public thoroughfare, at any hour of the day or night, without hindrance, and inveigle men to their homes; and this, too, under the very eyes of the authorities, who are powerless to interfere, unless the solicitation be to the annoyance of any passenger or householder, who must in that case accompany the police to the station to charge the woman with the offence, which is rarely or never done. Should the authorities have credible evidence that the woman so conducting herself is suffering from a contagious disease which she may communicate to others having relations with her, they cannot in any way interfere to prevent it. This woman, when unable any longer (in consequence of the severity of her disease) to follow her miserable calling, has no other resource (prostitution failing) to procure her a livelihood than to fall back on the foul wards of a workhouse.

† A "protected district" is one where, if a woman, instead of continuing wholly or in part to gain an honest livelihood, walks the streets soliciting different men, and consequently comes under the cognisance of the police as being a common prostitute, the British Legislature has determined that in certain garrison-towns such a woman, after being repeatedly warned, and still persisting in a life of prostitution, shall submit to a medical examination on the ground that, should she be diseased, she would communicate a contagious complaint to those having relations with her. It is further enacted that, if the woman be found diseased, she shall be at once sent to hospital, and not allowed to leave till she is, in the opinion of the surgeon, perfectly cured. If then desirous of abandoning her evil courses, the girl is relieved from further surveillance, and will be sent to her friends at the government's expense. If, on the other hand, a common woman, on being discharged from hospital, and released altogether from the operation of the Acts, return to a protected district, and be again found by the police acting as a public prostitute, she must again be registered. In every case the authorities wish it to be clearly understood, that they do not sanction or authorise prostitution; they only watch over it, from their anxiety to prevent its worst evils, and to ameliorate the condition of the women and check disease.

present day) arises *de novo*: unlike some other epidemics, this affection, syphilis, is traceable to communication from some person previously affected. 4. *Syphilis can be prevented and stamped out.* Mr. Acton stated that, if he carried his hearers with him in the acceptance of the previous propositions, they must agree with him that the best way of prevention consists in offering men who have exposed themselves to infection a ready means of ablation; and the army authorities have now done this. The next broad principle is, as speedily as possible to destroy the local focus of contagion, so as to prevent extension of the disease, and to warn the male patient against infecting others. The institution of hospitals, free or otherwise, where the already infected may at once apply, is another valid and important means of prevention. Experience in all countries has determined that the mere treatment of these women as out-patients is a vain delusion. What we require is, that by segregating prostitutes as soon as diseased, we should at once prevent them contaminating others. To do this effectually, legislative measures have been necessary, and the women must not be allowed to leave the hospital till entirely cured. The author showed that wherever this has been done, it has succeeded without exception, in all countries and with all classes. Those who are sceptical on this assertion, are referred by the author to the instances of Hong Kong and Dartmouth, where the disease has been reduced to a minimum. Having made these preliminary observations, the author proceeded to describe his continental experience. The first city he visited was Brussels. In his search after syphilis, he attended the wards of the Military Hospital. There were only three cases of syphilis among the private soldiers, and among the non-commissioned officers he saw only two instances of men recovering from primary syphilis, and these were out of a body of troops amounting to 3,500 men. There were only nine women confined in hospital in consequence of venereal disease; showing that in Brussels the police regulations have nearly stamped out the disease. Proceeding to Paris, Mr. Acton, in visiting the French Military Hospitals, could only discover six cases of primary disease, and eight cases of secondary syphilis, 14 cases in all, among the 3841 men forming the garrison of Paris. The author then described the disease among the females, and showed that syphilitic affections are very slight among the women who avowedly give themselves up to prostitution; and attributed the decrease to the police regulations. Mr. Acton gave a table showing that, in the St. Lazare Hospital, he could only find 23 cases of primary disease out of 202 patients confined in this institution, which is specially given up to women, under the surveillance of the police. This small number, however, would have been sufficient to have inoculated the garrison of Paris, had they been allowed to remain at large. Mr. Acton called attention to the fact that medical men in Paris assert that the British traveller, like the English sailor in French harbours, is the source of much of the syphilis to be met with in France; and that the disease would ere now have been stamped out had it not been that England and other unprotected countries are constantly flooding France with fresh cases of primary contagious disease, interfering much with its sanitary cordon. Returning to London, Mr. Acton personally attended the Hospital of the Foot Guards. Here he found disease in proportions for which he was unprepared; there were 24 cases of primary disease among 408 single men in the 2nd Battalion of Coldstream Guards quartered in London. In the 1st Battalion of the Scots Fusilier Guards, Mr. Acton was shown 25 cases of severe forms of syphilis among 505 unmarried men. To obviate the objection that these comparisons were founded on insufficient data, Mr. Acton gave a table extending over twelve months, in which were shown the syphilitic affections of upwards of 3,000 men in the Foot Guards quartered in London. One-fifth of the whole, or one man in five, was affected with primary syphilis during the last year (1874); and he contended that, as there were five battalions of Foot Guards quartered in London, it might therefore be stated that one out of these battalions suffered from primary syphilis. Now, judging from the experience of private practice, this battalion of sick, composed of 600 men, must have been incapacitated from duty for at least six weeks or two months. It was almost equally certain that 164 of these men had relapses of secondary symptoms further incapacitating them for duty for another two months at least; during which time they must necessarily have taken mercury, leaving the constitutions of the men very much debilitated, and liable to relapses during the subsequent years. Mr. Acton then went on to compare the syphilitic affections of the Foot Guards with those found in French soldiers quartered in Paris, and showed that a single battalion of 500 men in London presents more disease than the 3,841 troops composing the French garrison. The author next called attention to the severity and frequency of the disease among the women in London, as compared with those in Paris, and considered that one-half of the London prostitutes were diseased; whereas of those in the protected districts, and under the Contagious Diseases Acts, only about eight per

cent. were found affected at the periodical examinations. Mr. Acton next compared the garrison of Woolwich, which is under the Acts, and where the women are taken care of, and showed the comparative paucity of disease there. It appears that during the years 1871-2-3, 1,085 cases of primary syphilis only were treated in hospital, out of a garrison of 18,250 men. This showed that only one man is affected out of seventeen soldiers in a protected district like Woolwich, instead of one man in six, as in London; and, from a table given, it appeared probable that had the protection offered at Woolwich been afforded by the outlying districts, only one man in thirty-four would have been subject to contract syphilis, as at least one-half of the cases of syphilis were contracted out of the district, bringing it to something like the small proportions witnessed in Paris. In concluding, the author remarked that, when he read his last paper on this subject before the Society, he could only recommend the supervision of prostitutes as an experiment, backed as it then was only by the experience of the Continent. Now he could speak of this as an accomplished fact, and one that, as he had shown, had succeeded in a sanitary point of view beyond the expectations of its supporters.

Dr. DRYSDALE thanked Mr. Acton for the manner in which he had brought the subject forward. When he (Mr. Acton) first stated his views in 1860, they met with much opposition; but he had steadily adhered to them, and had now put the matter in a shape capable of discussion. Dr. Drysdale would confine his remarks to the experience of the regulations of prostitution in foreign countries. The question of preserving soldiers from syphilis was a very different one from that of keeping off the disease from the general population. The pay of soldiers was low, and they were hence obliged to be contented with the lower class of women, who were naturally massed together, and, therefore, were capable of being looked after; and Mr. Acton had proved his point with regard to the immunity of the troops in Belgium and Paris, both in 1860 and in 1874. But when men had higher wages than soldiers, and were able to make their choice, it became impossible to examine in the same way the women with whom they consorted. He formerly believed with Mr. Acton, that there was much less venereal disease in protected countries than in London. While studying in Paris, he had seen a great deal of old tertiary syphilis under M. Nela-ton. In 1867, he again visited Paris, for the purpose of inquiring into the frequency of syphilis, hoping at the time to find that Mr. Acton's ideas were correct. On the contrary, there was apparently more syphilis in Paris than in London; and M. Le Fort, who had knowledge of the state of venereal disease in both cities, agreed in this. M. Jeannel of Bordeaux, in a recent work, stated his belief that there was more syphilis in Paris than in London. M. Diday, in 1874, also acknowledged the failure of police regulations; and other authorities in Paris made similar statements. Mr. Acton had said that he found the troops in Brussels free from syphilis, but the disease was not stamped out in that city. In a lecture delivered last year, M. Thiry alluded to the numerous and severe cases in his wards. He (Dr. Drysdale) thought, therefore, Mr. Acton rather sanguine as to the stamping out of syphilis. The French system was confessed by French authors to be a failure; and it was curious that attempts should be made to introduce it in England and in the United States.

Dr. BIRBECK NEVINS had entered on the inquiry with the expectation of finding that good results had been produced by the Contagious Diseases Acts; but, on perusing the report of the Royal Commission, he found no evidence of a diminution of the disease in 1870 as compared with 1866. Before the Acts came into operation, gonorrhoea in the army had diminished by one-twelfth; but now the amount of this disease was higher than before the Acts were in operation, and the last return stated it was higher in the protected than in the unprotected districts. Dr. Balfour had admitted that the Contagious Diseases Acts were a failure as regarded gonorrhoea. In the Navy, also, gonorrhoea was much more prevalent in the protected stations; in the home and Mediterranean stations it had more than doubled since 1866. As to venereal disease, he would first speak of constitutional syphilis. Before the Acts, from 1861 to 1866, there was a fall of one-fourth of the whole amount in the Army; but since the Acts, there was an increase of one-twelfth above the previous amount. There had been a fall in the amount of primary cases since the Acts had been in operation; but a comparison of the numbers from various towns would give the following results. In Devonport and Plymouth, the average annual fall per 1,000 was, before the Acts, 10.8, after, 7; in Portsmouth, before, 15, after, 10; Chatham and Sheerness, both before and since, 4; in Woolwich, before, 18, since, 3½; at Aldershot, before, 7, since, 3.6; at the Curragh, before, 10, since, 11; at Shorncliffe, before, 9, since, 6; at Dover, before, 8, since, 11; at Maidstone, before, 60, since, 21; while in London the fall had been reduced from 96 to 40. In Winchester and Canterbury the fluctuations were so great that no conclusions

could be drawn. Colchester alone showed a remarkable improvement, the average fall per 1,000 having increased from 28 to 55. In the Navy, there was no station with so little improvement in this respect as the home station. In the Mediterranean, since the Acts came into operation, the number of primary venereal sores had doubled. In the unprotected stations, the sores were cured more rapidly. Among the constantly sick from syphilis, there was a fall of one-third previously to the Acts; but since the Acts the fall per 1,000 had been from 6½ to 5½. The number of men invalided for secondary syphilis had risen since 1866 one-twelfth in the Army, and one-fifth in the Navy. Venereal disease had increased 17 per cent. in the regulated districts since 1866, and the deaths were just doubled.

Inspector-General LAWSON would make some remarks on Dr. Nevins's statistics. It was a feature in his address that he had compared single years—1866 and 1872; and he had not shown that any reduction would have taken place, if the Acts had not been in force. It would be seen, on examining the curve of disease from 1860, that there was a diminution in the frequency of venereal sores down to 1866, while after that there was an increase, with fluctuations, in unprotected stations. No conclusion could be come to as to the course of venereal disease, unless it were studied where not interfered with by the Acts. Dr. Nevins had compared a minimum with a maximum year; but no inference could be drawn from such a comparison. Again, as to particular stations, many were not aware that most remarkable variations occurred at the same stations in contiguous barracks. Having occasion to inquire into the frequency of disease in the infantry at Aldershot, he had, in examining the middle block, found that a regiment had had 42½ per 1000 of venereal sores; and that others, one on each side of it, had 84 and 124 per 1000 respectively. He then examined three regiments in the North Camp, in which the numbers per 1000 were 23, 59, and 114 respectively. All this was in the same place and at the same time. There were, therefore, circumstances affecting the spread of venereal disease which were not yet known; and no conclusion could be drawn from examinations of single masses of men. Dr. Nevins said that secondary syphilis had become more frequent lately; but he drew a different conclusion from the returns. There had been a change of nomenclature, which Dr. Nevins had perhaps overlooked. Before 1860, secondary syphilis was returned under three heads: secondary syphilis, syphilitic iritis, and syphilitic cachexia. It was necessary to take several years together, in order to arrive at a conclusion. In five years before the Acts, in 374,000 men (being an annual average of 74,800), the rate of secondary disease was 34 per 1000; while in five years (1866 to 1872), since the passing of the Acts, the annual rate in 380,000 men (76,000 *per annum*) was 25 per 1000. Secondary syphilis varied from year to year; and, in years when the number of cases of primary syphilis was small, that of secondary syphilis was also small. With regard to discharges from the army on account of syphilitic disease, there was a difficulty to some extent, arising from the fact that, up to 1863, the discharges on account of syphilis were not recorded separately from those on account of other diseases. But, taking the two periods of five years 1863-67 and 1868-72, the discharges *per annum* were in the first of these periods 13.4, and in the second 13 per 1,000; the latter period including two years in which a great reduction was made in the army. In considering the question of the number of men under treatment, Dr. Nevins had again compared 1866 with a subsequent year, without noticing the intermediate period. The average daily number of cases of primary syphilis in hospital in 1866 was 6.35; in 1860, in places not under the Acts, it was 9. Of secondary syphilis, in places under the Acts, the average daily number under treatment in 1867 was 6.95 per 1000; in 1873, it was 4.33. From the beginning of April 1868, medical officers in charge of troops had had to make returns of the cases of venereal disease not originating in the localities in which they were located. These numbers had now accumulated, and, at Aldershot, the average of primary sores from 1868 to 1871 was 66.8 per 1000, but of these 19 cases per 1000 were from places beyond the district, leaving an average of 47.8; which, taking into account the men on furlough, and making allowance for the men who contracted disease at Aldershot, but left before coming under treatment, would probably be raised to, at most, about 50. The same was probably the case at all the stations under the Acts. Before the Acts, the average of gonorrhoea at Aldershot had been 95 per 1000; but it had now fallen to about 75.

Mr. HOLMES, as probably the only member of the Commission on the Contagious Diseases Acts who was present at the meeting, would make some remarks. It had been said by Dr. Nevins that the Commission had reported that there was no evidence that periodical examinations had diminished the amount of disease. He admitted this; the statement was made, because at the time there was not sufficient material on which evidence could be founded. The portion of the report referred

to, however, was not approved by a minority of the Committee, including all the medical members except Dr. Bridges and Mr. Holmes Coote, who were in favour of voluntary action. Hence, this part of the report was of no value, being founded not on evidence, but on want of evidence. As to the general question, it would be seen that Dr. Nevins's figures afforded no foundation for annual averages; they only showed fluctuations, but no law could be deduced from them. What had weight with the Commission was not so much mere figures, as the evidence of medical men of the army and navy and of others, as to the good effect of the Acts. There was evidence given that the Act had reduced the frequency of venereal disease and mitigated its type. This had more weight than figures, notwithstanding that the figures were as strong as could be expected considering the short period during which the Acts had been in operation and the interfering causes. In referring to the Commission, it should not be forgotten that the Act was continued by its advice, and that it recommended Parliament to show the same vigour in the matter as had formerly been shown with regard to vaccination.

Mr. R. B. CARTER said that Dr. Balfour had been spoken of as if he were opposed to the Acts. When the *Victor Emmanuel* hospital-ship visited Southampton, he (Mr. Carter) had had occasion to visit the ship, and had had a conversation with Dr. Balfour, who had expressed his opinion of the high utility of the Acts, from his observation of the good which they had done. If Dr. Nevins's observations proved anything, they were an endeavour to show that there had been an increase of venereal disease since the Acts had come into operation. But was it consistent with common sense to admit this? The question to be decided was, whether they diminished disease sufficiently to make it worth while to keep them in force.

Dr. DE CHAUMONT referred to the diagram published by Dr. Nevins in the *BRITISH MEDICAL JOURNAL* for March 27th, and remarked that it would be seen that after 1866, when the Acts came into operation, there was a fall both in syphilis and in gonorrhoea as compared with the period before the Acts. He also showed diagrams, in which were given curves representing the strength of the Royal Engineers and the cases of disease, showing that in the unprotected period the cases of disease bore a much greater proportion to the strength than afterwards. Here, in the unprotected period, the curve of admission was above the line of strength; in the protected period, it was below, and fell in a diminishing ratio. As to the intensity of the disease, a German surgeon had expressed his surprise at the number and severity of the cases at Netley, remarking that there was nothing like it in Berlin.

Mr. T. BOND made some remarks on the statistics of the Westminster Lock Hospital.

Surgeon-Major HUTTON remembered seeing a large number of cases of venereal disease at Plymouth in 1860. Since the Act had been in operation, he had found only three or four cases on inquiring at Dover.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 9TH, 1875.

SIR WILLIAM JENNER, Bart., M.D., D.C.L., F.R.S., President, in the Chair.

Disseminated Cerebro-spinal Sclerosis.—Dr. BUZZARD exhibited a patient suffering from this disease. The man, a house-painter, aged 33, but looking many years older, was wheeled in a chair to the upper part of the room, and beside him was placed another man affected with paralysis agitans; and Dr. Buzzard then proceeded to compare the symptoms by which the two diseases, often confounded, could be distinguished. The patient with sclerosis, whilst seated and with his limbs in repose, showed no signs of tremor in any of his muscles; whilst in the other man there were constant rhythmical movements, which could be seen even at a distance, and his hands maintained the position characteristic of paralysis agitans, the thumb being applied to the forefinger, as in taking a pinch of snuff or rolling a cigarette. The head of the latter patient was projected stiffly forwards; the chin of the former rested easily upon the upper part of the chest, for the reason that an effort to hold the head upright caused violent agitation of the muscles at the back of the neck. Asked to rise, the patient with disseminated sclerosis made at first several ineffectual efforts, his whole body being thrown into violent tremors, the feet being lifted from the ground when evidently he wished to stand upon them; and he attained at last the standing position, and took a few steps only with the help of an attendant. The patient with paralysis agitans rose without increase of tremors, and walked easily, but with a hurrying gait, the body bent forward. In answering questions, the articulation of the patient with

sclerosis was observed to be greatly embarrassed, the words being clipped and uttered in jerks, syllables being often repeated three or four times, so that it was very difficult to comprehend him. The patients were then removed, and Dr. Buzzard gave some details of the case of cerebro-spinal sclerosis. The man had ordinarily enjoyed good health; but, about two years ago, he was attacked with shakings of the arms and legs, only when he wished to move them. These increased, and, after six months, he had to give up work, but remained able to walk until six months ago. For the first six or eight months of his illness, he suffered only from the shakings; but then he began to have attacks of giddiness, with difficulty of articulation, and found that he could not read many lines without confusion in the type. At the same time, he began to experience numbness in the lower extremities, which still continued. The giddiness he had not felt for the last three or four months. At present, there was some, but not much, deficiency of power in all four limbs. There was slight dulness of sensibility in his lower extremities, but no impairment of the functions of the bladder or rectum, and no loss of sexual power; nor was there loss of muscular sense. He did not suffer from flying pains, like those of locomotor ataxia, but he was subject to pain at the top of the head occasionally. The sense of smell was intact, the sight somewhat enfeebled. There was no paralysis of the third, fourth, sixth, seventh, and eighth nerves. The action of the masticatory muscles was a little irregular, and there was tremulousness of the tongue. His wife thought him as intelligent as ever; but, as he could not speak except with difficulty, or read without embarrassment, or rise to his feet without help, he passed his time in a chair, doing nothing, and his face wore an aspect of helplessness. If he took a newspaper, he would read perhaps twenty lines fairly, but then he became confused, skipped several lines, or returned to one already read, and was forced to give over. The ophthalmoscope showed dark greyiness of the optic discs, the vessels very tortuous, and not tortuous; the outlines of the discs not sharply defined. In his remarks, Dr. Buzzard mentioned that, although the anatomical characters of this disease had been pictured by Cruveilhier nearly forty years ago, and about the same time by Carswell in this country, and although since that time many cases of the affection had been recorded by Türck, Frerichs, Valentiner, Hasse, Niemeyer, and Leyden, it was certainly to Dr. Charcot of Paris that the credit was due of differentiating the disease from other forms of paralysis, and especially from paralysis agitans. This had been done during the last few years, and the diagnosis had been made so clear, that it was almost impossible to understand the cause of any confusion in the two disorders, whose pathology, he might add, differed completely. Whilst the symptoms in disseminated cerebro-spinal sclerosis were always dependent upon the presence of scattered patches of indurated and condensed connective tissue throughout the brain and spinal cord, there was no constant lesion to be found in those who died with paralysis agitans. Dr. Buzzard added, that he did not bring forward the case as a pathological curiosity, but with the hope that, the more widely known was the knowledge of the peculiar features of the disease, the more likely it would be that valuable information would be gleaned as to its earlier stages. In hospital practice, it was only seen when confirmed, and then it was too late to treat it with any hope of success.

Dr. BUZZARD said, in reply to a question from the President, that as the patient had had to do with lead, and had a blue line on his gums, iodide of potassium was being given to him, not, however, with much hope that it would do good. A trial was also, he added, being made of the Russian needle-bath, which had appeared to be of some service in a case of the kind.

Unusual Case of Lead-Poisoning.—Dr. Downer read the clinical notes of a case of chronic paralysis, upon which suddenly supervened a diffuse general paralysis. The paralysis was not confined solely to the motor centres, but extended to the general encephalic mass. He prefaced the case by remarking, that the action of lead upon the various centres must at all times be replete with interest for many reasons. In some instances, it influenced trophic nerves, and gave rise to subacute inflammation of joints. In others, the abdominal plexuses were solely involved. Again, certain spinal nerve-centres were alone affected; while, lastly and most rarely, the encephalic functions were materially disturbed. The patient, of obscure family history, was 26 years of age, and by trade a painter. He had suffered from painters' colic upon several occasions, but otherwise his health had generally been good. When admitted into the Central London Sick Asylum, he gave one the idea of a man suffering from progressive insane paralysis in its later stage. The intellect was obtunded and confused, and, although he tried to answer questions, he failed. The eyes were dull and hazy; the arms and forearms were partially raised, and the hands dropped listlessly at the wrists. He could not raise the legs from the ground without great effort. There was partial suppression and absolute reten-

tion of urine, which was highly albuminous, of gravity 1020. The clinical details were minutely described up to the man's death, which took place four days after he came under Dr. Downer's care. The temperature at the time of death was 110 deg. Fahr. At the *post mortem* examination, it was stated, in connection with the brain, that the straight sinus was occluded by a well organised and adherent clot, and that there was subarachnoid hæmorrhage over the left parietal and occipital lobes. The microscopic examination of the cord and medulla gave evidence of degeneration of the gray matter, as well as abundant millary sclerosis of the lateral and anterior columns. Upon chemical examination, the substance of the brain and cord was found to contain about $\frac{1}{100}$ th of a grain of lead in each inch.

Dr. Downer stated, in reply to the President, that the flexor muscles were not analysed; they might or might not have contained lead.—Dr. THORNTON inquired if anything special were noticed with regard to the intestine; it had been said, on the one hand, to be dilated, and, on the other hand, to be spasmodically contracted.—Dr. Downer replied, that both the intestines and the solar plexus had been examined, but that nothing particular had been noticed with regard to either.—Dr. BUZZARD remarked that lead was used as a styptic remedy, and yet this man, who was fully under its influence, actually died from hæmorrhage.—Dr. SOUTHEY inquired whether any special microscopic change was found about the vessels of the brain.—Dr. Downer said the man's preliminary symptoms were those of lead-palsy; he died actually from suppression of urine and extravasation of blood on the hemispheres. The large vessels of the brain were not atheromatous. The hæmorrhage was beneath the pia mater rather than subarachnoid. There was no history of addiction to alcoholic liquors. The kidneys were simply congested; their capsules were easily torn from the cortices. There was a purple condition of the kidneys, as is seen in acute inflammation of red degeneration is arrived at. It seemed to be a case of chronic lead poisoning; but Dr. Downer was sorry the condition of the vessels of the brain was not more thoroughly examined.

Intracranial Aneurism, diagnosed during Life, by a Spontaneous Cerebral, and the Paralysis and other signs.—Mr. JONATHAN HUTCHINSON read notes of the case. The patient, Mrs. S., first came under his care in March 1861. She was then 40, thin, and extremely pale. For ten years or more, she had been subject to bel headaches. A year before coming under care, these became much worse, and were attended by severe throbbing in one temple, which sometimes lasted two or three days, and by a "beating under the ears". About the same time, her left eyelid dropped, and vision became dim in that eye. These symptoms persisted, and caused her to seek advice. On admission, there were on the left side complete paralysis of the external rectus, incomplete paralysis of the recti supplied by the third nerve and of the levator palpebre; the papillary sphincter and ciliary muscle were paralysed; the superior oblique was perfect. The dilator of the iris (vaso motor) was probably paralysed on her admission, and certainly was so a fortnight later, when she also had some loss of sensation of the left side of her forehead. There was no reason to suspect syphilis. An intracranial bruit was heard on auscultation of the head. A few months later, all branches of the third nerve became completely paralysed, the fourth still remaining perfect. There was now some implication of all the sensory divisions of the fifth nerve, but none of its branches were completely paralysed. The facial nerve remained perfect. She remained during the succeeding ten years in much the same state, suffering at times from very severe internal headache, and, during the early part of the time, from throbbing. The fundus of the eye was healthy throughout; the other eye and orbital nerves were healthy. Aneurism of the internal carotid was diagnosed confidently by Mr. Hutchinson early in the case, and ligation of the carotid artery proposed, but deferred at the patient's urgent wish, expressed in consequence of a less confident opinion having been given by a colleague. The chief question was between aneurism and pulsating tumour. After this, the throbbing slowly subsided, the paralysis remaining; health improved somewhat, and the question of craniotomy and trepanning. Vision of the eye remained tolerably good. In February 1871, Mr. Hutchinson found a large pulsating tumour in the abdomen, which was confidently diagnosed as aneurismal; it was then of about six months' duration. Its early progress had been accompanied by pain in the abdomen, pain in the left leg, constipation, and inability to take food. For some weeks, she was nourished solely by enemata. Death occurred early in May 1872, she having had a large abscess in the left iliac fossa in connection with disease of bone from pressure of the aneurism. At the necropsy, a solid aneurismal tumour, of the size and shape of a bantam's egg, was found to occupy the inner part of the left middle fossa of the skull. The internal carotid passed along its inner side, and a well-defined smooth-edged aperture, as large as a No. 6 catheter, opened from the outer wall of the vessel into the sac. The distal branches

of the artery were pervious. The optic nerve was in close apposition with the tumour, but it exhibited no evidence of compression. The Casserian ganglion was situated directly beneath the tumour, and flattened by it. The motor nerves of the eyeball were lost on the wall of the aneurism. The aneurism was nearly solid; the opening admitted a probe only an eighth of an inch; its wall was in great part calcified. A large dissecting aneurism of the aorta was found extending from the commencement of the thoracic part to the bifurcation of the abdominal portion.—In reference to the propriety of operation, Mr. Hutchinson added that he thought its proposal had been quite justified by the group of symptoms present—the throbbing in the head, the *bruit*, the paralysis of the several nerves in succession—without other assigned cause. On the whole, although the patient had survived so long, he thought it was a matter of regret that the operation had not been done, as the tumour would probably have been arrested at an earlier stage, and more completely. He urged also that it should be remembered that, during the first part of the case, there was from day to day considerable risk of bursting of the sac. He mentioned another case, which had been under his observation once only, in which a lady from the country, who had some symptoms of aneurism of the internal carotid, was seized with giddiness whilst sitting in church, and died before she could get to the door, the necropsy revealing a ruptured aneurism.

Mr. CARTER inquired whether any observations had been made with regard to the channel through which the blood escaped from the eye. Was there any enlargement of the cavernous sinus, or of the veinlets in connection with the facial vein? Was there any compensatory development elsewhere?—The PRESIDENT asked whether, in the second case which had been mentioned, there was any ptosis.—Mr. HUTCHINSON said there was paralysis of the sixth nerve; but he did not think she had ptosis. A case had been recorded in which there was ptosis, and in which, when apoplexy occurred, there was immediate loss of ptosis. As the *post mortem* examination was done at the patient's own house, there was no opportunity of testing the condition of the orbital and other neighbouring veins by injections. He did not doubt the circulation was principally conducted by the veins passing over the margin of the orbit to join the facial vein. An anatomist as able as Mr. Hilton had expressed his belief that the ophthalmic vein did not chiefly empty itself by the cavernous sinus. This case, at any rate, showed that in this woman the collateral circulation through neighbouring veins was as great as that by the cavernous sinus. The fundus of the eye was healthy throughout.

Three Cases of Pyæmia and one of Acute General Miliary Tuberculosis, complicated with Pyæmia, caused in the three former cases by Acute Suppuration; in the latter, by Chronic Inflammation and Caseous Deposit in the Middle Ear.—Dr. HERMANN WEBER communicated these four cases.—CASE I. A girl, aged 6, was, on the fifth day of scarlet fever, seized with severe pain in the left ear, rupture of the tympani on the sixth, severe rigor, with high fever (almost 107 deg. Fahr.), on the eighth day, followed by other rigors on subsequent days, abscesses on different parts of the body, pericarditis and pleuritis, and death on the fifteenth day from the beginning of the affection of the ear. The *post mortem* examination showed the left tympanum filled with pus, the phenomena of thrombosis in the small veins near the tympanum and in the left jugular vein; those of fresh endocarditis and pericarditis, and pleuritis; abscess in the liver, and embolic infarctus in the spleen.—CASE II.—A boy, aged 7, had, on the eighth day of a diphtheritic sore-throat, violent pains in the left ear, followed, on the tenth, by rupture of the tympanic membrane, and profuse purulent discharge. Rigors set in, with high degrees of pyrexia (up to 107.3 deg. Fahr.), on the eleventh day, and recurred at irregular intervals during three weeks, with almost normal temperatures between the attacks. Abscesses formed in several joints and at different parts of the surface of the body. The treatment consisted in large doses of quinine; viz., from 60 to 110 grains in twenty-four hours, port wine, and nourishing food. The recovery was slow, but perfect.—CASE III.—A young man, aged 21, had much pain in the right ear already on the fifth day of a feverish sore-throat; this was rapidly followed by rupture of the tympanum and profuse purulent discharge; and, two days later, by an attack of rigor, with high fever and profuse perspiration. Several such attacks occurred during the succeeding fortnight, separated by intervals of but slightly raised temperature. Abscesses formed in the mastoid region, and on different parts of the body; and there was also a slight endocardial affection. Gradually, however, the rigors became less severe, the discharges from the ear ceased, and the deafness, which had been complete on the affected side, disappeared. The treatment consisted in large doses of quinine (eighty grains per day), with iodide of potassium (twenty grains per day); in the local application of diluted carbolic acid, and in port wine and nourishing

food.—CASE IV.—A formerly healthy boy, aged 10, began to complain, about twelve days after an ordinary sore-throat, of pain in the right ear, with deafness on that side. The prominent and yellowish appearance of the tympanic membrane, as seen about three weeks later, led to the suggestion of perforation of the membrane, which suggestion, however, was not acted upon. About three months after the occurrence of the original sore-throat, the symptoms of acute miliary tuberculosis of the lungs manifested themselves, and were rapidly followed by those of tubercular meningitis. The *post mortem* examination exhibited the phenomena of general acute tuberculosis of the lungs, the pleura, the pericardium, peritoneum, and of the cerebral and spinal meninges; and, in addition, several pyæmic abscesses in the liver. The right tympanic cavity was filled with so-called caseous matter; the tympanic membrane was thickened and yellowish, the petrous bone and mastoid cells being normal. Dr. Hermann Weber remarked, that the points in common to all four cases was, that inflammatory affections in the region of the tonsils and fauces had led through the Eustachian tube to inflammatory affections of the middle ear, and to subsequent infection of the whole system; but that there was this remarkable difference, that the general infection caused in three cases by the acute inflammation and suppuration was pyæmia, while that caused by the chronic inflammation leading to caseous deposit or metamorphosed pus was acute miliary tuberculosis, with only some traces of pyæmia in the liver. He was inclined to think that, if the general infection in this latter case had occurred at an earlier period of the disease—viz., before the pus had been transformed—the result would have been pyæmia, as in the other three cases, and that possibly the pyæmic abscesses in the liver had been formed at that earlier period alluded to.

Dr. HILTON FAGE remarked that, in regard to Dr. Weber's fourth case, there did appear to him to be a third view, to which he himself would incline; viz., that the caseous deposit in the ear and the general miliary tuberculosis were disconnected. He gave reasons and quoted cases in support of his opinion. In a child, six months old, which died of miliary tuberculosis, the general disease could hardly have been due to any pre-existent change. In another case, in which there was a large caseous mass in the brain, the tuberculosis in the lungs was not spread equally through the lungs, but was found in greatest quantity at the apex, whence it gradually diminished in intensity towards the lower lobes. This opinion of the non-infection of tubercle in the human subject was so heretical at the present day, that, in regard to cancer, he would remark that he held with the modern view of dissemination, and that those are true secondary deposits which are found in the lungs, liver, etc. Yet there is surely such a thing as diffusion without infection; thus psoriasis, with a few chronic patches on the knee, may suddenly break out all over a patient; the same with molluscum fibrosum. Dr. Weber's case was too rare an event for one to suppose that general tuberculosis usually depended upon local mischief.—The PRESIDENT said he had seen about ten days before a patient with sore-throat and a few diphtheritic patches, in whom a discharge from the ear had occurred, followed by pyæmia. He must agree with Dr. Fage in the view that the reasons for crediting the infection of tuberculosis were insufficient. Neither did he think the arguments recently put forward in favour of the secondary infection of cancer carried the day; in his opinion, the two sides were so evenly matched, that one might be doubtful which side had the advantage.—Dr. WEBER confessed that, in many instances of tuberculosis, he had been unable to find the primary deposit; Virchow also said the same thing. But, in so very many cases, an old affection did precede the outbreak of acute miliary tuberculosis, that the latter seemed to be dependent upon it. Pyæmia was often caused by a focus of pus; and yet how many foci of pus there were in which pyæmia did not supervene.

TESTIMONIAL.—On March 26th, a testimonial was presented to Dr. W. M. Mackenzie of Kelso by a number of his friends and patients. The handsome sum of £570 was subscribed; and, on the day mentioned, the Chairman of the Committee, Mr. Tait of Laryrigg, presented Dr. Mackenzie with an elegant mantle timepiece and a cheque for the balance of the amount subscribed. The timepiece bears the following inscription. "Presented to W. Mackenzie, Esq., M.D., Kelso, with five hundred guineas, by his friends and patients, on the completion of his twenty-fifth year as a medical practitioner in Kelso and neighbourhood, in testimony of the high estimation in which his professional and public services during that long period are held, as well as the regard and kindly feeling entertained for him by them. March 26th, 1875."

At the anniversary court of the governors of the Newcastle-on-Tyne Infirmary, the Mayor in the Chair, Dr. Frederick Page, late senior house-surgeon, was presented with a beautifully illuminated address in gilt frame.

CORRESPONDENCE.

CONTAGIOUS DISEASES ACTS.

SIR,—I regret to have to trespass on your space again, to offer some remarks on the reply of Dr. Nevins, of the 5th instant, to Dr. Parkes, Mr. Ffolliott, and myself. Had my contribution to the *Medical Times and Gazette* been published in the BRITISH MEDICAL JOURNAL, this would not have been required, as I should have left your readers to draw their own conclusions after having the evidence on both sides before them; but, as your paper will be in the hands of many who have no opportunity of perusing the other, this communication becomes necessary.

Dr. Nevins has expressed his anxiety, on more occasions than one, to depend on official returns only, to insure accuracy in his data; and everyone desirous of dealing with the question in the true spirit of investigation will agree with him in the importance of having the materials he is to work on as trustworthy as possible; but, in addition to the mere numerical records of cases, expect them to embrace references to the views or explanations of others. In my communication to the *Medical Times and Gazette*, the passages in Dr. Nevins's statement commented on were transcribed at length; yet in his reply of the 5th instant, he says "the bulk of that criticism is occupied upon the following paragraph of my 'statement'." Such, then, is the nature of the error," etc. Now, the paragraph here referred to does not appear in the article in the *Medical Times and Gazette*, and does not convey to anyone, who has not seen that article, an adequate idea of the question raised, or of the weight of the evidence in support of it. As, however, we are informed that "the battle is now being fought upon other grounds than the fallaciousness or otherwise of a particular process, it is not necessary to pursue this particular subject in this correspondence," I will leave it for the consideration of your readers.

Dr. Nevins then assigns four objections to classing the fourteen subjected stations together and the fourteen unsubjected, and then comparing them as if they corresponded in every respect, except that one set is under the Act and the other is not, to which he complains I did not reply. It will be obvious, I think, to anyone accustomed to deal with the statistics of disease, who peruses my paper, that this needed no reply; but, as Dr. Nevins thinks otherwise, I will endeavour to meet his wishes.

The first objection is: "The stations differ so widely from one another that, for all other health purposes, Dr. Balfour divides them into eight separate classes in the Army Report, because they cannot be classed together." Dr. Balfour assigns the following as his reason for making the classification in question. "The number of men at many of the stations is so small that it would be obviously incorrect to draw conclusions as to the influence of the locality in inducing sickness from the results of so limited a period as a year. With a view to obtain data less liable to objection, we have classed a number of the stations together into the following groups" (Statistical Report for Army for 1860, p. 6). This clearly shows that the grouping was not made on the ground of well recognised differences among the stations, which prevented their being classed together, but in a tentative spirit, to ascertain from the aggregate of several years' observations of small bodies of men, under somewhat similar external conditions, whether they were influenced by these, and, if so, what conclusion the results would justify: a very different position indeed from that assumed by Dr. Nevins. In 1870, when, from the abolition of the depot battalions, the stations in group seven, where these had been quartered, were occupied by other troops, that was struck out, and Dr. Balfour redistributed the stations among the first, second, fourth, and eighth groups of the previous classification, to which they bore the greatest affinity.

Dr. Nevins's second opposition is: "The ratio of disease has been so widely different from the first in different stations as to make it impossible to compare them together; for example, 81 per 1,000 in Aldershot, and 126 per 1,000 in Dublin in 1866, before the Act was in force." There is no reason why the ratio at Aldershot should not be compared with that at Dublin, provided there be no attempt to draw conclusions from the premises which they do not support. We have the ratio per 1,000 of admissions into hospital for primary venereal sores at Aldershot and Dublin from 1864 to 1872 as follows.

Years	1864	1865	1866	1867	1868	1869	1870	1871	1872
Aldershot	105	100	81	81	77	63	67	65	62
Dublin	179	150	126	129	139	180	128	117	165

These two stations have different ratios of admissions it is true,

but both show a marked decline from 1864 to 1866; in 1867, the first came under the Act, and, thereafter, the admissions continue to decline with slight fluctuations; while the second, not having this measure applied, shows an increase in 1867, and in 1869 has as many admissions as in 1864, after which they decline to 1871, but increase largely again in 1872. These facts show that at Dublin the disease fluctuated considerably, presenting minima in 1866 and in 1871; while at Aldershot, where preventive measures were had recourse to after the minimum of 1866, instead of rising, as at Dublin, the new cases fell; and the natural inference is that this was the result of these measures limiting the spread of the disease. It is true no statistician would like to base his conclusions on a single instance, such as the above, but would avail himself of all the evidence within his reach bearing on the same point, to corroborate it or otherwise; but, if he found it all lead to the same conclusion, as is the case with that from the fourteen stations under, and the fourteen which have never been under, the Act, he would require evidence, very different from any Dr. Nevins has yet afforded, to satisfy him that he was in error.

Dr. Nevins's third objection is "the variable amount of disease in the large manufacturing towns which are all 'not' under the Act, compared with the military towns which are 'under the Act,' is shown by the extreme fluctuations of disease in one class of towns (up a hundred one year and down a hundred the next), compared with the other, long before the Act was passed—a characteristic difference which still continues, and makes comparison impossible." We have returns for Manchester from 1860, for Preston from 1861, and for Sheffield from 1864, but the primary sores are not indicated separately before 1864, the return previously including every form of venereal affection. Taking the primary sores from 1864 onwards, the greatest rise at Manchester in any year was 85 per 1,000 in 1867, the fall the following year being 62; at Preston the greatest rise was also 85 per 1,000 in 1869, the fall the ensuing year 58; and at Sheffield the greatest rise was 57 per 1,000 in 1867, the fall next year being 56. It is to be observed that from 1864 to 1872 the mean annual force in Manchester was only 995, in Preston 878, and in Sheffield 707; and if we refer to military towns, with a mean annual strength of 1,000 or less, we find at Maidstone, in 1867, a rise of 104 per 1,000 in the primary venereal sores, with a fall of 120 in 1868; at Windsor a rise of 78 per 1,000 in 1868, and a fall of 43 in 1869; at Fermoyle, in 1869, a rise of 69 per 1,000, and a fall next year of 27; at Limerick, in 1870, a rise of 82 per 1,000, and the following year a fall of 79; while the fluctuations from year to year at these stations are not less marked than in the manufacturing towns. There is no ground, therefore, for Dr. Nevins's belief that the fluctuations are greater in the manufacturing than in the military towns, where equally small bodies of troops are quartered, and the reply to his objection is a passage he quotes with approval from my communication to the *Medical Times*, viz., "no weight can be attached to the ratios of attacks for single years at small stations, when the whole or the greater part of the force employed may have belonged to a single regiment."

The fourth objection is that "the large ratio of fall in disease in the military towns, with the small fall in the manufacturing towns years before the Act was passed, showed the existence of some agency in the one set of places which did not operate in the other, quite independently of the Act, which was not in existence, and made subsequently comparison impossible. The continued reduction of disease is attributed by the opponents of the Acts to a continuance of causes operating before, whilst the advocates of the Acts claim the whole of the difference as the result of the Acts; as if there had been no substantial reduction in disease, and no notable difference in amount between the manufacturing and military towns before the Act was passed." It is admitted that primary, venereal sores decreased among the troops serving in this country from 131.8 per 1,000 in 1860, to 80.2 in 1866, but in 1867 they increased again at the stations where their progress was not interfered with by the operation of the Act; after some fluctuation they showed a second minimum in 1871, but presented a sharp rise again in 1873. As already stated, the details for different stations are not available before 1864, but from that year to 1873 the course of the disease is shown, for the fourteen stations which have now been under the Act in the following table, in which Manchester, Preston, and Sheffield are grouped together, and the remaining eleven stations by themselves. (See next page.)

It will be observed that the mean strength at the manufacturing towns was 2,580, while at the eleven other stations it was more than six times greater. This is an important fact to bear in mind, as it is found that, by aggregating a number of smaller stations, unusual prevalence of the disease at any one or more becomes neutralised by deviations in the opposite direction at others, and the resulting ratios per 1,000 are more regular, and give a much better and more trustworthy view to its progress. It has been already mentioned that the prevalence of primary

sores declined from 1860 to 1866, and the last column in the above table shows this minimum distinctly, followed by a considerable rise in 1867, and by a further one in 1869, after which it fell to the second minimum in 1871; there was a large increase again in 1872. If the column for the three manufacturing towns be taken, the minima of 1866 and 1871, with the rises in the ratio in 1867, 1869, and 1872 are equally distinct, as at the other eleven stations, though from the smaller strength at the former their fluctuations are more pronounced. The mean amount of diseases in the two groups, however, is much the same, being 108.5 per 1,000 in the manufacturing towns, against 113.1 in the eleven other stations. It is obvious, therefore, that the question of the influences

Years	Manchester, Preston, and Sheffield		Eleven other Stations not under the Act.		Ratio per 1,000 of mean strength	
	Strength	Primary Venereal Sores	Strength	Primary Venereal Sores	Manchester, etc.	Eleven other towns.
1861	2,381	216	17,693	2,239	90.6	127.2
1865	2,676	273	16,896	1,883	102.0	112.0
1866	2,255	292	17,500	1,714	89.6	99.1
1867	2,888	401	17,703	1,968	110.0	111.2
1868	2,826	295	16,690	1,845	101.1	110.1
1869	2,432	300	15,307	1,881	100.1	113.0
1870	2,331	228	15,521	1,791	97.8	111.6
1871	2,779	240	17,178	1,625	86.1	91.0
1872	2,665	271	17,295	2,183	105.2	126.2
Sums	23,224	2,522	151,653	17,153		
Average	2,580	280	16,850	1,906	108.5	113.1

which caused these variations in the frequency of the disease in the manufacturing towns, was not confined to them, but was experienced at many other places, both in this country and Ireland, and, in fact, it was apparent at nearly every one of the twenty-eight military stations, for which we have the detailed returns, up to the time of each coming under the provisions of the Act. This fact is directly opposed to the contention of the opponents of the Act, that the causes operating to reduce the frequency of the disease from 1860 to 1866 continued in force thereafter, and led to the reduction at the stations under the Act, for the evidence is to the effect that the disease became much more frequent all over the country, and the only places where its development was checked was the stations actually under the restrictions imposed by the Act. Apologising for the length to which these remarks have extended,

I am yours,

ROBERT LAWSON, Inspector-General.

London, March 26th, 1875.

SIR,—Mr. Ffolliott has discovered an error in my supposing that the seven months in his table meant seven months at Aldershot, instead of part only of that time being there and part in Colchester. It is the consciousness of my own liability to mistake in figures, and the many illustrations we have had of this liability in others, which has made me so urgent that only published and authenticated statistics should be used in this controversy; whilst the advocates of the Acts have, with scarcely an exception, confined themselves to unpublished and unauthenticated statistics, which it is impossible to check as Mr. Ffolliott has just checked mine. But, although he is entitled to score one in this detecting my error, he has not in the slightest degree touched the real question at issue. Dr. Parkes contended that twice the amount of syphilis in Parkhurst as in Portsmouth proved incontestably that the difference was solely owing to the absence of the Acts in Parkhurst. I replied, that both Colchester and Aldershot were under the Acts, and yet Mr. Ffolliott's regiment had far more than twice as much disease in one place as in the other, and therefore the absence of the Acts was not the cause of the difference in Dr. Parkes's case. It does not injure this argument to reply, that Mr. Ffolliott's regiment was in the same place all the time; for, if it had twice as much disease in one year as in another in the same place, and under the Acts all the time, it shows that the presence of the Acts does not prevent increase of disease in Colchester, or the absence of the Acts cause it in Parkhurst. This point Mr. Ffolliott's last letter leaves quite untouched.

His quotations about the *Excellent*, with which I was previously well acquainted, simply prove that the Acts, which have been in operation in Portsmouth for ten years, do not prevent the influx of diseased men there, and therefore an increase of disease amongst women, who repay it to another set of men; and that the "protection" the men require is that of their own self-control and abstinence from evil, and not that of a Contagious Diseases Act. If any proof of this be desired, we have only to turn to the Army Statistics for London, which show that the amount of syphilis is habitually from two to five times as much

among the Foot Guards as in the Household Cavalry, though both are equally without "protection", and are equally exposed to temptation and danger.

I do not understand the last paragraph of Mr. Ffolliott's letter; for it is Dr. Balfour's returns that I have referred to throughout, and called upon the advocates of the Acts to refer to, instead of their own picked and unauthentic statistics. If Mr. Ffolliott had taken the trouble to read my reply to Mr. Lawson, he would have seen why the opponents of the Acts object to Dr. Balfour's clubbing together the fourteen stations under the Acts, and the fourteen not under them, in the table to which he alludes. And those objections have not yet been answered.

I am, sir, faithfully yours,

J. BIRKBECK NEVINS, M.D.

Liverpool, March 31st, 1875.

P.S.—In his letter of April 3rd, Dr. Parkes does not add to his former arguments in favour of his Chatham regiment, and I have nothing to add myself. The profession has now the arguments on both sides, and must form its own judgment. I must, however, allude to his objection to my omitting the year 1874 from my diagram, on account of the new Army Regulations. He says:—"Neither he (Dr. Nevins) nor I, nor any other man, knows with certainty whether the new regulation of 1873 had any effect; and there is, therefore, no evidence on which this year can be excluded." Dr. Parkes himself, in his original letter, suggested the doubt that this new regulation threw upon the figures for 1874, and I could not anticipate after that he would claim the reduction in 1874 as clearly belonging to the Acts. I may further refer him to a leading article in the *BRITISH MEDICAL JOURNAL* of November 22nd, 1873, page 610, headed "Army Medical Grievances", in which the following occurs; the article being evidently written by a well informed man. "One word, in conclusion, on the operation of the new regulations for hospital stoppages at Aldershot. Venereal diseases have fallen greatly in number, but the druggists' shops are crowded with soldiers applying for treatment, whilst the cases taken into hospital are frequently far advanced. . . . So that it is evident we can no longer place any faith either in statistics regarding the amount of syphilis, or in reports on the working of the Contagious Diseases Acts in our military stations." On this point also, the profession has now the opinion on both sides, and will judge whether the fall in the Chatham regiment in 1874 ought to have been included in the diagram or not.

SIR,—This garrison town is under the Contagious Diseases Acts. The strength of the 10th Brigade Royal Artillery, stationed here, is 650; deduct, however, 68 for men married with, and 60 for men married without, leave, and there will remain 522 single men. Since January 1st, there have been but six cases of gonorrhœa which were contracted here, and only one of primary syphilis, which, however, was contracted in Ireland; so that there has actually been not one case of primary syphilis, contracted in the place, admitted into hospital, out of a body of over 500 men, during a period of fifteen weeks.

Comment is not required; but, by way of contrast, I will relate what occurred to a company of artillery 1855, which was then stationed here. The strength was about 100; 36 were in hospital at one time with venereal complaints, and consequently so reduced the number of men fit for duty, that another company was ordered from Falmouth to take up the duties.—I am, sir, yours faithfully, E. J. HORWOOD, Devonport, April 14th, 1875. Surgeon-Major, R.A.

DR. SANDERSON'S SPEECH ON THE GERM-THEORY OF DISEASE.

SIR,—I hope that no one interested in the discussion concerning disease-germs will allow himself to be prejudiced against my views by the remarks made by Dr. Sanderson, at least until Dr. Sanderson shall have more fully explained the objection he characterises as "insurmountable", and an opportunity shall have been afforded me of replying.

Great authorities named by Dr. Sanderson, if pressed for an opinion concerning a germ-theory, would, according to him, "shrug their shoulders", and in this way, I suppose, annihilate the theory in particular, and make an end of the persons who entertained it. The members of the Pathological Society, however, "ought not to shrug their shoulders" in the presence of a few of the "facts" advanced by Dr. Sanderson.

For my part, I object entirely to scientific questions being settled by shrugging of shoulders; but, if I were a great scientific authority, and allowed myself to indulge in the exercise of that privilege, I should shrug my shoulders very much at some of the "facts" mentioned by Dr. Sanderson, more at some of the conclusions he has deduced, and most of all at the coolness displayed by him and a few other scientific

authorities in ignoring or in authoritatively disposing of the scientific work and conclusions of other Englishmen whose scientific position is not inferior to their own. I am, sir, your obedient servant,
London, April 12th, 1875. LIONEL S. BEALE.

THE EXAMINATION IN ARTS AT THE APOTHECARIES' HALL.

SIR,—On Friday and Saturday, January 29th and 30th last, the usual examination in arts was held at the Apothecaries' Hall. At the top of the first-class of the pass-list was placed Charles Matthias Lamb, and his certificate was shortly afterwards sent him in the ordinary course.

The Society of Apothecaries afterwards received information which led them to believe that Charles Matthias Lamb was not present himself on either of the days of the examination in question, and that he was, in fact, personated by some one else who answered the examination paper for him.

I communicated the suspicions of the Society to Charles Matthias Lamb accordingly, and required him at once to deliver up the certificate, which had been, as the Society believed, improperly obtained, so that the same might be cancelled. The certificate was returned to me the next day. The suspicions entertained by the Society having been hereby confirmed, it seems to be their imperative duty towards the members of the medical profession in general, and the students in particular, that these facts should be most generally known and widely circulated.—Your obedient servant, R. H. ROBERTSON,

Secretary to the Court of Examiners in Arts.

Apothecaries' Hall, London, E.C., April 13th, 1875.

MORTALITY OF CHILDREN.

SIR,—I notice in your number of April 3rd, a paragraph to the effect "that the mortality of children is highest in hot weather in Australia". I do not think we are to conclude that it must necessarily be the case in our country, for our temperature now reaches the height given at Melbourne in January last.

It may be interesting for you to know that in February I had to record an unprecedented mortality rate of 33.3 per 1,000, and this occurring in a rural district. The number of deaths amounted to 130; and out of this number, 52 were children under 12 months, and 79 under 5 years; the percentage, therefore, of children under one year, would be 40 on the total deaths, and 60.7 per cent. on children under 5 years. These averages are considerably above any that I have had to chronicle in warm or any other season of the year.

For comparison, I should be glad if you could obtain the percentage of Dr. Mitchell's cases, and also up to what year does he designate "children".—I am, yours truly, E. R. MORGAN,

Medical Officer of Health, etc.

Neath, Glamorganshire, April 7th, 1875.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Thursday, April 8th.

Proposed Fever Hospital.—Captain RITCHIE presented a petition, signed by 10,688 persons, praying that permission should not be granted for the erection of the proposed fever hospital at Hampstead.

Loans for Artisans' Dwellings.—The CHANCELLOR of the EXCHEQUER informed Sir S. Waterlow that the Public Works Loan Commissioners had lent or promised the whole of the £250,000 which they were authorised to deal with by the Act of 1866. The Government intended shortly to introduce a Bill for the purpose of raising more money for the commissioners for the erection of dwellings for the labouring classes, and for other objects.

The Pollution of Rivers.—Mr. SCLATER-BOOTH, in reply to Mr. Kay-Shuttleworth, said he hoped to be able next week to introduce the Bill for the prevention of the pollution of rivers.

Monday, April 12th.

Artisans' Dwellings Bill.—In the committee on the Artisans' Dwellings Bill, clause 7, which relates to the duty of the local authority in carrying schemes when confirmed into execution, occupied several hours. The point chiefly discussed was the imperfect obligation on the local authority to go forward with its scheme.—Mr. FAWCETT, who spoke repeatedly on the topic, insisted that there was nothing in the clause to compel a local authority to build up after it had pulled down, and Sir SYDNEY WATERLOW proposed an addition to the clause, which would have given to the confirming authority power to compel the local authority to go on. He was supported by Mr. DODSON and Mr.

TORRENS, who assured the House that overcrowding could not be checked by pulling down streets, and warned the Home Secretary that "Haussmannising Paris had led to the Commune".—Mr. CROSS opposed the proposal, expressing perfect confidence that the confirming authority had already sufficient power to compel the local authorities to go through with their schemes. On a division, the amendment was negatived by 137 to 48.—Mr. FAWCETT subsequently returned to the point, and proposed that, if at the end of three years the local authorities be unable to let the uncleared plots, the obligations imposed by the Act shall cease and determine.—Mr. CROSS opposed the amendment, declaring that Mr. Fawcett's aim was to convert the Bill into a Towns Improvement Bill, which was not the intention of the Government.—Mr. KAY-SHUTTLEWORTH also opposed the amendment, and on a division, it was negatived by 211 to 43. Clauses up to 13 were agreed to without debate. On clause 13, which relates to the acquisition of lands, Mr. JACKSON was anxious to substitute the Lands Clauses Consolidation Act for the machinery of the clauses, but this last was so decidedly preferred by Mr. Gibson, Mr. Herschell, and others, that Mr. Jackson withdrew his amendment. At clause 15 the further progress of the Bill was adjourned.

Wednesday, April 14th.

Medical Acts Amendment (College of Surgeons) Bill.—This Bill passed the second reading.

MILITARY AND NAVAL MEDICAL SERVICES.

MOVEMENTS OF ARMY MEDICAL OFFICERS.—Surgeon G. Atkinson, Army Medical Department, has joined at Aldershot, and is ordered to do duty with the second Station Hospital until further orders.—Surgeon H. Scott has been attached for duty to the Station Hospital, Phoenix Park, until further orders.—Surgeons F. A. L'Estrange and F. Johnson have been ordered from Gort and Dunmore to Dublin for duty till further orders.—Surgeon-Major T. Murray, in medical charge of the 10th Regiment Madras N.I., is allowed furlough to Europe for two years from date of departure.—The following orders are confirmed in the Bengal Medical Service. The Allahabad Divisional Order, dated February 16th, 1875, directing Surgeon W. E. Battersby, M.B., to make over medical charge of the 1st Bengal Cavalry to Surgeon A. Deane, of the 35th N.I., and proceed without delay to Rawul Pindee, reporting himself for duty to the deputy surgeon-general, Indian Medical Department, of that circle. Gwalior District Order, dated February 12th, 1875, directing Surgeon G. C. Hall, 17th N.I., to proceed to Jhansee to relieve Surgeon H. J. Linton of the medical charge of the 24th N.I. Allahabad Brigade Order, dated 17th February, 1875, directing Surgeon T. J. Gallwey, M.D., and F. S. Young, M.B., recently arrived from England on first tour of service in India, to remain on general duty at that station until further orders.

RETIREMENTS.—After a service of forty-years, Surgeon-General J. C. Brown, C.B., head of the Bengal Medical Department, will accept retirement at the end of the year. He has been surgeon-general since November 1870, and was appointed an honorary surgeon to her Majesty, September 6th, 1861. The latter appointment will be retained on his retirement.—Surgeons-Major H. Wakefield and H. J. Gane, Bombay Medical Service, are about to retire. Surgeon-Major Wakefield joined the service on February 14th, 1855, and was promoted surgeon-major February 14th, 1867. Dr. Gane was appointed assistant-surgeon March 20th, 1853, and became surgeon-major March 20th, 1873.

OBITUARY.—Inspector-General A. S. Macdonell, on the half-pay list, died suddenly a few days ago at his residence in Bath, at the age of 70. The deceased officer became a hospital assistant, November 15th, 1827; assistant-surgeon, July 29th, 1830; surgeon, December 2nd, 1842; staff-surgeon, March 28th, 1854; deputy inspector-general, February 1st, 1855; and honorary inspector-general on the half-pay list, June 1st, 1859. He served with the 80th Regiment at the Sutlej campaign of 1845-46, including the battle of Moodkee, Ferozeshah, and Sobraon (medal and two clasps). He was also in the Crimea from September 17th, 1854, and received medal and clasps, 4th class of the Medjidie and Turkish medal. An inquest was held on the body. The only evidence taken was that of Miss Saunders, an adopted daughter, who stated that the deceased died in her presence. He had been an invalid for several years from rheumatic gout, but his death was altogether unexpected. Deceased had not taken medical advice for two years, and did not think himself seriously ill. Just previously to his death, he complained of pain in the chest. A verdict of death from natural causes was returned.

THE DUTIES OF ARMY MEDICAL OFFICERS.

WE receive from time to time letters from army medical officers, complaining of the amount of the duties which they are called upon to perform. Individual medical officers have charges which until lately were divided between two or more medical officers. The official returns they have to prepare are numberless. Leave to quit their posts, even for a day, cannot be obtained, as there are no medical officers available, so they are informed, to take their places during their absence. Hence it is inferred that the department is shorthanded, notwithstanding the statement of the Secretary of War, that there are no vacancies in it. If we do not bring these complaints separately to notice, it is because we feel how impossible it is for them to be sifted and dealt with satisfactorily in the pages of the JOURNAL. When we turn to an Army List, we see the names of 940 medical officers in the Medical Department, and among this large number we know that variations from sickness, death, retirements on temporary and permanent half-pay, and other casual occurrences, must be constantly happening to disturb existing arrangements. It is for the Director-General of the department to make the best distribution of the officers he can, and also to arrange for casualties as they occur, so that the duties may be as fittingly and fairly divided as practicable; and we must trust that he does so to the best of his judgment and ability. We are bound to suppose that, if the department were in his opinion shorthanded, if the duties appeared to him to press unduly on the medical officers under his direction, he would represent the necessity for an increase of the numbers in the department to the responsible minister. The Secretary of State for War must be advised on this subject by the Director-General of the medical service of the army; and, when he states in the House of Commons that there are no vacancies in the Army Medical Department, it must be taken for granted he states so on information supplied to him that the numbers required for its working are complete.

We wish we could see signs of a satisfactory settlement of the more general sources of discontent in the Army Medical Service. A military cotemporary, in an article on the subject, while admitting the existence of much discontent among the medical officers, has lately stated that there never was known a time when they were not discontented. But surely, if discontent be so marked in one particular branch of the army, and if this discontent be not confined to the officers of this or that period in it, the presumption is, that there must be some solid grounds for it. But we maintain that there was no general discontent in the department until the articles of the Royal Warrant of 1858 had been gravely tampered with. When rights and privileges which were distinctly conferred in that warrant were found to be systematically ignored, at first on secret instructions, and were subsequently openly withdrawn by published orders and warrants, general discontent was naturally engendered, and no wonder it has never ceased since. Would the combatant officers of the army have rested content had a Royal warrant affecting their interests been similarly tampered with? The writer of the article above referred to seeks to show the groundlessness of the prevailing discontent in the Army Medical Department, by comparing the pay and allowances of young medical officers in the army with the salaries of assistants to civil medical practitioners and of the surgeons to county infirmaries and workhouses. When the circumstances, risks, and responsibilities of the two sets of medical practitioners resemble each other more closely than they do at present, we may think it worth while to discuss the question of their relative remunerations; but, until they do, we can only suppose that our cotemporary, by setting up such an argument, feels, and cannot help exposing, the weakness of the position he has taken upon himself to maintain.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

THE guardians of the Axbridge Union have increased the salary of Dr. Thomas McClure, medical officer of No. 2 district from £30 to £50 per annum, and fees.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

LOUTH.—Scarlatina which, during the past year was so prevalent in various parts of the kingdom, was also epidemic in the Louth Union, and, according to Dr. Domenichetti's report, still continued in a fatal form at the early part of the present year. A good deal of it was imported from other districts, especially from Great Grimsby, and it

was spread into the various villages of the district. In several instances, under the influence of isolation and of disinfection, the latter being carried out on a proper system from thirty central stations, the disease was prevented from spreading, but the difficulty of arresting such a disease in the absence of hospital accommodation, leads Dr. Domenichetti strongly to advocate the establishment of cottage hospitals. There is at present a good deal of overcrowding, which tends so strongly to the further spread of zymotic diseases, but special instances are recorded in which owners of property have shown promptitude in building new cottages on receiving an intimation from the sanitary authority as to its necessity. With regard to the general disposal of filth, Dr. Domenichetti speaks strongly in favour of the ash-closet, which he considers preferable to any other form in villages; and, with a view of dealing with the liquid refuse, he has rather opposed schemes of drainage, but has encouraged the plan of dealing with each house separately, by the construction of tanks, having means of overflow into the gardens. The tanks require constant supervision; but, when they receive proper attention, they are stated to be suitable for districts in which isolated houses preponderate.

TAUNTON.—In the rural portion of this district, there has been amelioration in the general sanitary conditions, but many evils still remain to be dealt with. The privies are a source of nuisance, their contents percolate into adjoining wells, and if there be a stream near at hand, it also is sure to be polluted. The question of the overcrowding of cottages, which is referred to in almost every report which comes under our notice, and which is evidently one of the greatest and the most prominent sanitary evils of the present day, is dealt with by Dr. Alford; but the remedy is stated to be difficult, for the alternative in many cases seems to lie between an overcrowded and dilapidated dwelling on the one hand, and the workhouse on the other. The difficulty which there has been hitherto of procuring means of isolation is in course of removal by the joint action which has been determined on between the urban and the rural districts of Taunton, in the construction of a hospital, and it is to be hoped that in connection with it both a mortuary and proper disinfecting apparatus will be provided. In the town of Taunton, sanitary improvements have also been effected, the sewage which previously poured itself at several points into the river Tone, has now been brought to one point, with the object of dealing with it either by precipitation, irrigation, or filtration. Additional means of sewer ventilation are also being provided; but it is evident that the new ventilators require more frequent supervision, to prevent them from being blocked up by road detritus, and hence rendered altogether useless. One very great evil, however, remains in Taunton, for a considerable number of the population still derive their water supply from surface wells, a source of supply which is utterly unsuited to urban populations. The consequence is that the water is seriously contaminated, and so thoroughly is the soil surrounding some of the wells contaminated with filth, that in some instances, after these have been pumped out and cleansed, the fresh supply has been found to be as bad as, if not worse than was the first. There is a wholesome public water supply in the town, but it is to be regretted that it is not delivered on the constant system.

PORTSMOUTH.—Mr. Turner's report on the sanitary condition of the borough of Portsmouth during the past year has, like its predecessor, been prepared with considerable care. The death-rate has been 20.8 per 1,000, which is somewhat higher than that which obtained last year, but which is decidedly below the average for the towns of England. Portsmouth still claims the right to maintain its boast of having a low general death-rate, and if Mr. Turner's statistics, which tend to show that the comparatively small mortality is not due to the number of soldiers and sailors in the town, are accepted, the claim must be allowed. In his opinion, the remunerative occupation which between 5,000 and 6,000 people find in the healthy and well-regulated workshops of the dockyard, and also the comparatively warm and equitable temperature of the town, have most to do in maintaining health and reducing the death-rate. Great care is stated to be taken against the spread of infectious diseases in the town. The medical officer of health receives returns of sickness from the poor law medical officers, and the School Board forward him the names of all sick absentees, a plan which has often been of the greatest advantage in preventing such diseases as measles and scarlet fever from spreading in the schools. But there are no proper means for isolating the sick of infectious diseases in Portsmouth, and Mr. Turner considers that the escape of the town from any epidemic has to a great extent been due to good fortune. Thus, when scarlet fever appeared last year, it happened first to attack the children of soldiers in the Eastney Barracks, and although there were in all 58 patients, yet owing to the existence of an infectious disease hospital in

the barracks, the further spread of the disease was prevented. As a further example of what such institutions can do, the case of Rugby is adverted to. In that town small-pox was fatally prevalent last year, and a wooden hospital was constructed as quickly as circumstances would allow; it was completed in fourteen days, and thirty patients were admitted. Here the outbreak ceased, and although the cost of the hospital was about £2,000, yet, as Mr. Turner points out, the epidemic of small-pox in Portsmouth in 1872 was far more costly. Besides which, Rugby now possesses the means of staying future epidemics. The report next deals with the water supply, which is by no means so satisfactory as it might be made, and it particularly urges the necessity of a continuous supply. The present supply is very intermittent, and experiments have shown that during the periods of intermission, the suction from without is such that basins of water held at the mouth of open taps are at once emptied of their contents. The water supply is also often drawn from water-closet, cisterns, and there are facilities for the suction of foul air into the pipes. A chapter is next given to the sewage of the town, and the necessity for the provision of ample means of sewer ventilation, and for enforcing compliance with the existing bye-laws, as to the proper and efficient trapping of house connections, is specially referred to. A number of tables, explanatory of the prevailing mortality, and well-coloured diagrams, showing the meteorological conditions of the past year, are appended.

THE WATER-SUPPLY OF THE CITY OF LONDON.

THE recent startling report of Dr. Sedgwick Saunders upon the condition of the water-supply in the courts and alleys of the City has, to the credit of the City Commissioner of Sewers, been promptly acted on. At a meeting held at the Guildhall, March 31st, it was proposed by Mr. J. T. Badford that the erection of the stand-pipes, ordered by the Commissioners in November last, but subsequently postponed, be forthwith proceeded with. It was pointed out by Mr. Haywood, the engineer, that the total cost of the stand-pipes would not exceed £1,475, and it was also stated that the New River Company had promised not to charge anything for the additional supply, and further, that the cost of maintaining the stand-pipes would be trivial. Some discussion and explanation took place as to the cause of the delay that had arisen in carrying out this reform. It appears that the Gas and Water Committee of the City Corporation have for some time been considering the advisability of erecting hydrants throughout the city, in order to secure better protection against fire, and it appeared probable that the provision of stand-pipes would form part of their scheme. The proposal of Mr. Badford met with general and cordial support, and was, in the end, unanimously adopted, orders being given for the immediate execution of the work. It would be well indeed if all sanitary authorities were as prompt and unanimous in acting upon the reports of their health officers as were the City Commissioners of Sewers on this occasion.

PAYMENT OF UNION MEDICAL OFFICERS.

A CORRESPONDENT writes to us: "At the present time, when the necessities of life have become more expensive, and the value of money much less than it used to be, it would be well if medical men everywhere would do as the profession in Gravesend and Milton have done, in order to obtain for the Union Medical Officers an increase in the amount of salary they are receiving. In this town there are two districts, one of Gravesend and the other of Milton, each with its own medical officer taking charge of it, and of those patients in the house who belong to and are sent in from their respective districts. This arrangement has met with the approval of the local government inspectors, who think it likely to prevent the uncomfortable feeling which sometimes exists when the officers having the charge of the in- and out-patients are not the same; the out-door surgeon being, it is thought, likely to try to get rid of troublesome cases by sending them into the house, and the in-door surgeon being as anxious to keep them out. For the whole of these duties here, they each received the magnificent sum of £70 per annum. On the resignation of one of these gentlemen, the whole profession of the two districts sent in a memorial to the guardians, expressing their feeling that the sum of £100 per annum was but a moderate amount to be given for the duty in each district with its share of the house, and declining to come forward as candidates at a less salary. If there were the same *esprit de corps* in every Union, the profession would not be disgraced by the paltry salaries that are offered, as it is now. The guardians, however, in the first instance, advertised it at the old rate, and received but one application, which they, for some reason or other, did not accept. They then issued another advertisement, with the offer of an additional £15, making the salaries £85

each, and found a more acceptable applicant, whom they elected. A copy of the memorial was sent to this gentleman, with a postscript, in which he was informed that, if he accepted office on terms which the medical men within the district of the Union had one and all rejected, he could hardly expect, when he came among them, to have the right hand of fellowship held out to him by a body of gentlemen, one of whom would doubtless accept the office if the terms were such as they had considered fair and reasonable. He then, to his honour be it told, immediately withdrew, and left the guardians again to their own resources. These gentlemen were very angry, and with loud eulogies of 'Trades Unionism', etc., appointed the first applicant, who accepted the appointment, but, after a few weeks' sent in his resignation, and left it again unfulfilled. It is to be hoped that they will find the profession as united without the Union as it has proved itself within it, and that no medical man will come forward as a candidate for an office which a local practitioner would accept if a salary which is thought a reasonable and fair one, but by no means excessive, were conceded."

POOR-LAW MEDICAL APPOINTMENTS.

LYALL, W. L., M.D., appointed Parochial Medical Officer and Public Vaccinator for the Parish of Campsie, Stirlingshire, *vice* A. T. Wilson, L.F.P.S.G., resigned.
WELSH, Joseph, F.F.P.S.Glas., appointed Medical Officer and Public Vaccinator for the Brampton Brian District of the Knighton Union, Radnorshire, *vice* H. O. Brown, M.R.C.S. Eng.
WHEATCROFT, S. H., Esq., appointed Medical Officer for the Sixth District of the Easington Union, *vice* E. A. Piggott, Esq., resigned.
WOSKEY, J., M.R.C.S., appointed Medical Officer to the First District of the Hatfield Union.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed their primary examinations in anatomy and physiology at a meeting of the Court of Examiners on the 9th inst., and, when eligible, will be admitted to the pass-examination:

Messrs. Robert F. Cumming, William L. Heath, J. N. Legge Paulley, George O. Mead, Thomas E. P. Prideaux, and Henry F. Steele, students of St. Bartholomew's Hospital; Thomas C. Nugent, John Poland, Jeremiah Reader, George Mackern, and George A. Wright, of Guy's Hospital; Herbert Flaxland, George C. Henderson, Charles E. Beever, and Howard Cane of University College; Charles G. Dalton, William A. Bertrize, and Thomas W. Richardson, of the London Hospital; Edward Keen, D. George Allen, and George Walker, of St. George's Hospital; George H. D. Gimlette, and Herbert U. Smith, of St. Thomas's Hospital; William J. W. Prosser, and John Gabe, of the Middlesex Hospital; Johnson Symington, of the Edinburgh School; Samuel E. Martin, of the Belfast School; Daniel Colquhoun, of the Charing Cross Hospital; John B. Coumbe, of St. Mary's Hospital; Thomas F. H. Smith, of King's College; and Charles C. Lagage, B.A. Cantab., of the Leeds School.

The following gentlemen passed on the 12th inst.:

Messrs. Edmund J. Thompson, Boyd B. Joll, Joseph E. Bullock, Francis A. Jeans, and John D. Evans, of University College; George A. Madin, Thomas F. Hayward, Thomas B. Carlyon, John F. Duncan, and David A. Hughes, of St. Bartholomew's Hospital; William A. S. Walsh, Charles W. Gay, and William R. White, of King's College; John M. Grimmer, and Herbert H. Tidwell, of St. George's Hospital; William H. Battle, and Richard F. Bell, of St. Thomas's Hospital; Robert S. Wainwright, and Owen Bowen, of Guy's Hospital; William C. S. Bennett, and Charles W. Sharples, of the Middlesex Hospital; George Eliot, of the Westminster Hospital; Arthur Greenwood, of the Charing Cross Hospital; Arthur B. Prowse, of St. Mary's Hospital; and Harold L. Palmer, of the London Hospital.

Out of the 180 candidates examined, 35 having failed to acquit themselves to the satisfaction of the Court of Examiners, were referred to their anatomical and physiological studies for three months. The General Medical Council having nominated Dr. Fleming of Glasgow, and Dr. Barton of Dublin, to visit and report on the examinations, these gentlemen were in attendance all day on Monday, and took copious notes.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 8th, 1875.

Bernays, Herbert Leopold, H.M. Deekyard, Chatham.
Brent, Mortimer John De, Marischal Road, Lee.
Friggs, Harry Buchan, Oncombe House, Havercastle.
Coles, John William, Camberwell New Road.
Donohoo, Thomas Bradford, Blackfriars Road.
Sandford, Robert Trotman, New Ormond Street, Bedford Row.
Twining, Alfred Hughes, Walthamstow, Essex.

The following gentlemen also on the same day passed their primary professional examination.

Cundell, George Richard, St. Mary's Hospital.
Davis, Frederick Howard, St. Bartholomew's Hospital.
Mathias, James, St. Bartholomew's Hospital.
Moore, Charles Arthur, St. Bartholomew's Hospital.
Smith, Rowland Dunn, London Hospital.

MEDICAL VACANCIES.

THE following vacancies are announced:—

- ABINGDON UNION—Medical Officer for the Workhouse. Salary, £45 per annum.—Medical Officer for No. 2 District. Salary, £115 per annum. Applications on or before the 24th instant.
- BARTON-UPON-IRWELL UNION—Medical Officer for the Cadishead District. Salary, £25 per annum.
- BETHLEM HOSPITAL—Two Resident Medical Students.
- BOLTON UNION—Medical Officer for the Ilkley District. Salary, £30 per annum.
- BRADFORD INFIRMARY AND DISPENSARY—Physician. Applications to be sent on or before June 12th.
- BRADFORD MEDICAL AND ASSOCIATION OF FRIENDLY SOCIETIES—Surgeon. Salary, £200 per annum, with fees, house, gas, etc. Applications on or before the 21st instant, to Mr. W. B. Cawthra, 18, Newington Street, City Road, Bradford.
- BURTON-ON-TRENT UNION—Medical Officer for the Etwell District. Salary, £70 per annum. Applications on or before the 19th instant.
- CHILTERNHAM GENERAL HOSPITAL AND DISPENSARY—Honorary Medical Officer at the Branch Dispensary. Applications on or before the 17th instant.
- DOVER HOSPITAL AND DISPENSARY—Resident Medical Officer—Salary, £90 per annum, with furnished apartments, coals, light, and attendance. Applications on or before the 20th instant.
- DOVER UNION—Medical Officer for the St. Mary's District and the Workhouse. Salary, £180 per annum.
- DROITWICH UNION—Medical Officer for the Droitwich Rural and Urban Sanitary Districts. Salary, £150. Applications on or before the 20th instant.
- DUNDEE ROYAL INFIRMARY—Resident Medical Superintendent. Salary, £200 per annum, with board, lodging, and washing. Applications on or before the 21st instant.
- GRAVESEND AND MILTON UNION—Medical Officer for the Milton District. Salary, £70.
- HARDINGSTONE UNION—Medical Officer for the Brafield District. Salary, £45 per annum. Applications on or before the 17th instant.
- HULL BOROUGH ASYLUM—Resident Medical Superintendent. Salary, £350, with coals, gas, washing, and vegetables. Applications on or before the 24th instant.
- KENT AND CANTERBURY HOSPITAL—Assistant House-Surgeon and Dispenser. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 30th instant.
- KILCHREHAN AND DALRICH, Parish of—Salary, £80 per annum. Applications on or before May 1st, to the Chairman of the Local Board.
- LIVERPOOL DISPENSARIES—Assistant Resident House-Surgeon. Salary, £105 per annum, with furnished apartments, coals, gas, and attendance. Applications on or before the 25th instant.
- MILFORD UNION, co. Donegal—Medical Officer for the Ramelton Dispensary District. Salary, £100 per annum, and fees.
- NEWBURY UNION—Medical Officer for the Fifth District.
- NEWMARKET UNION—Medical Officer for Nos. 1 and 3 Districts. Salary, £85 per annum.
- ROYAL INFIRMARY FOR WOMEN AND CHILDREN, Waterloo Bridge Road—Physician.
- ROYAL LONDON OPHTHALMIC HOSPITAL—Clinical Assistants and Ophthalmic Dressers. Applications on or before the 27th instant.
- ST. GEORGE'S AND ST. JAMES'S DISPENSARY—Accoucheur and Surgeon. Applications on the 29th instant.
- SALFORD AND PENDLETON ROYAL HOSPITAL—District Surgeon. Salary, £80 per annum, with board and lodging. Applications on or before the 21st instant.
- SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.
- SLIGO UNION—Medical Officer to the Workhouse. Salary, £100 per annum, and £10 as Sanitary Officer. Applications on or before the 20th instant.
- STOUBRIDGE RURAL AND URBAN SANITARY DISTRICT—Medical Officer of Health—Salary, £50 per annum. Applications on or before the 24th instant.
- TORREY INFIRMARY—House-Surgeon. Salary, £100 per annum, with board and lodging.
- TORONTO ASYLUM, Canada—Medical Superintendent. Salary, £411 per annum, with furnished apartments, fuel, light, and furnished table for family. Applications on or before May 15th.
- WEST DERBY UNION—Medical Officer for the Walton Workhouse.
- WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL—House-Surgeon. Salary, £100 per annum, with board, washing, and furnished apartments. Applications on or before May 3rd.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

- SHAPTER, Lewis, B.A., M.B. Cantab., appointed Consulting Physician to the Worsford House Hospital for the Insane, near Laxey, *vice* Thomas Shapter, M.D., resigned.
- SHREVEN, Alfred, M.D., appointed Physician to the Farringdon Dispensary.
- SMITH, Winckworth T., M.R.C.S. Eng., appointed House Surgeon to the Clinical Hospital and Dispensary for Children, Manchester, *vice* W. J. Sinclair, M.B., resigned.
- *STARKS, Edward I., M.B., M.R.C.P., appointed Physician to the Royal Infirmary for Children and Women, Waterloo Bridge Road, *vice* J. Williams, M.D., M.R.C.P., resigned.
- THOMAS, Jabez, L.R.C.P. Ed., appointed Surgeon to the Swansea Hospital, *vice* A. Davies, M.R.C.S. Eng., resigned.
- THOMPSON, Edward C., M.B., appointed Surgeon to the County Tyrone Infirmary, *vice* Henry Thompson, M.D., resigned.
- THORNEY, John G., M.D., appointed Physician's Assistant to the Bristol General Hospital, *vice* F. G. Stevens, M.R.C.S. Eng., resigned.

OPERATION DAYS AT THE HOSPITALS.

- MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- TUESDAY.....Guy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.
- WEDNESDAY..St. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.
- THURSDAY....St. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.
- FRIDAY.....Royal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.
- SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

- MONDAY.—Medical Society of London, 8 P.M. Dr. Pedler, "On the Pneumatograph"; Dr. Richardson, F.R.S., "A further Report on the Treatment in *extremis* of Cases of Fibrinous Separation within the Heart and Great Vessels".
- TUESDAY.—Pathological Society of London, 8.30 P.M. Adjourned Debate on the Germ-Theory of Disease; being a Discussion of the Relation of Bacteria and Allied Organisms to Virulent Inflammations and Specific Contagious Fevers.
- FRIDAY.—Clinical Society of London, 8.30 P.M. Dr. Gustavus Fritzsche of Poland (communicated by Dr. Tilbury Fox), "Case of Fibroma, weighing 35 lbs., successfully removed"; Mr. T. Smith, "Disordered Nerve-Function in an Infant"; Mr. R. W. Parkes, "Case of Scald of the Glottis, with deposit of False Membrane in the Pharynx, Larynx, and Bronchi"; Dr. T. Henry Green, "Acute Fatty Degeneration of the Heart"—Quekett Microscopical Club, 8 P.M. Dr. Daniel Moore, "Remarks on *Bucephalus Haimaeus* and an allied unnamed Form".

NOTICES TO CORRESPONDENTS.

- CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.
- PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with Duplicate Copies.
- AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.
- CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.
- WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.
- COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

INQUIRER (Eristol) states the clinical fact without any of the characteristic details, especially those of temperature, duration of the disease, and anatomical characters. In the present form, his question cannot properly be answered. Any answer would be a mere guess.

SPINA BIFIDA.

SIR,—As cases of spina bifida generally prove fatal at an early period of life, it may not be uninteresting to mention that I knew a case in the poorhouse at Zürich, shown me by my friend the late Dr. Herger in 1838, where the patient had attained the age of twenty-five years. I have never met with any record of such longevity. I think Sir Astley Cooper mentions a boy aged fourteen, in whom the tumour burst whilst bowing his hoop. In the case I mention, there was total paralysis of the lower extremities, a large tumour in the lumbar region, and cretinism. I often regretted my inability to make a sketch of the patient; and as then photography was not, I lost the opportunity of placing on record an immense number of valuable cases that came under my notice at a time when German literature was comparatively unknown. Albert Kölliker, whose name is known throughout the world, had just at my persuasion commenced his studies in physiology.—Your humble servant,
HENRY P. DRUMMOND, M.D.
Ipswich, April 1875.

AJAX.—John Rawson, who died in 1819, and to whose memory a tablet is raised in the parish church of Ecclesfield, Yorkshire, and described as a Fellow of the Royal College of Surgeons, could not have obtained that title from the London College, as the first batch was only made in December 1843; moreover, in searching the old list of members from 1800 to 1819, the year of his death, the name does not appear as holding the membership at College.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

ARMY MEDICAL REFORM.

SIR,—I do not usually take any notice of literary assassins who throw mud from behind the protection of a *nom de plume*; but if your correspondent "Statistic" had taken the trouble to read my pamphlet, he would have found at page 19, which precedes what he elegantly styles my "statistical vagaries," the following important reservation: "If, however, the data on which the calculation is made be correct—a qualification which was necessary, as the data were furnished to me by others. It is fortunate, however, for the cause of army medical reform, that the money cost of promotion at twelve years is immaterial to the main question at issue, as "Statistic" will find that promotion at twelve years is not asked for, as it would be useless to expect it; but promotion at fifteen years is hoped for at page 42.—Truly yours,

EDWARD HAMILTON.

120, Stephen's Green, April 7th, 1875.

P.S.—I think that, in attacking two individuals who have given their names fearlessly to the public, "Statistic" should have had the manliness to give his own.

THE CASE OF MR. HUGH REES OF LLANBERIS.

SIR,—I have been expecting to see some notice taken of the case of Mr. Hugh Rees of Llanberis, referred to in your issue of March the 27th. It seems to me that it would be but a proper and deserved appreciation of his conduct in resigning the post of surgeon to the Minorin Quarry, in consequence of a bone-setter being appointed to act in conjunction with him, if a subscription was started, and a purse presented to him by the profession. The sum collected would, perhaps, be most inadequate as a pecuniary recompense for the loss of a salary of £500 *per annum*, but I am sure Mr. Rees would be gratified by this mark of esteem from his professional brethren. I should be glad to give a small donation.

Yours faithfully, W. PUGIN THORNTON.

Devonshire Street, Portland Place, April 11th, 1875.

CREMATION (Torquay).—From the accounts of various travellers, the wealthy Chinese are burnt with great pomp, and their monuments are most curious and expensive.

CORONERS' INQUESTS.

SIR,—In the late unfortunate discussion relative to the duties of coroners, which appeared in the JOURNAL a few weeks back, I noticed a paragraph, drawing attention to the disparity in the percentage of inquests held in Hull and London, and expressing a desire to know why Hull held such a low percentage in comparison with other towns. As this low percentage of inquest would no doubt (if not explained) be made use of against those who conscientiously fulfil the duties for which they are paid, I beg to place before you a few facts, which will throw some light on our low rate, and show that ours is not exactly a model to be taken, but rather a system to avoid.

About two months ago, I brought the subject of the careless manner in which accidental deaths were passed over by our coroner before the Branch here: and, in support of the subject, brought forward the following cases as having occurred in my own practice within two years.

1. Mr. C., an engine-driver, aged 40, according to his wife's statement, never had a day's illness in his life. He left his work at midnight, and went to bed without any complaints as to his health. His wife awoke about 2 A.M., and found him dead by her side. I gave no certificate, and no inquest was held.

2. Mrs. H.'s child was found dead in bed. The child went to bed in good health. I gave no certificate; no inquest was held.

3. Mr. D., a man in lodgings, went to bed, suffering only from a cold, and was found dead in bed. I gave no certificate; no inquest was held.

4. Mr. W., a miller, got up at 6 A.M., apparently in his usual health, went into the mills, but soon returned, and shouted from the foot of the stairs, "I am dying!" Before his wife got down to him, life was extinct. In this case, a daughter had been sent to the asylum about a month before, and amongst the facts certified as showing her mental unsoundness were—"She had placed soap in her mother's beef-tea"; "she had placed liniment in her father's tea"; and, "she was constantly threatening to take their lives". About a fortnight before her father's death, she came out of the asylum, and two or three days after his death, we had to send her back to the asylum, on account of her increased threatenings and violence towards her mother. In this case, as in the others, the coroner gave a paper to the registrar (without any consultation with the medical man), saying he was satisfied as to the cause of death.

At the time I brought the subject forward, Mr. Atkinson, of this town, also mentioned to me several like cases which had occurred to him, on which no inquest or inquiry was held.

It is, perhaps, well we should remember that part of a coroner's duties is as much to distribute censure on those through whose careless oversight deaths are caused, as to convict of crime; and I think he fulfils his duties as properly in preventing careless handling of human lives, as in bringing criminals to justice. Regretting censure, which was ill-bestowed, on the new coroner for Middlesex,

I remain, yours truly,

W. HOLLDER.

Hull, April 6th, 1875.

* * The subject is one of much public importance. It would be interesting to have the experiences of other medical men, as to instances in which the want of medical knowledge of a coroner has led to errors or omissions of importance; and, on the other hand, illustrations of the value of medical knowledge by the coroner, in tracing the causes of disease and death. The object of the coroner's court is not to prove guilt against any.

A MEDICAL ARTIST.—The late Mr. Clift, F.R.S., the first Conservator of the Hunterian Museum, states in his diary (one as interesting to the members of the profession as that of Mr. Pepys to the general public), "of the Cartoon representing King Henry VIII presenting the Charter of Incorporation to the Company of Barber-Surgeons," that "the principal figure is very highly finished; several of the heads have been painted separately and inlaid in the background. It is esteemed to be the original from which the picture in the hall of the Barber-Surgeons Company, Monkwell Street, Cheapside, was painted by Hans Holbein. His initials and the date are upon the panel between the windows on the right hand side of this picture near the top. These became visible when the picture was cleaned in 1810." The more correct term would be monogram, thus H, a double H, for Hans Holbein. Perhaps this explanation may assist in clearing up your doubts; if not, inquire of Mr. Stone, of the College of Surgeons, who purchased, at the sale of his effects, the diary and interesting correspondence of the late Mr. Clift.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

THE ACTION OF ALCOHOL.

I VENTURE to ask for a corner of your JOURNAL in which to defend myself, and the more fully explain my views on the action of alcohol. In the first place, it appears that I am at issue with many members of the profession respecting the terms stimulant and narcotic. I contend that they are different in their actions, whether given in small, medium, or heavy doses; but others say that the finale of heavy doses of stimulant agents is narcotism. To this conclusion I demur. I have a friend very ill. Feeling extremely anxious respecting the case, I watch by the bedside night and day. I allow no sleep to my eyes, nor slumber to my eyelids—the excitement and the power of the will enable me for some time to sustain the continuous watching, until at length Nature is exhausted, and I sink overpowered with sleep. Such, I maintain, is not narcotism, or if it be, it is induced by the carbonic acid naturally present in the blood acting upon the exhausted frame. Now, mark the action of a true narcotic. I give opium; it does not stimulate the nerve-power away, but, so to speak, chains it down. The patient sleeps, not because the nerve-power is exhausted, but because it is narcotised. The nerve-power is still present, and only needs a stimulus to call it forth; hence, when a person is poisoned by opium, a cure can be effected provided the victim can be kept awake. Again, in narcosis from chloroform, the nerve-power is still there, as proved by the patient shouting when the knife is inserted in tender parts, and by the rapid recovery to consciousness after the chloroform is discontinued. This difference distinguishes the two classes of agents: the one induces stupefaction by exhausting, the other stupefies by directly narcotising the nerve-power. In your review of my essay on the subject, the reviewer draws my attention to the fact that a small current of galvanism increases the irritability of a nerve, that a stronger decreases it, and that a still stronger destroys its irritability, or *narcotises*. But does not this statement imply contradiction? Galvanism is a powerful stimulating agent, and while weak currents will induce the flow of nerve-electricity along any given nerve, and thus call into play the function of the part supplied by such nerve, stronger currents will exhaust or render powerless for a time, while very severe currents will completely exhaust and paralyse. Where the narcotism is, I fail to see. The nerve is powerless, because of the severe stimulation to which it has been subjected. Had it been narcotised, the currents could have been again induced by the galvanism. I think it will now be evident what I mean when I say that alcohol is a stimulant in all its doses. It stimulates to exhaustion, and when the system is exhausted, the carbonic acid present narcotises. Drunkenness does not set in until the person is exhausted. Those with iron constitutions may drink very heavily before they get drunk, while those who have often debauched find that less and less affects them, because they have less strength or nerve-power left for resistance. Others, again, graduate the amount, the habit slowly growing on them, until in time the nerves seem as though they would not respond—such appear to be always at their cups, but never to get drunk.

A battery will generate an amount of electricity in a given time. The quantity will depend upon the strength of the battery (number of plates), and the rapidity with which the currents are induced, while the wear and tear will bear ratio to the amount of electricity produced. Such is the case with the brain. It is a definite organ of limited capacity. It generates nerve-electricity sufficient to sustain life, to keep in action the involuntary functions, and to allow an amount for the voluntary. The whole body is in direct communication with the brain, and its vitality is sustained and supported by it. Being of limited capacity, only a certain amount of nerve-electricity can be generated in a given time, hence agents which use this up more rapidly than it is generated would in time make life untenable. This, however, is remedied by natural narcotism, induced by the carbonic acid present in the blood. This is proved thus: Dr. Parkes found that in the Ashantee war, when rum was administered, the mean ratio of the pulse in the twenty-four hours was the same as when it was not administered. It is also a well-known fact that people cannot perform the same amount of work on alcohol as on milk, or even water. Were alcohol a narcotic, the stimulus of the work ought to call the powers into play. True, after long habitual narcosis, the brain becomes impaired, and the system generally relaxed; but in the case of alcohol, a single debauch produces exhaustion. Again, carbonic acid is a narcotic; hence if an amount narcotise a strong person, will not a less amount narcotise a weaker one, and will not a still smaller amount narcotise an exhausted one? I fail to see what is to prevent such an issue. All the conditions necessary are present, the exhausted frame, the wasted nerve-power, and the carbonic acid in the blood. As to the action of alcohol, I am aware that physiologists believe that alcohol paralyses the sympathetic nerves, and that thus the cerebro-spinal exert their power uncurbed. If they are paralysed, it must be occasioned by exhaustion or physical charge. It cannot be exhaustion, as it is instantaneous, and there are no signs of action on the sympathetic, as seen under the microscope. The vessels do not at first contract, as would be the case if the sympathetic were stimulated, but they immediately dilate. It cannot be from physical charge, inasmuch as the paralysis would continue as long as, and even longer, than the presence of the alcohol. If the sympathetic were paralysed in the presence of the alcohol, the cerebro-spinal would keep up their power unchecked, and the rest of the body would be the heart, and congestion of all the viscera. In your issue of the 23rd, you note the discovery, by Continental physiologists, of vaso-dilator nerves, traceable to the cerebro-spinal, going to prove the truth of what I say, that all agents which act upon the cerebro-spinal stimulate, while those which act upon the sympathetic narcotise.—I am, Sir, yours truly,

THOMAS P. LUCAS, M.R.C.S. Eng., F.S.A., L.R.C.P. Ed.

A MAGNETINE.—Notwithstanding statements to the contrary, the pamphlet on *Magnetism*, with the name of Dr. Soutter, M.R.C.S. Eng., is still extensively circulated. Three copies lately sent to two correspondents are before us. Write to Mr. Trimmer, Secretary of the Royal College of Surgeons.

II. S.—Pope Clement VII. it is stated, sank under the baneful effluvia of a torch that was carried before him. The Italian ladies delight in the disgusting aroma of rue, which, according to their notions, dispels the *cattura aria*. Perhaps they fancy it possesses those salutary qualities to which Ovid alludes:

"Utilius summas acuentes lumina ritas,
Et quidquid veneri corpora nostra negat."

NOTICE TO ADVERTISERS.—Advertisements for insertion in the **BRITISH MEDICAL JOURNAL**, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

M.D. (Oxford)—When the celebrated Radcliffe went to Hanau to attend Lord Altemarle, he received £1,200 from the King, with 400 guineas from his patient, besides a valuable diamond ring. He died very rich, and amongst his legacies was one of £500 *per annum* for the amelioration of the diet of St. Bartholomew's Hospital.

A STUDENT.—Our advertising columns will give you the information.

PREVENTION OF QUACKS.

SIR,—I am tempted by the sensible letter of Dr. Crisp of Chelsea, with which I cordially agree, to go another step in advance, and earnestly recommend to the consideration of the profession generally the propriety of providing some official organisation whose special object would be the prosecution and punishment by law of those quacks and pretenders to medical knowledge throughout the country, whose assumption of professional titles, to which they have not the slightest right whatever, tends to lower the dignity of our profession in the eyes of an indiscriminating public. I pass by, sir, in alluding to those people, the pecuniary loss entailed by them on our profession, and also the misery often experienced by many of their unfortunate patients, though they are well worthy of consideration. Of the latter kind I could furnish examples in my own practice of the evil influence of these persons in private families—of the wife made doubtful of the faithfulness of her husband, when she herself suffers only from leucorrhœa, and of the husband also doubting the wife when he suffers from balanitis, contracted from the leucorrhœal wife, which was easily cured under proper treatment. There is a delicacy, and I believe it to be a false one, among us in taking the personal responsibility of prosecuting in these cases, and in deference to it I would suggest the consideration of my proposition. We number 30,000 in our profession in the United Kingdom; in our own Association we number between 6,000 and 7,000; surely we ought to be strong enough to look to our interests as well as those of the general public. The latter would soon recognise it. We are, and have been for a long period, working hard for the better sanitation of the country. Must we neglect the treatment of an ulcer which permeates through the vital and social relations of society. One of my professional brethren here has suggested as a plan of meeting in some measure our requirements, the appointment of consulting medical law officers, who should be specially retained, and who should receive a certain proportion of our annual payment, either from the parent or from the branch Associations, or from both. There should be a sum sufficient to make it worth the while of those gentlemen to devote themselves to the study of the subject, and they should be entitled to all costs in cases of conviction. If sufficient funds be available, there might be one such person in each large town in the United Kingdom, *i.e.*, for England, in Liverpool, Manchester, Birmingham, Leeds, Bristol, Newcastle, London, &c.; for Scotland, in Edinburgh, Glasgow, Aberdeen; for Ireland, in Dublin, Cork, Belfast; or only one for each country. These however, sir, are matters of detail. The subject has been mentioned to one of the leading members of the Council of the British Medical Association in the north of England, who promised to bring it under the notice of the Council; but so far, nothing has come from it. If the attention of the British Medical Association be drawn to this subject by my letter, my object will have been attained.—I am, etc.,

Oak Mount, Barnley, Lancashire, March 13th, 1875.

DELTA—We think that, in the absence of any agreement to the contrary, our correspondent may accept the invitation of his friends and commence practice in the town; but that he should carefully avoid and strongly resist all attempts to increase his practice by the transference of any of his late principal's patients to him.

ON THE INFLUENCE OF TEMPERATURE ON CHILDBIRTH.

SIR,—I have said that the subject is not under *tried*. If the reader have any doubt on this point, let him consult the latest authority, Dr. Leishman, who, in his most praiseworthy and painstaking work, published only a few months ago, states that his "object has been to furnish to students and practitioners a complete system of the midwifery of the present day"; and thus, judging by the highly favourable opinions everywhere expressed, he appears to have accomplished in a very satisfactory manner. In that work, which is replete with information respecting the mechanism of labour, the reader will fail to discover anything corresponding to the doctrines which you have permitted me to publish in the pages of your *JOURNAL*. In the chapter headed "Uterine Inertia and Precipitate Labour," the author begins by saying that "in no two cases of labour is the course of the process precisely similar, although the vast majority are from first to last perfectly normal". There occurs the following illustrative passage, in which the reader will be sorely puzzled to discover any expression of a rule—any normality whatever. It is a case of *lucus a non*, in fact. "Nothing is more familiar to the accoucheur than the sudden and unlooked for changes which occur in the course of an ordinary case. In one instance, the tardy and inefficient progress which has characterised it during many tedious hours, gives place, without any obvious reason, to efficient and even violent action, which brings the act to a precipitate termination; while in another, the safe and steady progress, which has led us confidently to anticipate a speedy issue of the case, is provokingly interrupted by a failure of expulsive power, and that, too, not infrequently when the second stage of labour is nearly at an end. Such occurrences as these are generally of no great importance."

One would certainly suppose that, both theoretically and practically, it would be a matter of the very highest importance to ascertain, if possible, what are the essential dynamic conditions of rapid and tedious labour. One would suppose, too, that in the volume above quoted, the influence of temperature, whether as regards the prevention or alleviation of the somewhat unsatisfactory (though, according to Dr. Leishman, "perfectly normal") state of affairs would be amply discussed. Nothing of the kind. All that is therein written having any bearing on the subject is comprised in the following sentence. "Climate and season exercise an influence which, though far from uniform, is sometimes obvious, the relaxing effect of a high temperature in those instances enfeebling the nervous and muscular tone; and it has even been stated that the result of long residence in the tropics has a permanently enervating effect, which may be manifested subsequently in temperate latitudes." Not a word is said, be it observed, respecting the all-powerful influence of warmth in promoting easy, safe, and speedy parturition; not a word, either, about the paralyzing effect of cold. Therefore the author publishes another edition of his work, let him pay a visit to the Swiss mountains, and

let him inquire into the difficulties and dangers which everywhere beset parturient women as a necessary consequence of the continually depressing influence of cold. There, in many places, he will find the inhabitants wringing their hands, and declaring in piteous accents that at such times everything always goes wrong.

The reader will not have forgotten the interesting case mentioned in a previous letter, where, at one *coup*, the whole process of parturition was happily brought to a close. Dr. Leishman has nothing to relate on this aspect of the question; he only enlarges "on the accidents which may accrue in labours which are too rapid". Indeed, the subjects of painful and precipitate labour are so inextricably blended in his book, that one would never suppose (unless otherwise informed) that a precipitate labour could, by any possibility, be easy and safe. He speaks, for example, of cases where, "although the parts are relaxed, the child may be forced through the passage with a rapidity which is truly appalling". Here, curiously enough, we witness a remnant of the old superstitious fear of a too rapid delivery, which led of necessity to the absurd and mischievous (though time-honoured) practice of "supporting the perinaeum"—a practice which, in another part of his book, Dr. Leishman very properly condemns.—I am, etc.,

Harlesden, N.W.

M.D.

PETROS.—This is the epitaph; see Wadd's *Nuga Canora*.

"Jerusalem's curse is not fulfilled in me,
For here a Stone upon a Stone you see."

L.R.C.P.—It is said that Sir Theodore Mayerne took lessons from Sir Walter Raleigh in medicine.

ARTIFICIAL LIMBS.

A HOG with an artificial leg, says the *Farmer*, must be a touching and picturesque object. The cow-catcher at Dunleith took off the hind leg of Mr. Smith's hog, and his benevolent owner made a wooden succedaneum, and strapped it to the stump. The creature shows its gratitude by accumulating fat with great rapidity, the only drawback being that when killing and curing time comes, one of the hams will have no handle.

M. B. M. ASSOCIATION.—In Edinburgh, about the latter end of July or beginning of August, full particulars will be duly announced.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—The Croydon Chronicle; The Newcastle Daily Journal; The Derby and Chesterfield Reporter; The Hampshire Telegraph; The Newton Directory; The Hereford Times; The Hackney Express; The Liverpool Mercury; The Glasgow Herald; The Birmingham Daily Post; Saunders' News Letter; The Sheffield Daily Telegraph; The Bath Argus; The Berkshire Chronicle; The Cork Constitution; The Exeter and Plymouth Gazette; The Merthyr Express; The Glasgow News; The Standard; The Folkestone Express; The Sunderland and Durham County Herald; The San Francisco News Letter and Californian Advertiser; The Western Gazette; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Mr. Lennox Browne, London; Mr. Fairlie Clarke, London; Mr. P. C. Hepworth, London; Mr. H. Sewall, London; Mr. P. Cunliffe Owen, London; Dr. A. Harkin, Belfast; Mr. J. Stannier, Folkestone; Dr. R. Bowles, Folkestone; Mr. W. E. Alston, Shorncliffe; Dr. Ogle, Derby; Dr. J. William, Penryn; Mr. A. Iveson, Hull; Dr. Pavy, London; Mr. W. Holder, Hull; Dr. A. Harvey, Aberdeen; Dr. Nicol, Llandudno; Mr. R. A. Clarke, Farnworth; Mr. W. Hammond, Nuneaton; Mr. J. Gay, London; Dr. Harvey, Llandudno; Dr. Saunders, Exeter; Mr. E. C. Baber, London; Mr. J. Ingpen, London; Mr. John Meir, Bristol; Mr. J. Ashlarton Thompson, London; Dr. Williams, London; Dr. G. F. Elliott, Hull; Our Edinburgh Correspondent; Dr. L. BOOKS, ETC., RECEIVED.

Sir Charles Bell and Sir James Young Simpson: a Biographical Study. By Samuel Garje, F.R.S.E. Birmingham: White and Pike. 1875.

AN ADDRESS

DELIVERED TO THE FELLOWS OF THE ROYAL
COLLEGE OF PHYSICIANS OF LONDON,*March 22nd, 1875.*By SIR GEORGE BURROWS, BART., M.D., F.R.S.,
Physician in Ordinary to the Queen; President of the College; etc.

GENTLEMEN,—One of my most distinguished predecessors in the office I have the honour to hold—Sir Thomas Watson—instituted the practice of giving a summary of the occurrences which had transpired during the official year; and, feeling convinced of the value of the precedent established by him, I shall venture upon this, as upon former occasions, to detain you with a few remarks.

The events of the past year have been fewer than usual, and many of them related to mere matters of routine, and are hardly worthy of being adverted to, while others are of more or less importance and of interest to the Fellows, and deserving of some further notice. Some of these, then, I shall touch upon very lightly, while upon others I shall deem it my duty to offer you more or less extended remarks, in order that they may not so immediately pass from your consideration and remembrance.

We may regard the occurrences of the past year from two points of view, according as they affect us in relation to the world around us, or as they concern our own material interests and reputation.

Our communications with the different Public Departments of the Government have been fewer than in any preceding year in which I have had the honour of holding office. We have received two communications from the Secretary of State for India respecting the treatment of leprosy with Gurjun oil; and, if the reports of the efficacy of this remedy be confirmed by subsequent investigations, an important step will have been gained in the treatment of this horrible and intractable disease. Another letter from the India Office related to the fevers and other diseases which might be expected to become epidemic after the failure of the rice crop in Bengal and during the subsequent famine, the horrors of which were so greatly mitigated and controlled by the untiring energy and perseverance of the Governor-General, Lord Northbrook, and the officials of the Government at Calcutta. All these documents were laid before the Fellows, and suitable replies were transmitted to Lord Salisbury, the Secretary of State for India.

A letter was received from the Registrar-General's office, submitting for the consideration and approval of your President a new form of certificate of the cause of death, to be filled up by all legally qualified medical practitioners who have been in attendance upon patients whose illnesses have terminated fatally. The new certificate does not materially differ from that which has long been in use. While it imposes some increased responsibility upon the medical attendant, it also allows him to make qualified statements upon points on which he has had no certain personal knowledge.

The more complete and accurate registration of the causes of death is of such essential interest and value in a densely populated and highly civilised nation like our own, that the members of the medical profession, with their usual disinterestedness, would hardly offer any captious objections to an improved form of certificate of the causes of death, although it might occasion some additional trouble.

Her Majesty's Commissioners of the International Exhibitions held in this country have presented to the College a medal, in acknowledgment of the services rendered by the Fellows towards the arrangement and enriching of certain departments of these exhibitions.

Ever since I have been connected with the College, and long before, it has been the established practice at our general meetings not to travel from that which relates to medical science and our profession generally into the wide field of politics and general legislation. Any subject which concerns the government or improvement of the education of the profession, or which affects the status or interests of certain branches of the profession, has always been considered a legitimate and proper subject for the consideration, discussion, and active interference on the part of the College, so as to procure for it proper attention by the Executive Government or the legislature.

A subject of deep and pressing social interest—one affecting the health and moral tone of a large portion of our fellow-countrymen—was introduced to the notice of the Fellows, at a general meeting, by

our late much lamented colleague Dr. Anstie. I advert to the unwholesome state of the dwellings of the labouring population from overcrowding in London and many other large towns.

I know that by many Fellows of the College it was felt that, in entering upon this subject, and presenting a memorial to the Government, inviting them to take this matter into their early consideration for legislation, we were transgressing the course of action usually pursued by the College. Admitting the correctness of this criticism, I confess to have warmly sympathised with Dr. Anstie and others upon that occasion, and to have given him my countenance and support in the resolution the College eventually adopted.

Considering how highly the College Memorial was approved by the principal organs of public opinion, and how much it has strengthened the Home Secretary in his attempted legislation to remove this great social scandal, and cause of disease and immorality, I hope the dissentient Fellows on that occasion may have become more reconciled to the somewhat unusual course then adopted.

At the close of the last year, a communication was received from the Shropshire Ethical Branch of the British Medical Association, enclosing a proposed tariff regulating the fees in that locality of surgeon-apothecaries, or general practitioners, as they are familiarly called. This document did not require any particular notice by this College, because it related exclusively to the pecuniary recompense for medical and surgical services rendered by members of a different order in the profession than our own. But this document, and others similar to it which have emanated from other sources, are indications that the profession, as a body, are becoming dissatisfied with the present arrangements for remuneration of services rendered to the public.

Several Fellows of the College have called my attention to the present unsatisfactory scale of remuneration to physicians practising in this metropolis, and have forcibly pointed out that the fee which was deemed a sufficient honorarium a century ago by no means adequately compensates the modern physician for the additional time and skill devoted to patients residing in distant parts of this vast town. In former times, it was seldom that a physician's practice extended beyond a circle of which the radius was a mile, the centre being his own home; and, if patients resided beyond that circle, the physician was almost sure to receive an extra fee. Now, it is well known that, from the enormous distance to which the town has extended in all directions, the London physician may be called to patients residing in fashionable regions, at a distance of two miles or more from his home-centre; and yet, unless some previous arrangement have been made, no extra fee is offered by patients, and can rarely be asked for without giving rise to unpleasant explanations. All who have given any attentive thought to this subject must be aware that it is not only the greater distances which the physician is compelled to traverse, but also the diminished value of money, which renders the long established conventional fee a much smaller remuneration to physicians of the present day than that always obtained by physicians of one or two generations before our own.

The greatly advanced rent of houses in suitable localities, the increased expense of carriage and horses, the rise in the wages of servants, and the augmentation in the other expenses of living, place the physician of the present day at a great pecuniary disadvantage compared with his predecessors of a past generation. While the price in money of nearly all that is required in the establishment of a metropolitan physician has steadily and greatly advanced, his services are still estimated by the same fee that was offered him when that money was worth far beyond its present value. How is this anomaly and social hardship to be remedied? I have long and frequently thought over this perplexing question, but I confess have not been able to lay down any principle which can be strictly carried out in the solution of the difficulty.

The long-established customary fee to the physician is an honorarium, and long may it continue to be so. The College have never laid down any fixed regulations as to the amount of honorarium to be expected by the consulting physician; and I would not presume to advise the Fellows to deviate from that principle. But I think I have brought under your consideration many reasons why the senior and leading members of our order should endeavour to impress upon the community the reasonable expectations of physicians to be more liberally treated in the recognition of their professional services, when distance or other circumstances cause an extra demand on their time. It has appeared to me right in the interests of our order that this delicate question should be ventilated, although I cannot presume to indicate the best course to be pursued to remedy this increasing injustice.

Just before the last autumnal vacation, a letter was received from the Society of Apothecaries, informing the College that they had obtained an Act of Parliament enabling the Society to confer with and co-

operate with the other medical authorities of the kingdom in the formation of a Conjoint Board of Examination for medical and surgical diplomas in England and Wales. Soon after the receipt of this letter, our College passed a resolution expressive of a desire that the Society should take part in the completion of the scheme already prepared, and should appoint four representatives to act with representatives of the other medical authorities in the committee called the Committee of Reference.

I feel that it must have appeared strange, and taken the Fellows by surprise, when it was announced to them that one of the medical corporations has only recently signified that it is willing and able to take part in the formation of a Conjoint Board for the examination of all who desire to be registered in England and Wales as legally qualified medical practitioners under the Medical Act of 1858. Considering how frequently this question has been brought under your consideration during the past six years, and how you have at successive periods given your sanction to the proposed scheme, as well as to the regulations for the preliminary and professional examinations under the scheme, you may reasonably require some explanation of what is implied at this advanced period of the negotiations by this last communication from the Society of Apothecaries.

I must now apologise for trespassing further upon your time and patience in bringing under your notice certain events, in order that I may vindicate your representatives in the Committee of Reference, and others who have been engaged in carrying out your various resolutions in reference to the formation of a Conjoint Examining Board, from any misrepresentations in statements, or remissness in the performance of the onerous duties assigned to them.

So long ago as October, 1869, the College received a communication from the General Medical Council, inviting the College to consider whether the time had not arrived for establishing a Conjoint Examining Board in each of the three kingdoms; whereupon, after due deliberation, this College resolved that a Committee of Fellows be appointed to confer with the Universities and Medical Corporations of England, and, if deemed advisable, with those of Scotland and Ireland, for the purpose of framing a scheme to carry into effect the suggestion of the General Medical Council.

Letters of invitation to the four English Universities, to the Royal College of Surgeons and Society of Apothecaries, to confer with our College, were then issued. As a result, several conferences were held at this College and at the College of Surgeons between deputations of the three medical corporations, and a draft scheme was prepared. To parts of this scheme the Society of Apothecaries objected, upon the ground of the proposed plan of appointing the examiners; but the draft scheme was nevertheless laid before the two Colleges, and circulated among the English Universities.

For some months in the spring and summer of 1870 all meetings to promote the conjoint examination scheme were suspended, in consequence of the introduction of a Bill into Parliament by the Lord President of the Privy Council; but, when it was made known that this Bill was withdrawn, this College again invited the College of Surgeons to a renewal of the conferences to carry out the conjoint scheme already agreed upon, or any other plan which might seem more desirable for the formation of a Conjoint Board for the examination of all candidates for licenses to practise medicine, surgery, and midwifery.

Numerous meetings of deputations from the College of Surgeons, the Society of Apothecaries, and from this College, took place in the winter of 1870-71, and in the ensuing spring. About this latter period, the delegates from the Society of Apothecaries intimated that their legal advisers had informed them that the provisions of the Act of 1815 (commonly called the Apothecaries' Act) debarred them from taking part in the scheme propounded by the two Royal Colleges, and they withdrew from all further conference.

This scheme, drawn up by the representatives of the two Royal Colleges, was laid before their respective governing bodies, and approved by them, and was then forwarded for the acceptance of the four English Universities. All the Universities intimated their assent and concurrence in the scheme.

This scheme for the formation of a Conjoint Examining Board was then transmitted to the General Medical Council in the spring of 1872, and obtained the sanction of that body, as required by the nineteenth clause of the Medical Act of 1858. Everything seemed to promise that this important national measure would now be carried into operation under suitable regulations drawn up by a committee for approval by the several co-operating medical authorities of the kingdom.

Unfortunately, an unexpected difficulty arose to interfere with the carrying out this scheme to completion. The University of London discovered that their Senate had exceeded the powers granted under charter of incorporation, in giving their unrestricted assent to all parts

of this scheme of conjoint examination. But the Senate, having been fully convinced that this plan for a conjoint examination by all the medical authorities promised to be highly beneficial to the public, although it placed some restrictions upon their own powers, sought for and obtained an Act of Parliament which enabled them loyally to act up to their previous decision, and to take their share in the formation of the Board for a conjoint examination. A committee, called the Committee of Reference, composed of delegates from the four English Universities, and the Royal Colleges of Surgeons and Physicians, now assembled and during the years 1872, 1873, and 1874, met many times (in all, I believe, thirty-five times), and drew up regulations to carry into effect the principles of the conjoint scheme.

The Committee of Reference made four successive reports upon preliminary and professional education, drawn up with the most scrupulous care, and submitted them to the co-operating medical authorities. These reports were laid before you and approved by the College, and notice was given that all candidates must, after a certain specified date, conform to such regulations.

All formidable obstacles to the formation of a Conjoint Board of Examination for England and Wales appeared to have been surmounted, and there was a fair prospect that all the protracted discussions and deliberations had been brought to a favourable issue. A fresh difficulty, however, one so utterly unexpected that no one who had been engaged in this anxious and tedious business could have anticipated it, now presented itself. The Council of the Royal College of Surgeons, which had, with our College, originated, elaborated, and promulgated for acceptance by other medical bodies this scheme for the conjoint examination, now discovered that they had agreed to proposals which their present charter would not allow them to carry into operation. Although many eminent members of the Council of the College of Surgeons had, during a period of five years, been engaged with Fellows of this College and others in preparing this measure, and had, I believe, fortified themselves by legal opinions, still this fundamental objection to their concurrence in the conjoint scheme had not been foreseen by them.

The further progress, therefore, of this great national measure in the preparation of which so much thought, labour, and time had been generously bestowed, is now suspended, and the issue is dependent upon the course which may be adopted by the Council of the Royal College of Surgeons. Following the examples of the University of London and the Society of Apothecaries, which bodies found themselves embarrassed by analogous difficulties, the Council of the College of Surgeons are seeking an enabling Act of Parliament which will give them the power to carry out, if they may think fit, the scheme which they originated and prepared in conjunction with the Universities and ourselves.

Should the Council of the College of Surgeons find themselves unable to surmount their present difficulty, there is every probability that any scheme for the formation of a Conjoint Examining Board by the voluntary co-operation of the Royal Colleges and other medical authorities will be impracticable, and that this long expected and much required modification of the existing system must be brought about by some enactment of the legislature. This latter course is, I need hardly say, most undesirable, as it will impair the prestige of the medical authorities and interfere with the independence and self-government of the profession. Although the medical profession, as a profession, may suffer from this failure of co-operation on the part of the recognised authorities, the public would still obtain by enactment of the legislature a guarantee that every legally qualified medical practitioner (come from wheresoever he may) had passed a full, sufficient, and impartial examination into his professional attainments.

I now turn from an account of the intercourse we have held with the Government and other public bodies, and invite you to a review of the state of affairs in our own College.

The statistics of the College, small in numbers as compared with the other two medical corporations, are nevertheless interesting to ourselves; and I hope my statement may appear encouraging and satisfactory to you.

We have elected during the past year fourteen new Fellows, and have lost five by death, viz., Dr. Anstie, Dr. McLennan, Dr. H. Sandwith, Dr. Edward Smith, and Dr. Beattie. Our present number of Fellows amounts to 289.

Twenty-two new members have been admitted, and nine have died, viz., Dr. F. Bird, Dr. Downing, Dr. C. J. Fox, Dr. Alexander Halley, Dr. Lankester, Sir Alexander Nisbett, Dr. J. H. Simpson, Dr. F. B. White, and Dr. W. B. Wilmot. There are now 497 members on the list. No less than 85 licentiates have been admitted; and taking into account those gentlemen who have not been able to satisfy the examiners, there have been nearly 100 candidates for admission into this

order. Seven licentiates have died during the year, and the number of licentiates actually on the list amounts to no less than 921.

This steadily increasing number of licentiates manifests how highly the College license is estimated, and how wisely the College acted some years since in extending their connection and influence through such a large section of the profession.

In addition to the classes on the College roll, which I have already enumerated, there still remain 147 names in the old orders of licentiates and extra licentiates.

I may thus, then, sum up the total number, more or less closely connected with our body, and who are affiliated to the College:—

Fellows	289
Members	497
Licentiates	921
Extra licentiates and old licentiates	147
Grand total	1,854

If, then, we have so largely increased the numbers attached to this College, and who afford us a broader basis of support, we must also remember that we have multiplied our responsibilities and obligations towards the profession. We can never again attempt to wrap ourselves up in proud isolation, and rest contented with the prestige of former days. The Fellows of the College must, by their learning, their scientific attainments, and their honourable bearing, uphold the social status of the profession, and march forward in the van of those who are labouring to extend the boundaries of medical science, and to sustain our art upon more stable foundations.

I must no longer refrain from reminding you of an occurrence connected with the internal affairs of the College during the past year, which will become part, and a gratifying part, of the history of our institution. The treasurer reported to us, at one of our general meetings, that the fabric of the College was in a rapid state of decay, from the disintegrating effects of the London atmosphere upon the stonework of the building, and that there was a necessity for immediate repairs. This serious intelligence was accompanied by the information that he had no collegiate funds available for the required repairs.

Some spirited Fellows of the College, I mean Fellows having a strong *esprit de corps*, worthy successors of those who so largely contributed out of their private means to the building of the College about half a century since, proposed that the required funds should be raised by voluntary subscriptions among the Fellows. This proposal was cheerfully adopted, and in the course of a short time a subscription was announced, amounting to a sum between eleven and twelve hundred pounds. This amount has proved more than adequate for the requisite repairs. A small committee was appointed to co-operate with the treasurer in superintending the restoration of the College, and I think all must admit that a most satisfactory result has been obtained.

The handsome and much improved external appearance of the building will, I think, be further enhanced by glazing the College windows with plate-glass; and I trust that funds may yet be forthcoming to add to the ornaments of the northern façade by placing in the niches on each side and under the portico statues of three of our most illustrious predecessors.

The College have extended their hospitality more largely this year than is their wont. Nearly ten years had elapsed since the Fellows had given a public entertainment in their College Hall, and invited to their table men distinguished in the Legislature, in the Church, in the law, in science, literature, and art. The day selected for the banquet—Midsummer day—was unfortunate, inasmuch as several other great public entertainments were given on the same day, and we were thus deprived of the presence of many distinguished persons, who would otherwise have been among the number of our guests. Her Majesty's ball at Buckingham Palace on the same evening also broke up our party earlier than we could have desired. I have reason to believe that our guests were hospitably and handsomely entertained, and that the banquet gave general satisfaction.

The evening *conversazione* given by the Fellows enabled us to receive within our College a much more numerous and diversified company, composed of members of our own profession and of many other learned and scientific societies. Our thanks are largely due to the Committee of Fellows who undertook the onerous task of arranging everything for our *soirée*, and I trust we may congratulate ourselves that our efforts to render the evening meeting both sociable and entertaining were attended with success.

I will not repeat, what I have upon former occasions expressed to you more in detail, my reasons for believing that the position of this College in relation to the surrounding world is much improved by these acts of hospitality and social intercourse.

The usual series of lectures have been delivered, and I think nobody could have listened to the discourses of the Croonian and Lumslean lecturers without feeling that most valuable and original additions to medical knowledge were made known to us, and that the reputation of the College was honourably sustained by our lecturers.

The office of Harveian orator was last year held by Dr. West, who gratified his numerous audience, composed of the Fellows and a large number of visitors, by the delivery of an oration composed in pure and classical English, and containing, as the result of extended research, most interesting details of the inner life of Harvey and his fellow-students at Padua.

I have, as your President, attended nearly all the meetings of the Trusts, in which I hold a place *ex officio*. At the meetings of the trustees of the British Museum, of the Hunterian Museum, and of the Tancred Charities, nothing has transpired worthy of being brought under your especial notice. Neither have I been called upon to exercise the privilege of the President of the Royal College of Physicians of voting for the appointment of certain professors at the Universities of Oxford and Cambridge, no vacancies having occurred during the past year.

Our treasurer, at the appointed time, submitted the books containing the College accounts to the inspection of the Fellows, and he had the satisfaction of assuring them that their financial affairs were in a more prosperous state than they have been upon some former occasions.

It is well known to you that the income of this College is small, considering the position it holds among the national institutions of the country. We may hope and expect that, if it should be called upon to perform yet more extended duties towards the profession, the performance of those duties may place increased means at the disposal of the College. This additional income would give the College the power of doing what is greatly required: first, to add largely to our library, and make it at least an useful library of reference for all classes connected with the College; and, secondly, to enable us to offer some more suitable stipends to our lecturers, and, if possible, devote some sum annually to the encouragement of original researches in medical science.

If we look to our steadily increasing numbers, and to a more satisfactory pecuniary balance, and if we regard the loyalty and *esprit de corps* prevailing among the Fellows, we may confidently trust that, as we are willing, so we shall be able to render additional services to the public and the profession, and to maintain the reputation and high character which this College has enjoyed for more than three centuries.

INTERNAL ADMINISTRATION OF TAR IN PSORIASIS.

IN the BRITISH MEDICAL JOURNAL of April 10th, 1875, I observe, under the above heading, the results of Mr. Balmanno Squire's trials of tar internally in cases of psoriasis; and the conclusion to which he has arrived is summed up in the following sentence: "I can only offer my experiment to him (Dr. Ringer), in the hope that he may think it worth while to repeat it, and report whether or not I am correct in my conclusion that tar taken internally has no effect in curing psoriasis." Having given this medicine very extensively in cases of psoriasis for a good many years, I am bound to say that the results of my experience are strangely at variance with those of Mr. Squire; indeed, I have come to regard it in the light of one of the most valuable remedies we possess in the treatment of that disease. And it is not merely in mild cases that it does good, for it has, in my hands, frequently yielded the most satisfactory results in very obstinate cases after long courses of arsenic and many other orthodox remedies had been tried in vain. Perhaps it may be that the dose and mode of administration of the tar may have something to do with the difference in the results obtained by Mr. Squire and myself; and, therefore, it may be well to state that I generally begin with two minims three times a day in a teaspoonful of treacle, and gradually increase the dose, if necessary, to half a teaspoonful, or even more. The small dose is advisable at first, as in some persons the medicine cannot be tolerated, and produces derangement of the digestive organs, fever, and a bright red rash upon the skin.

I can testify also to the virtues of this remedy in catarrh of the bronchial tubes, as pointed out by Dr. Ringer, and in chronic affections of the mucous membranes generally; and I conclude with the remark that it is very singular how such a valuable remedy, which seems in earlier days to have been highly esteemed, should, as an internal medicine, have fallen into such disrepute in our own time.

T. MCALL ANDERSON, M.D. *(Med. Med. J.)*

ABSTRACT OF THE LUMLEIAN LECTURES ON LIFE, AND ON VITAL ACTION IN HEALTH AND DISEASE.

Delivered at the Royal College of Physicians, London.

By LIONEL S. BEALE, M.B., F.R.S.,
Physician to King's College Hospital.

LECTURE II.

IN his second lecture, Dr. Beale remarked that water must be very intimately associated with the particles of living matter. These cannot be regarded as dry solids suspended and moving freely in water; for every particle is composed of smaller particles in constant motion.

The most minute living particle consists of multitudes of living centres, and we may imagine lifeless particles forming among these and coming within their sphere; but it is not possible to conceive how atoms of particles of lifeless pabulum can of themselves separate and then become rearranged and acquire living powers. There must be a transference of power from the living to the non-living; and to this capacity of making alive there seems to be no limit; there is no loss on the part of the previously living particle by the repetition of the process. This, Dr. Beale believed, is the nature of the changes in the minute particles of bioplasm in all conditions—from the bacterium to man, in health and in disease.

New centres of living matter, such as nuclei and nucleoli, appear in pre-existing living matter; a second series may appear in the first, a third in the second, and so on; and the formative power of these series and of the bioplasts resulting from their division may be different. The centres from which matter inherits vital properties must be very minute—hundreds of times more minute than the smallest particle visible with a power of 5000 diameters; and they must be larger or heavier than the ultimate atoms of the component non-metallic element. It is absurd to speak of a *living atom*, and also of *dead atoms* of carbon, oxygen, or hydrogen: every particle of living matter must be composed of several elements, perhaps of multitudes of atoms of several different elements.

But it is not merely the power of moving from centres, of progressive movement, of transforming pabulum, of forming new and peculiar chemical compounds, that is acquired, but powers far more wonderful than these, by virtue of which the living matter produces living particles, generation after generation, from which definite organisms and definite and very different tissues in each single organism result. These powers are peculiar to the living world, and there are no forces, no behaviour of non-living matter, which can be said in any way to resemble them, or to exhibit the most distant analogy to them.

The time required for the transmission of powers from living matter to that which descends from it varies greatly. One particle may require weeks or months to acquire its full powers; another only a few days. The influence of temperature, food, and external conditions, is uniform only in the case of the same species. What the organism is, depends far more on what the organism was that produced it than on its food. The pabulum of tissues of complex animals is undoubtedly peculiar, and must be prepared before it is taken up; but how is it prepared? The bioplasm of the tissues selects pabulum from the blood, which is itself formed by bioplasm. Living matter takes up pabulum of the proper kind and grows, at last becoming formed matter, which constitutes the pabulum of other bioplasts, and this occurs several times before food becomes converted into tissues. If this conversion into living matter can be explained, or can be carried out in the laboratory, let it be done.

By admitting vital power, I am able to explain results without attributing metabolic influences to cell-walls, cell contents, intercellular substance, walls of vessels, and other textures, which in reality are passive. I need not assume hypothetical actions and differentiations, or attribute to some hypothetical force, said to be akin to aggregation and crystallisation, phenomena which have not the faintest analogy with those processes; nor have I need to assume governing powers of which the mind cannot conceive, or matter-guiding forces acting in some unexplained way through all sorts of matter. Vitality acts in living centres upon matter only infinitely near the centre. This is all that is demanded by the terms of my hypothesis.

Dr. Beale then proceeded to speak of the conjectures advanced concerning the origin of life. The term "evolution", now supposed to solve the difficulty, has had at least two meanings. Some have restricted it to the living world; others have maintained that it should include not only the evolution of living from living forms, but the formation of the living out of the non-living. In support of the hypothesis of evolution in the latter of these two senses, facts are wanting, and the arguments adduced in its favour cannot have much weight. If evolution be restricted to the living world, the origin of the first living thing has still to be accounted for. With reference to this origin of the first living matter, several not improbable suggestions present themselves; in all of which, however, it is assumed that the change from the non-living to the living was sudden and abrupt, and not gradual. 1. We may conceive that one form of living matter was produced direct from the non-living, and that from this all future living was evolved. 2. We may prefer to imagine that more than one form of life originated from the non-living at or about the same time. 3. We might conceive that several different kinds of bioplasm originated in the beginning of an epoch of life, from which all life of that epoch was derived; new forms originating anew in the next epoch, the results of evolution from the first gradually dying out as those of the second epoch increased and became dominant. As life-epoch succeeded epoch, new forms of bioplasm may have appeared as old forms of life died out. These by no means exhaust the list of reasonable hypotheses concerning the origin of life.

Facts and arguments render it much more probable that the passage from the non-living to the living is sudden and abrupt, than that there is a gradual transition or scarcely perceptible gradation from one state to the other. This inference, however, is in opposition to the views of many authorities, and is opposed to the clearly expressed opinion of one of the greatest discoverers and most acute thinkers of the time, who maintains that the conversion of physical into vital modes of force is continually taking place.

Dr. Beale then proceeded to criticise the doctrine of spontaneous generation. The more accurately investigation is carried out, the more improbable does it appear that any living form should be derived from the non-living. I cannot, Dr. Beale said, but feel surprised that at this time many good reasoners should decide in favour of the *de novo* origin of bacteria. The modern advocate of abiogenesis should be skilled not only in explaining facts, but in explaining facts away. The fact that bacteria germs exist in all parts of the higher organisms, in the most internal parts as well as upon the surface of man's body, is to be accounted for by their spontaneous origin! Although millions are to be found about the mouth and upon the surface, and it can be shown that it is easy enough for them to get from the outside amongst the tissues within, we are asked to believe that those inside originated there direct from the non-living, or, as an alternative proposition, that they were derived, not from parental bacteria, but by transmutation from some of the constituents of the tissues. What is required to settle the question of abiogenesis is well devised experiment. No resuscitation of old arguments and doubtful facts will avail anything in the absence of new experiments. The only view of spontaneous generation at all tenable is, that such minute organisms as bacteria are the only ones that can be formed anew, and that these alone, at any time in the world's history, sprang direct from the non-living. That multitudes do now spring from pre-existing forms is absolutely certain, for the process can be seen. Whether some spring direct from the non-living, is the question. Those that are supposed to be formed anew are very like those that have had a progenitor; and from those supposed to have been produced anew, forms exactly like those derived from undoubtedly pre-existing forms result. It cannot be pretended that new forms of existence are produced anew. No matter how the conditions are varied, the living forms supposed to result resemble known living forms, and give rise to forms of the same kind. The question of the origin of bacteria can only be determined by experiment; for the assumed *de novo* origin is contrary to what goes on through the whole kingdom of Nature. As regards the validity and reliability of the most recent experiments for and against the doctrine, I offer no opinion. If the formation of a bacterium-germ direct from non-living matter be possible, three very remarkable series of changes, as it seems to me, will have to be brought about. Whether any means will ever be discovered of effecting these changes, is most doubtful. First, the atoms of the non-living substances must be separated from their combinations. Secondly, the atoms will have to be rearranged to constitute groups of which the organic matter is made up. Thirdly, the groups of atoms must be made to live. What facts known render it likely that air, rarefied or condensed, or pressure of any degree or of any special kind, or any degree of heat, or light, or any conceivable modification of physical or chemical conditions, would, at the same time, account for

the pulling asunder and joining together of atoms, and for the concurrence of new and peculiar powers of growth, of movement, of division, and of the formation of new substances? It is not easy to conceive, in the imagination, the several steps which result in the formation of a living bacterium even from *organic matter*.

Commenting next on the absolute distinction between the living and the non-living, Dr. Beale said that reference had been made to facts and arguments which seem to justify the conclusion, that there are certain phenomena characteristic of all living matter, and which are included under the terms *nutrition, growth, formation, multiplication*—which are not physical, and which cannot be explained by physical law. These are *purely vital actions*, and ought to be placed by themselves in a class or category distinct from that of physical phenomena. No non-living bodies present phenomena which can be fairly said to correspond to, or to be comparable with, these. The vital actions of living beings are exclusively confined to the bioplasm or living matter. When this becomes converted into any kind of formed material, or when it suddenly dies, physical and chemical changes ensue which we are able to investigate.

There is yet another consideration to be advanced in favour of the doctrine of the absolute difference between living and non-living matter. In the non-living world every change is dependent upon, or is a consequence of, anterior change; and must, in its turn, lead to consequential changes. A real cause is not conceivable in the physical world, but I do not know upon what data the same could be affirmed with respect to the living world. Consider how the simplest vital action is to be accounted for. For instance, let us inquire what was the condition of the moving matter of a common amoeba at a given spot just before the visible movement occurred. Who shall prove the nature of the antecedent to which the movement of the particles is a consequent? And who will demonstrate that the movement immediately following was a direct consequence of that which had been observed? In considering the nutrition and growth of the simplest living organism, such as the yeast-corpusele, may we not conceive physico-chemical forces to be at work there to any extent imaginable, and yet fail to gain anything approaching to an adequate explanation of the facts discerned? Let it be admitted that in nutrition electro-chemical changes play an important, perhaps an absolutely essential, part. But will these or any other physical conditions account for the formation of the matter of the "cell-wall", or the increase of the bioplasm within?

Behind all the physical and chemical actions in living beings are the changes in the bioplasm by which alone the physical actions are rendered possible and their continuance provided for. Within every centre of every one of the thousands of minute molecules of living matter constituting every particle is a more central centre in which the matter is a degree nearer the point where it began to live, and where new powers were first communicated to it. The *cause* must be, so to say, very central; and in living matter the direction of the action of the forces is from, and not towards, centres. That forces in the environment react upon the force or power acting from the centre may be fully admitted; but that these are the *cause* of central activity, is clearly untenable. The central action is absolutely essential, and the difference between the matter in the centre, and the matter in the environment, is absolute.

The phenomena which I have described as characteristic of every kind of living matter in nature, and which are known only in connection with living matter, I must ask you to regard as *purely vital actions* due to the operation of a force or power capable of controlling matter and its forces, but neither originating in them, nor formed by or from them, nor capable of being converted into them—a power which we cannot isolate or physically examine, but the effects of the action of which we may study.

The next point adverted to was the construction of the body by bioplasm. After some preliminary remarks, in which the lecturer further criticised the doctrine of evolution, he proceeded to consider in outline the changes which occur when bioplasm, manifesting its wonderful developmental powers, at last gives rise to the formation of tissue.

The earliest state of matter, in every kind of development, is that of bioplasm, derived from pre-existing bioplasm. The masses of living matter absorb nutriment, and the whole increases in bulk. So far, the only indication of formed material is afforded by the presence of a little soft transparent mucus-like matter, without any indications of any definite structure, accumulated around each mass of bioplasm. During the development of tissue, bioplasm-masses, embedded in their soft matter, continue to divide and subdivide. As development advances, there may be discerned amongst the bioplasts, here and there, one which undergoes more active change than the rest. This, in fact, becomes a new centre, from which growth proceeds, while the neighbouring bioplasts remain passive for a time, and some gradually waste.

Soon, by division and subdivision, a collection, composed of a new series of bioplasts, results. Many such collections are formed, being separated from one another by the altered bioplasm particles of the previous generation, and their imperfectly developed formed material. Thus result the first indications of the structures and organs in the embryo at a very early period of development. The process is repeated many times, probably ere the first traces of actual structure with capacity to act are to be detected. Nay, the tissue which is at last formed, and which acts, exhibits structure, but this first tissue is only temporary, and differs in its characters from the permanent texture which is at length formed. Thus, the first muscular tissue which is produced in the mammalian embryo only lasts for a short time, and it is entirely replaced by a form of contractile tissue, which differs materially from it in structural arrangement and in mode of growth. The formation of cartilage, bone, nerve-tissue, glandular and other organs, illustrates the same fact.

But formed material results from changes in bioplasm. The production of formed material may be studied in the early development of any of the tissues, and, in many of them, at any period of life. In all cases, the newest formed material is that which is nearest to the living matter. This formed material is pushed out, and a more recent formation occupies the space between it and the bioplasm. Gradually the formed material loses water, becomes firmer, and slowly undergoes other alterations, until it assumes its characteristic form and begins to fulfil its proper function. In some cases the bioplasm actually moves onwards, leaving the formed material, which it has produced, behind it. This phenomenon occurs in certain forms of yellow elastic tissue and muscle.

However long a period may elapse before the formed matter assumes its characteristic peculiarities and becomes functionally active, its characters, its properties, and its chemical composition mainly depend upon the changes which occurred just at the moment it ceased to be bioplasm, the time when they assumed the condition of formed material. If we desire to discover the true cause of the formation of tissue, we must search for it in the bioplasm ere formation occurs. According to my idea, there is something operating in each kind of bioplasm which in fact determines the kind, by virtue of which the living matter must grow and must produce formed material of a certain character, if only it be supplied with pabulum, and be placed under certain conditions. This something is, I believe, a power or force which the bioplasm has derived from pre-existing bioplasm. Condition may indeed modify the action of this power within certain limits, or may prevent its action altogether; but that the action results from the power, and ought not to be attributed to the conditions, is obvious from the fact that one form of bioplasm exposed to the conditions favourable to the developmental phenomena belonging to another kind, will not be so influenced as to exhibit these.

The characters of previous generations are indelibly stamped upon every individual belonging to each generation, and these inherited characters can be transmitted by the bioplasm only. Those peculiarities of external form, and of external and internal structure and action, in which one species differs from all others, must also be attributed to the vital phenomena of the bioplasm. In like manner the power of origination, and handing down of newly acquired properties and characters, is limited to bioplasm. Bioplasm is the agent concerned in the transmission of all hereditary structural peculiarities. There is nothing in the non-living world that presents any analogy with this marvellous power of inheriting from predecessors definite characters, and transmitting them to those that succeed. All will accept Mr. Darwin's conclusion, that, whenever variation occurs, the cause of variation must be attributed to something in the "nature or constitution of the organism"—or, as I venture to think, we may say with still greater accuracy, to something in the nature or constitution of the bioplasm from which the organism is developed. This cause of variation must, as it seems to me, be very closely related to the cause of the formation of tissue by bioplasm, and is in its nature *vital*—not *physical*.

The early changes in development require a considerable time for their completion, but the laws by which varying rates of growth in different living forms are governed or determined have not been discovered. Although wonderfully little pabulum is taken up, and but a small quantity of matter undergoes change, phenomena of paramount importance proceed, and time is very necessary for the completion of these early changes in all organisms, and especially, of course, in those that are complex. In vegetable organisms, the time that must elapse between the completion of the formation of the seed and its germination varies very much, as also the periods of time during which the seeds of different plants will retain their vitality, and this must depend upon inherent properties of the bioplasm. So also, with respect to the periodical rests from growth, the greatest individual differences are

noticed. Inherent vital peculiarities also manifest themselves in cases in which a moderate rise of temperature is far more damaging to the vital phenomena of the normal bioplasm than a corresponding fall. If the average temperature be a little above or below that which is adapted for the growth and development of certain creatures, the organism soon begins to suffer; and many tissues, although they may be formed, never attain the most perfect construction possible, or their highest functional activity, and probably they begin to deteriorate long before those of corresponding organisms which are developed under the particular conditions suited to their special vital phenomena. Is there not something very remarkable in the fact of the existence of powers or properties in the several kinds of bioplasm, by virtue of which, each seems to grow and flourish only within its own particular range of temperature? We cannot even lay it down as a law that a low temperature is necessarily destructive of vital action, for there are organisms which flourish at or below the freezing point of water. In short, the various forms of bioplasm have their individual peculiarities and characteristics, which they inherit, and may transmit, and which are not to be accounted for by physics, and which seem in truth to belong to their constitution. Conditions which are life to some forms of bioplasm are death to others.

Some are content to be assured that peculiarities from time to time originate, and that their fortunate possessors gain thereby great advantage, so that they are enabled to overcome their less fortunate brethren, and even to utterly exterminate them. Being the fittest to live, the few soon predominate. Bioplasm, with the newly acquired properties, transmits the peculiarities to that which descends, until bioplasm, capable of producing an organism still more fit, somehow results. The organisms derived from this then prevail, and enjoy the advantage of living and continuing the race. So the experiment is supposed to proceed.

ON THE ACTIONS OF Picrotoxine, AND THE ANTAGONISM BETWEEN Picrotoxine AND CHLORAL HYDRATE.

By J. CRICHTON BROWNE, M.D., F.R.S.E.,

Medical Director of the West Riding Asylum.

(Concluded from page 507.)

To give greater completeness to the inquiry into the antagonism between picrotoxine and chloral-hydrate, it was judged advisable to test its existence in another class of animals besides rabbits and guinea-pigs. A few cats were, therefore, obtained, and to two of them picrotoxine alone was administered, in order to ascertain its unmodified effects.

Experiment LXXXIX.—Cat, weighing 4 lbs. 13 oz. The cardiac pulsations were 120, and its respirations 36 per minute. Under the skin of its back, one-sixteenth of a grain of picrotoxine was injected, at 12.10 P.M. An almost immediate effect was observed. At 12.15, the respirations were 48 per minute, and much fuller and deeper; there were incessant licking of the lips and slight shakings of the head. At 12.17, saliva was dropping from the mouth, and there were dullness and stupidity. At 12.19, the flow of saliva was very large, and the eyes were being constantly opened and closed. At 12.21, the blinking of the eyes continued, and there were restless movements of the ears, while the animal was dull, and not readily roused. At 12.23, the saliva, which at first dropped from the mouth, had become so viscid that it hung in long wreaths, reaching from the lips to the table on which the animal sat, blinking both eyes vigorously. At 12.25, the bowels acted freely; the respirations were at the rate of 180 per minute. At 12.27, there were slight twitchings of the eyelids, ears, and cheeks, most pronounced on the left side. At 12.29, these twitchings continued, and were more severe, while enormous quantities of viscid saliva flowed from the mouth. At 12.31, there were occasional violent startings of the head; the animal was more easily alarmed, and any loud noise caused the ears to be drawn back and flattened. The respirations remained at 180 per minute. At 12.33, the slight twitchings of the eyelids, nose, and ears were continuous, while, every thirty or forty seconds, there were more general and severe startings. Saliva still flowed in excessive quantities, and the pupils were dilated. At 12.35, the severe startings recurred every thirty seconds, and were seen to consist in a sudden movement, forwards and downwards, of the head, with stretchings of the neck, and in raising of the shoulders. The movement altogether recalled that which is made by a cat when voraciously chewing and swallowing a rather large morsel. At the same time that the head was pushed forwards, the ears were drawn backwards and downwards. Intermediate between the more violent movements, slight

twitching, particularly in the eyelids, causing blinking, continued. The animal remained in a sitting position, and was drowsy; its pupils were widely dilated, and saliva still dribbled copiously from its mouth. At 12.40, no change had taken place; but, at 12.50, there were twitchings of the left fore-paw which was first stretched out, then raised in the air, and subjected to clonic spasms; respirations 138. At 1.5, the twitchings were less incessant and severe, and, at 1.15, they ceased altogether. At 1.20, the flow of saliva was much diminished, and the animal was more lively and able to move about, the respirations being then 60 per minute. At 2.15, the animal was in all respects recovered.

Experiment XC.—A large cat, weighing 6 lbs., had one-fourth of a grain of picrotoxine injected at 2.20 P.M. An instantaneous effect was noticed; the animal was restless, and in two minutes saliva began to drop from the mouth. At 2.24, there was loud mewing, and the head began to shake. At 2.25, there was emprostotonos; the head was drawn down, until the forehead was pushed against the table, and the back arched upwards, while there were violent general startings. At 2.26, after several attacks of emprostotonos, the animal tumbled on its side, when its head was suddenly drawn backwards, and its pupils were dilated to their widest possible extent. The fore limbs were stretched out, and the toes and claws were expanded, but the hind limbs were drawn up and remained in a flexed position. There was violent working of the mouth which was surrounded with foam, as well as twitching of the nose, eyelids, and ears. There were also severe spasms of the fore limbs. Several times the animal endeavoured to get on to its feet, but was unable to do so. At 3.32, the head was drawn down between the legs, and the back was arched upwards, the fore limbs were semiflexed, and the toes and claws folded in; the ears, eyelids and brows were in constant movement, the tongue was being constantly protruded and drawn back into the mouth, and it, as well as the lips and mucous membrane of the mouth, had a livid colour. The pupils were contracted to mere slits, and the animal was apparently unconscious. At 3.36, the clonic spasms were interrupted for a little, when the pupils at once dilated, but, at 3.38, they recurred, and then the pupils became once more contracted. From this time, however, the clonic spasms were much less severe. At 3.42, there were constant slight twitchings of the upper lip, eyelids, ears, head, and paws, with low moaning sounds. At 3.47, there were momentary intervals between the discharges, and in these intervals the pupils dilated slightly, always contracting again with each fresh discharge. At 2.50, the animal died, when the pupils at once dilated widely.

The action of picrotoxine upon the cat, as exhibited in these experiments, did not seem to be very dissimilar to its action upon rabbits and guinea-pigs. Increase of the salivary secretion and of the peristalsis of the bowels, hurried respiration, tonic and clonic spasms, with coma, were all included in its effects. One of its effects, however, that upon the pupil, was more distinctly manifested than in the other animals named. It first enlarged and then diminished the size of the visual aperture, and it should be noted that the dilatation was synchronous with opisthotonos, the contraction with clonic spasms. I have remarked that in cats, in which the movements of the iris are very easily observed, toxic agents invariably induce contraction of the pupil contemporaneously with clonic spasms and dilatation of the pupils with tonic spasms. The phenomena of absinthia, strychnia, and opium-poisoning in cats, will afford verification of this statement. Sometimes, during clonic spasm, the pupils may be seen contracting with each discharge, and dilating during each interval; so that, if the discharges succeed each other very rapidly, the irides have an oscillatory motion. I think I should be justified in saying, that the dilator muscle of the iris ought to be grouped with the extensor muscles, which are generally predominant in action in acute tonic spasms, and its sphincter with the flexor muscles, which predominate during clonic spasms.

The similarity which was demonstrated to exist between the effects of picrotoxine as seen in the cat and those observed in the rabbit and guinea-pig, gave good grounds for anticipating that chloral-hydrate would control those effects as conspicuously in the former as it did in the latter animals. No misgivings of the result were, therefore, entertained when the following experiment was undertaken.

Experiment XCI.—Cat, weighing 5½ lbs. At 2.54 P.M., one-fourth of a grain of picrotoxine and twenty grains of chloral-hydrate were simultaneously injected. At 3.7, the animal was restless and uttering low cries. At 3.13, it was drowsy, and mewing occasionally. At 3.15, there was a severe fit, in which the fore legs were spread out and the head was shaken, the ears being folded backwards, while there were also violent general startings. At 3.20, the cat died suddenly without any further convulsions.

The termination of this experiment was unexpected and somewhat

perplexing. It suggested a doubt whether chloral-hydrate was at all antagonistic to picrotoxine in the cat, for, when they were given together, the cat died just as soon as when the same dose of picrotoxine was given alone. On reflexion, however, the theory was adopted that chloral-hydrate exerts its effects upon the cat more slowly than it does upon the rabbit, while picrotoxine acts upon the cat more rapidly than upon the rabbit, and that accordingly the fatal action of picrotoxine might have expended itself before the saving action of chloral-hydrate came into play. If that were so, it was probable that the same was the case with reference to strychnia, and so the next experiment was instituted to settle that important point.

Experiment XCII.—A large cat, weighing 5 lbs. 6 oz., had one-fiftieth of a grain of strychnia and twenty grains of chloral-hydrate injected simultaneously. In three minutes, its ears were strongly drawn backwards, and it was startled by the slightest noise or movement. In four minutes, there was sudden opisthotonos, the head was drawn back, the pupils dilated, the limbs extended. Tonic spasms lasted for five minutes, when death occurred, just nine minutes subsequently to the injection.

Here was evidence that chloral-hydrate is practically as inefficacious in counteracting strychnia as it is in counteracting picrotoxine in the cat. And here also was confirmation of the view that its inefficacy in counteracting picrotoxine ought to be attributed to the comparative tardiness with which it asserts its influence over the nervous centres in that animal. To obtain conclusive proof or disproof of that hypothesis, chloral-hydrate was next administered by itself to a cat, and its effects were narrowly watched.

Experiment XCIII.—A cat, weighing 6 lbs., had twenty-five grains of chloral-hydrate administered by hypodermic injection. No change was noticed in it for twenty minutes after the injection, when it became restless, and at the same time rather unsteady in its movements, staggering a little when it walked about. In thirty minutes, after violent retching and vomiting, it was decidedly restless and unsteady, swaying about when walking, chiefly, as far as could be judged, owing to impairment of power in the hind quarters. The cardiac impulses were 120 per minute, and feeble in character, and the respirations were 52 per minute. The pupils were of an average size. In fifty minutes, it was still awake and very restless, lying down for a few seconds, and then staggering about the room purposelessly. When attempting to walk, it would cross its fore-feet, reel from side to side, stop and endeavour to steady itself, then stagger onwards, tumble over on its side, and regain its feet after much floundering. Its hind legs were very deficient in power, and frequently gave way under it. Its breathing was laboured, and its heart's action very feeble and irregular. It was somewhat drowsy, and whenever it sat down, manifested a tendency to drop off to sleep. In one hour, it had brief snatches of sleep, broken by frequent movements and low cries. Its heart's action was imperceptible, and its respirations were 69 per minute and irregular. In an hour and ten minutes, it was again awake, and staggering about more unsteadily than ever, and dragging its hind-legs after it. The hind-legs, however, as well as the tail, retained undiminished sensibility. In an hour and a half, it was lying on its side deeply asleep, sometimes, however, starting, and subject to attacks of general shivering. The heart's action was a mere flutter, and the respirations were 42 per minute, and frequently interrupted. In two hours, it was lying on its side sleeping quietly. When its tail was pinched, it would emit thirty or forty low monotonous cries in succession. In three hours, it was still more deeply asleep. It lay with its tongue protruding from its mouth, and did not move or cry out when its ears or whiskers were touched, or when its tail was pinched. There were occasional shiverings; its muscles were flaccid; its respirations 40 per minute. In this state it continued for thirty-six hours after the injection, when it died. During the whole of these thirty-six hours its bowels did not act, nor was its bladder evacuated.

Experiment XCIV.—A cat, weighing 7 lbs., had forty grains of chloral-hydrate administered by hypodermic injection. It was restless for one hour, during which time it vomited and had several attacks of retching, and at the end of which it fell into a deep sleep. Its respirations became gradually slower; it uttered from time to time low growls resembling those of a tiger. In three hours, however, it was deeply asleep, and could not be roused. For fifty-six hours it remained in this deep sleep, and at the end of that time it died, having been several times fed by a tube passed down the oesophagus. Throughout the whole of that protracted sleep, or trance, it passed no urine, nor was there any evacuation from its bowels. On examination of the body, it was found that all the vessels of the skin and all the subcutaneous vessels were engorged with blood; but that the intracranial sinuses were empty, while the brain itself was very anæmic. There was, however, a patch of hyperæmia over the cervical portion of the spinal cord. The

left side of the heart contained dark fluid blood, and the right side contained, in addition to this, some membranous clots. The lungs were highly congested, and cedematous, and the bladder was distended with urine.

These experiments confirmed the opinion which had been formed that chloral is much slower in its action upon cats than upon rabbits, and they revealed some other important facts in connection with its action upon the latter animal. They showed, for instance, that in cats, as in dogs, chloral induces a stage of excitement or intoxication with impairment of muscular co-ordination prior to the stage of sopor, that it induces sleep, passing into coma, in which all the bodily functions are retarded or are arrested, and that its effects may be protracted to an extraordinary extent. One other important fact they also disclosed, and that was that the fatal dose of chloral hydrate in cats is small when compared with that in rabbits. These and some other experiments not here recorded with reference to the fatal dose of chloral-hydrate have led me to deduce a general law, that the energy of the action of that drug is in exact proportion to the development of the cerebral hemispheres. The minimum fatal dose may, I think, be taken as a measure of the energy of action. Now, when the cerebral hemispheres are small and simple in structure and arrangement, a very large dose of chloral-hydrate in proportion to body-weight is required to cause death. But, when they are large, complex, and highly differentiated, a comparatively small dose will ensure that result. In the rabbit, the brain of which is almost smooth, the minimum fatal dose is not less than twelve grains to the pound of body-weight. In the cat, the brain of which is considerably convoluted, the minimum fatal dose is five grains to the pound of body-weight; and in the human subject, in whom the brain is supremely rich in gyri and grey matter, the minimum fatal dose is a little over one grain per pound of body-weight. In microcephalic idiots, again, I have noticed that a proportionately larger dose of chloral-hydrate is requisite to induce its physiological effects than in persons with fully developed brains. But, while the energy of chloral-hydrate appears to be in relation to cerebral development, there are other conditions, which I am not prepared to specify, which determine the rapidity or slowness with which its effects are established in different animals, and also the duration of these effects. This, however, seems to be the general rule, that, where its effects are slowly established, they are long sustained, and that, where they are rapidly established, they are more transitory.

If the supposition were correct, that the failure of chloral-hydrate to antagonise picrotoxine and strychnia in the cat in the experiments above described was due to the comparative slowness of its action, it followed that, when time was given for the establishment of its action before the administration of the picrotoxine or strychnia, the antagonism would become sufficiently apparent. To test this point, the next experiments were performed.

Experiment XCV.—Cat weighing 5 lbs. 8 oz. At 3.32, twenty grains of chloral-hydrate were injected; and ten minutes later, at 3.42, when the animal was still awake and lively, one-tenth of a grain of picrotoxine was injected. At 3.50, there were retching, vomiting, rapid and irregular breathing. At 3.56, there was emprosthotonos. The head was drawn down between the legs, while the ears and eyelids were twitched. At 3.59, there was a sharp attack of clonic spasms; and at 4 P.M. the animal died suddenly and unexpectedly.

Experiment XCVI.—Cat weighing 5 lbs. 12 oz. At 1.37 P.M., twenty grains of chloral-hydrate were injected; and an hour afterwards, at 4.17, when the animal lay upon its side in a sleep from which it could readily be roused, one-tenth of a grain of picrotoxine was injected. At 4.25, the breathing was hurried and irregular, and the heart's action intermittent. At 4.40, there was violent retching. At 4.50, the heart's action was imperceptible; and at 5.10 death took place, no spasm of any kind having occurred.

A new light was thrown upon the subject by these experiments, making it evident that, while picrotoxine and chloral are antagonistic to each other in cats in certain directions, in others again they are in fatal harmony. It became evident that chloral does oppose and nullify the action of picrotoxine upon the motor centres, but that it combines with picrotoxine to arrest the action of the heart, and so hastens death. In Experiment XCVI, the cat died without having suffered from any convulsive action; and in Experiment XCV, it died after an amount of convulsive action by no means adequate to account for death by exhaustion of the nerve-centres. On reverting again to Experiment XCIII, it was remarked that in it the cat died actually more speedily than it would have done had the picrotoxine been given to it alone, and after only one convulsive seizure; whereas the same dose of picrotoxine given alone would in the same time have induced numerous seizures. In all these experiments, death was due, not to the immediate effects of the picrotoxine, nor to the immediate effects of the

chloral, but to the combined action of both. It depended, not upon exhaustion following violent discharges of nerve-force, not upon profound coma, but upon a sudden failure in cardiac power.

The effects of chloral upon the cat are exceedingly like those of chloroform, only more protracted; and among them, therefore, is a weakening or paralyzing effect upon the heart through its special vaso-motor nerves and ganglia. Then, on the other hand, among the effects of picrotoxine upon the cat, is a retarding influence on the heart and prolongation of its diastole through increased inhibitory power exerted by the vagi. If, then, the paralyzing influence of chloral is exerted on the heart contemporaneously with the inhibitory influence of picrotoxine, we can readily understand why syncope and death should ensue, and why practically no antagonism exists between them, although chloral-hydrate mitigates the cerebral irritability brought on by picrotoxine, and although picrotoxine restricts the depth of the hypnotism brought on by chloral.

The danger of the conjoined action of chloral-hydrate and picrotoxine on the heart is greatest during the earlier stages of the action of the former, when some degree of excitement is present; and so trial was made of the effect of picrotoxine when given to a cat that had passed altogether through the period of chloral excitement into deep chloral sleep.

Experiment xcvi.—A cat weighing 5 lbs. 2 oz. had twenty grains of chloral-hydrate hypodermically injected at 11.45 A.M. At 1.45, it was deeply asleep, after much restlessness alternating with drowsiness; and then one-sixteenth of a grain of picrotoxine was injected at 1.50. Its sleep was disturbed; there were movements of the paws and tail, and general quiverings. At 2 P.M., however, its sleep was again calm and profound. Throughout the afternoon, it had alternate periods of sleep and wakefulness. During the latter, it got up and staggered about as if drunk, its pupils being widely dilated. During the former, it lay upon its side, its head being bent down, and its back arched in a distinctly emprosthotonic attitude. Whenever it was moved out of this position, it forthwith, without waking, resumed it. At 9 P.M., its sleep was continuous, and there were no spontaneous movements. It remained in a deep uninterrupted sleep for two days and three nights, when it began to recover itself. In a few hours more, it was quite well. Throughout its long sleep, its bowels did not act, nor did it void urine. When its tail was pinched, it did not flinch. Milk was frequently administered to it, and it was kept warm.

The description of further investigations which have been undertaken, but which are not yet complete, with the purpose of ascertaining the effects of the combined administration of picrotoxine, chloral, and atropine, picrotoxine, chloral, and digitalis, and picrotoxine, chloral, and alcohol, must be reserved for a future contribution to these pages, in which it is hoped that the effects may also be recorded of the continuous administration for long periods of small non-fatal doses of picrotoxine to animals. If, as has been repeatedly alleged, *cocculus Indicus* is extensively employed by dishonest brewers to impart bitterness and inebriating qualities to the pernicious liquids which they sell as beer, it is certainly eminently desirable that we should accurately ascertain the effects upon health of such a dietetic counterfeiter; and this can only be satisfactorily done by watching the effects upon animals of minute and frequently repeated doses of the suspected adulteration. In the meantime, however, we are not without indications of the evils wrought by such deleterious additions to a popular beverage. When giving evidence before the Select Committee of the House of Commons on Habitual Drunkards in 1872, I suggested that perhaps the greater prevalence of epilepsy in England than in Scotland was to be ascribed, partly at least, to the preponderance of beer-drinking and to the adulteration of beer by *cocculus Indicus* in the former country. Further observations have only tended to strengthen my belief in the theory which I then broached. Large quantities of Levant nuts are imported annually into this country, and the difficulty is to find any destination but the brewer's vat for these importations. But the action of these Levant nuts upon those who partake of them or of their active principle is to set up an unstable condition of the nervous centres, which eventuates in paroxysmal discharges analogous to, if not identical with, epileptic fits. If, then, we find that beer is adulterated with *cocculus Indicus*, that *cocculus Indicus* is adequate to the production of epileptic conditions, and that beer-drinking and epilepsy are generally in proportion to each other in their prevalence in the population, there are good grounds for holding that the adulteration of beer is responsible for much of the epilepsy by which this country is now so grievously afflicted.

And there are still other inquiries in relation to picrotoxine which remain to be made. Its therapeutic properties ought to receive attention. Many years ago, Sir Robert Christison pointed out that the actions of

this agent in medicinal doses were deserving of investigation; but the hint which he then gave has not yet been acted on. Now, however, we know that picrotoxine is a powerful stimulant to certain nervous centres; and we have therefore reason to hope that it will prove useful in some diseased conditions in which symptoms of diminution of function in these nervous centres are apparent.

The following general conclusions seem to be fairly established by the investigations which have been described in the foregoing paper.

1. Chloral-hydrate is physiologically antagonistic to picrotoxine in rabbits and guinea-pigs, and will, when administered in a suitable and proportionate dose, save life after a fatal dose of picrotoxine.

2. The antagonism of chloral-hydrate to picrotoxine in rabbits and guinea-pigs may be exerted so as to save life, even when it is not administered until fifteen or twenty minutes after the fatal dose of picrotoxine.

3. The antagonism of chloral-hydrate to picrotoxine is subject to two limitations: *a.* That the dose of picrotoxine may be so large as to kill before the chloral-hydrate has time to operate; *b.* That the dose of picrotoxine may be so large that nothing short of a poisonous dose of chloral-hydrate would avail to counteract it.

4. Picrotoxine is to a very limited extent antagonistic to chloral-hydrate in rabbits and guinea-pigs, by mitigating the hypnotic effects of the latter upon the brain and higher nervous centres, which it stimulates to activity.

5. The minimum fatal dose of chloral-hydrate in the rabbit is twelve grains to each pound of body-weight.

6. Practically no antagonism exists between picrotoxine and chloral-hydrate in the cat, nor between strychnia and chloral-hydrate.

7. Picrotoxine and chloral-hydrate, when administered simultaneously to the cat, cause death by stopping the action of the heart, and not by any destructive or exhausting action upon the supreme nervous centres.

8. Chloral-hydrate causes in the cat excitement and restlessness, with motor defects prior to the state of sopor, and its effects upon that animal are protracted to an extraordinary extent.

9. The energy of the action of chloral-hydrate, as measured by its minimum fatal dose, is in proportion to the development of the cerebral hemispheres.

In closing this paper, I have to express my gratitude to my colleague Dr. Lawson for much valuable assistance, in making some of the observations upon which it is founded.

ON PUERPERAL FEVER.

By EDWARD JOHN TILT, M.D.

ONE good result of discussions like that on puerperal fever, now proceeding at the Obstetrical Society of London, is, that it brings to light valuable cases, like two that were published last week in this JOURNAL by Mr. Stewart of Barnsley. He truly remarked "that they were exceedingly interesting from their tendency to throw light upon the nature and production of puerperal septicæmia, as they show that the application of decomposing lochia alone to a recent scratch or wound has been sufficient of itself to produce gangrene of the part and death of the patient in the one case, and a very severe attack of phlegmonous erysipelas in the other, although no puerperal condition existed in either of the inoculated subjects. I think we may, therefore, draw the conclusion, that the passage of decomposing lochia over any abraded surface in the vaginal passage is sufficient to produce puerperal septicæmia without the importation of any other specific poison. In this manner, we may account for the disease attacking much more frequently primiparous cases, as the vagina and perineum are much more likely to be slightly lacerated in those than in multiparæ."

All this is no doubt true, but it has been already pointed out; and the interest of the cases lies in the fact that they show the precise channel through which a woman frequently pours into her blood the poison secreted in her womb. The lymphatics surrounding the recent scratch of one woman, and the cut thumb of the other, took up the poison, passed it on to the lymphatics of the forearm, and they into the blood. What became of the inflamed lymphatics in one case is not said, but in the other they inflamed the surrounding cellular tissue. In exactly the same way, the lymphatics in and around a rent of the circular fibres of the internal os uteri, or of the cervix, on the "fourchette", often take up the poison that comes down from the puerperal womb, and transmit the poison to the pelvic lymphatics, that pour it into the blood. The contact of the poison with these lymphatics influences them in various degrees, and sometimes acutely inflames their surrounding cellular tissue. This is called pelvic cellulitis; but, when

the same process occurs under the skin, as in one of the two cases, it goes by the name of phlegmonous lymphangitis. I said the passage of the puerperal ichor through the larger lymphatics caused various degrees of inflammation; and the error of Cruveilhier and the pathologists of his time was to suppose that puerperal fever could not be attributed to the lymphatics unless they contained pus. In my paper on lymphangitis in pelvic pathology, I have cited cases of puerperal fever in which the enlarged lymphatics were found to contain not pus, but a fetid brown fluid, similar to that found in the womb, containing a bit of putrid placenta. I have, moreover, shown that when filtered putrid lochial fluid is injected into the womb of recently delivered animals, this gives rise in all to the same typhoid symptoms; but, on opening the animals, it is found that sometimes the lymphatics contain pus, and at others a fetid sanious fluid like that found in the womb.

SPINA BIFIDA.

By E. NOBLE SMITH, L.R.C.P.Lond.

MR. BURTON'S communication upon this subject induces me to again express a doubt that a case of spina bifida, in which the cord communicates with the sac (*i.e.*, adheres extensively to the back of the sac), can be cured by an operation which causes the sac to contract and shrivel up. The success attending Dr. Morton's treatment seems, in a very great measure, due to the modifications which he has introduced. This fact I fully recognise, but I trust I may be allowed to express a doubt as to the spinal cord being connected with the sac in the manner shown in the diagrams given below, or in the preparation, a drawing of which accompanies Sir Astley Cooper's cases reported in the *Medico-Chirurgical Transactions*.

In answer to a former letter of mine, Dr. Morton observes (*BRITISH MEDICAL JOURNAL*, November 21st, 1874) that, as all his cases have been successful, he had not had an opportunity of making a *post mortem* examination of an injected case. Five consecutive cases treated according to Dr. Morton's plan recovered. A sixth is now reported, which has failed.

I now venture to analyse these five successful cases.

CASE I (*BRITISH MEDICAL JOURNAL*, April 6th, 1872). *Spina bifida in a child two months old.*—"Its covering was thin, so that it was quite translucent; and at the child's birth it was about half its present size; moderate pressure upon it did not cause much inconvenience or suffering; and the child had never had convulsions, and seemed in all other respects quite healthy." It was cured by Dr. Morton's injection. In this case, there is no evidence of the cord communicating.

CASE II (*BRITISH MEDICAL JOURNAL*, June 15th, 1872). *Spina bifida in a child fourteen days old.*—Dr. Morton's assistant reports, that "the tumour was as large as a middle-sized orange, and cylindrical in shape. In some parts it was reddish, and at others bluish in tint. It was semi-transparent, and somewhat wrinkled on the surface. It became tense when the child cried. On looking through it, several striæ were seen passing over its internal surface." There is no proof that these striæ were nervous, and, as the child does not seem to have suffered at all from convulsions or paralysis, I think it is highly probable that they were only inflammatory adhesions. This opinion is strengthened by the fact that the tumour "at birth was small, but had increased in size", and that "some time ago it showed signs of ulceration, but these healed up, leaving thickened cicatrices of different colours". It was cured by Dr. Morton's injection.

CASE III (*BRITISH MEDICAL JOURNAL*, April 26th, 1873).—Dr. Watt reports a case in which the spina bifida was a sessile semi-transparent flesh-coloured fluctuating tumour, as large as an ordinary sized hen's egg. It was extremely sensitive, and, "when viewed by transmitted light, cords were seen passing near the surface". There is much more evidence in this case in favour of the cord communicating to some extent with the sac, for the child moaned almost constantly. "Its legs dangled, and no voluntary attempt was made to move them", and "the sphincters seemed very weak". This tumour was injected with Dr. Morton's fluid, and the tumour contracted into "a cake of firm condensed tissue", but "the legs never moved together, but, when the soles were tickled, one or other leg was drawn up a short distance". There is no absolute proof, however, that the cord communicated with the sac, nor does there seem to have been a complete cure.

CASE IV (*BRITISH MEDICAL JOURNAL*, January 31st, 1874). Reported by Dr. Watt.—The child made an excellent recovery after injection with Dr. Morton's fluid. The tumour "was very sensitive to the touch, became tense when the child cried, and palpation discovered a perfectly fluid condition", which is equivalent to stating that the cord did not communicate with the sac.

CASE V (*BRITISH MEDICAL JOURNAL*, October 24th, 1874). Re-

ported by Dr. Morton. In this case, the tumour was situated in the cervical region, and no evidence is given of the spinal cord being involved in the sac.

The accompanying cuts represent two preparations in the Museum of the College of Surgeons, of which Mr. Flower kindly allowed me to

make drawings, and I cannot understand how such cases could be cured by making the tumour contract and shrivel up.

ON JABORANDI.

By SIDNEY RINGER, M.D., Professor of Materia Medica and Therapeutics in University College, London; and
W. MURRELL, L.R.C.P.

SINCE a paper published in conjunction with Mr. Gould, the present writers have made ninety-four additional observations on the effects of jaborandi. The results, whilst confirming the previous statements, add a little to our knowledge of the action of this interesting drug. We gave the medicine sixty-eight times to patients, who took it at their own homes at bedtime. In fifty-nine instances, both perspiration and salivation occurred; in five, perspiration without salivation; in four, salivation without perspiration; thirteen complained of pain over the pubes, often very severe, with a strong desire to pass urine; thirty-one experienced pain in the head, often accompanied with giddiness and dulness.

On seventeen occasions, we gave the drug at nine o'clock in the morning, in a warm room, before a large fire. Of these cases, both perspiration and salivation occurred in eleven; in two, perspiration without salivation; in one, salivation without perspiration; three experienced pain over the pubes; six felt severe pain in the head; six nausea or sickness; and, in one instance, the drug caused a good deal of drowsiness; in four cases, the sight became affected; and finally, in three cases, the jaborandi produced no effect. On nine occasions, we gave the drug to patients who immediately left the hospital and returned home, during the late severe weather. Both perspiration and salivation occurred in eight cases; in three, pain over the pubes; in six, severe pain in the head; in four, nausea; in six, much sleepiness; and, in one instance, the drug produced no effect.

In by far the greater number of observations, both perspiration and salivation were profuse; but sometimes the perspiration or the salivation or both were only slight. The observations were repeated several times on certain individuals, and we found that the effects of the drug varied considerably, not only on different people, but even in the same person. Some yield with difficulty to the drug, and require a large dose, even ninety grains of the leaves. In others, whilst exciting considerable perspiration, it affects the salivary gland but little, or not at all; on the other hand, in some it excites profuse salivation, but scarcely affects the perspiration. In respect to its influence on the brain, the sight, the urinary organs, the effects of jaborandi are even still more uncertain.

As might be anticipated, cold exposure, and food influence the effects of the drug. Thus it acts less freely on the skin of persons dressed or exposed to cold; moreover, when administered on a full stomach, the drug is more slowly absorbed, and its effects are less marked. In experimenting, therefore, on persons dressed or exposed to the cold, we were obliged to give a larger dose to get the desired effects. The pain over the pubes was often very severe, especially on two occasions, when it was felt across the navel and passed downwards along the penis, and down the urethra. With few exceptions, the pain subsided immediately on passing water. The headache was generally referred to the forehead over the eyes, though sometimes it involved the whole head, and on one occasion was limited to the left parietal region. The character of the pain was generally dull; most persons calling it a "weight over the eyes". In one case, it was paroxysmal. When the drug was given in the daytime, the pain lasted from half an hour to several hours. Giddiness and a stupid feeling were often associated with the headache. This effect on the head, we believe, has before not been noticed. On

two occasions, where the headache and the pain over the pube were very severe, so severe as to make men complain loudly, we injected hypodermically 1-100th of a grain of atropia, and in a few minutes the pain ceased, showing that probably the antagonism of jaborandi to atropia applies to the effects of these remedies on the head and bladder. To nine persons we gave a dose each night, varying from four to fourteen times successively, and found that the effects of the drug were undiminished by repetition. In all the foregoing experiments, we employed a tincture of jaborandi, a drachm of which corresponds to thirty grains of the drug; we gave two drachms of this tincture, and, on a few occasions, to persons who were dressed, three drachms.

We have carefully watched the effects of jaborandi on the circulation, and always find that it increases the frequency of the pulse, and, except when the pulse is frequent from fever, we have never seen this drug lessen the frequency of the beats. Mr. Langley finds that jaborandi reduces the frequency of the heart's action in animals; hence we must conclude that, in this respect, it affects man differently from animals. Mr. Langley expresses a caution against its use, owing to its depressing effect on the heart; but though, in our numerous experiments, the patient has sometimes become rather depressed, yet we have never witnessed, even after large doses, any very marked amount of weakness.

HISTORY AND MEANING OF THE TERMS DIPHTHERIA AND CROUP.

By SIR JOHN ROSE CORMACK, M.D., F.R.S.E.,
Physician to the Hertford British Hospital, Paris.

AT page 507 of the JOURNAL for April 17th, Dr. William Cumming of Edinburgh begins a note on "Croup and Diphtheria" by thus expressing himself. "The question as to the identity of membranous croup and diphtheria is worthy of the attention it has recently received; but I confess I have some difficulty in understanding how the two diseases can be ranged under the same category." This sentence shows that the same words are at present being employed with different meanings in the discussion to which Dr. Cumming refers. I have read that discussion up to date, and it has appeared to me to derive much of its confusion from the controversialists not attaching the same meaning to the terms croup and diphtheria.

With Dr. Cumming, I hold that membranous croup and diphtheria are not identical; and yet I am not sure, from the drift of his letter, whether he accepts in their integrity the views now almost universally adopted by French physicians, clearly laid before the Pathological Society of London in 1865 by Dr. R. H. Semple, and which I have for many years considered true beyond even the possibility of doubt. My present object, however, is not to enter the lists as a controversialist, but simply to try to clear the field of debate by making a plain statement as to the history and signification of two words.

Diphtheria (with Bretonneau, Trousseau, Semple, George Johnson, and others) I look upon as a malady *sui generis*—as a contagious specific general disease. The leading characteristic of diphtheria is a specific exudation upon mucous surfaces, wounds, and cutaneous abrasions. This specific exudation constitutes the false membranes which we may meet with on the mucous membrane of the pharynx, larynx, trachea, nares, and vagina, as well as around wounds and on cutaneous abrasions. We often see the membrane form on the edges of the tracheotomist's incision in diphtheritic croup. The diagnosis between diphtheritic croup and the various kinds of non-diphtheritic membranous sore-throat (non-diphtheritic membranous croup), can frequently be established by applying a small blister to a convenient part of the body, such as the forearm. If the membranous sore-throat be a local manifestation of the general specific disease, that is, of diphtheria, then, and then only, the blistered surface will become covered with false membrane. Confluent herpes of the throat is often mistaken for diphtheritic sore-throat; and the success in the treatment of diphtheria, of which some British practitioners have lately boasted, can only be explained by their having had to do with throat herpes (*herpès guttural* of Gubler), or common membranous sore-throat (*angine couenneuse commune* of Trousseau). Cases of common membranous sore-throat, recovery from which is spontaneous, are often proclaimed as cases of diphtheritic sore-throat. Their differential diagnosis is, nevertheless, easy; but there are cases of confluent herpes of the throat which it is difficult by mere examination to distinguish from cases of diphtheritic sore-throat.

The sum of the whole matter is this: diphtheria is a specific disease, *sui generis*: an usual local manifestation of it is the formation of false membrane on the mucous surface of the larynx and trachea, constituting diphtheritic croup. The use of the prefix "diphtheritic" is necessary,

so long as the word "croup" is retained, to prevent mistake as to the nature of the affection spoken of; without the explanatory prefix, the word croup is ambiguous, being often employed as a general designation of all membranous obstructions of the throat, and still farther extended by some to spasmodic laryngeal obstructions. The spasmodic croup of English authors is the *faux* croup of the French.

Confusion is apt to arise in the minds of uninitiated students of foreign medical literature when they begin to compare French and German authorities on diphtheria and croup. To avoid bewilderment, it is necessary to bear in mind that the physicians of France and Germany respectively attach absolutely different meanings to the words diphtheria and croup.

The great majority of French writers, considering the question from a purely clinical point of view, regard diphtheria as a disease which is general, specific, and contagious, specially characterised by the formation on the affected parts of false membranes, which, when removed, are reproduced, and which have a great tendency to extend to neighbouring parts, and to become more or less general. French writers designate all pseudo-membranous laryngeal affections by the name of croup; but some of them limit the use of the term croup to diphtheritic laryngeal membranous exudations.

German writers, on the other hand, adopt a purely anatomical division. Completely abandoning the original signification of the Scottish and Swedish word, by which was simply meant croupy or crowing respiration, they apply the term croupal to all affections which are characterised anatomically by the formation of a fibrinous exudation or superficial false membrane upon a subjacent mucous surface in a state of integrity; hence we find them speaking of croupal nephritis and croupal gastritis. They apply the term diphtheritic to deep or interstitial pseudo-membranous exudations, accompanied by infiltration and elimination of the parts subjacent to the false membrane. An example will make clear the essential difference between the German and French nomenclature. The term croupal pneumonia is generally employed in Germany to designate acute pneumonia with fibrinous exudation (*pneumonie aiguë, franche, avec exudation fibrineux*). Some German authors, looking to the pseudo-membranous and ulcerative character of dysentery, give it the name of intestinal diphtheria.

As to the unfortunate word croup, it would be well to expunge it from British scientific medicine, or be careful to employ it unambiguously, which can always be done by the use of a descriptive prefix such as diphtheritic, herpetic, spasmodic, etc.

The word croup was, I believe, first employed in scientific medical literature in 1765 by Dr. Francis Home of Edinburgh, in his *Inquiry into the Nature, Cause, and Cure of Croup*. Till then, it was only the popular term in Scotland and Sweden for stridulous breathing, for crowing or croupy respiration. An attentive perusal of the cases detailed by Dr. Home leads to the impression, that the epidemic described by him was an epidemic of diphtheria, and identical with that studied by Bretonneau at Tours in 1826, and described by him under the name which he created, diphtheria, from *διφθέρα*, a pellicle. It must always be remembered, however, that, although Bretonneau created the name and indicated the true pathology of the disease, his first work—*Recherches sur l'Inflammation spéciale du Tissu Muqueux, et particulièrement sur la Diphthérie*—published at Paris in 1826, was far from complete. It was, however, a grand unveiling of the truth, and the foundation of one of the most brilliant clinical inquiries which adorn the history of medicine.

The term croup was not vulgarised in France till the publication in 1809 of F. Ruette's translation of Home's *Inquiry*. In the same year, Ruette published at Paris a translation from the English of an account by Starr, in the *Philosophical Transactions* for 1750, of an epidemic *morbus strangulatorius* which he had observed in 1748 at Liskeard, in Cornwall. Ruette blames Home for intentionally omitting to mention the work of Starr. He says that perhaps there was nothing new but the name in Home's admirable description: "On pourra même reprocher à ce médecin (Home), d'ailleurs si recommandable, de n'avoir gardé silence sur Starr qu'afin de nous persuader que la maladie dont il (Home) nous a donné une si belle description était nouvelle, ainsi qu'il le prétend; mais un examen plus approfondi nous convaincra peut-être qu'elle n'a de nouveau que le nom qu'il lui a donné."

In concluding this notice of the history and meaning of the terms diphtheria and croup, I may add that, in the current medical literature of Italy and Spain, I find that croup and diphtheria are employed exactly as in France, with this occasional difference, that, in place of croup, the Italian writers often use the term laryngeal diphtheria.

The guardians of the poor of the city of Exeter have raised the salary of the workhouse surgeon (Mr. J. Woodman) from £80 to £100 per annum.

CLINICAL MEMORANDA.

CROUP AND DIPHTHERIA.

THE short paper of Dr. Cumming of Edinburgh on Croup and Diphtheria is so interesting, that it is to be hoped he will publish *in extenso* some of the cases he has seen as illustrating these diseases, together with some of the *post mortem* examinations.

In the meantime, I must remark that I, for one, entirely agree with him in his diagnostic characters of diphtheria, with one exception, but that is a most important one; namely, the character of the false membrane. He says that it is "ash-grey, friable, in many cases almost pulaceous, and generally soft". Now, the very contrary characters have been displayed by all the false membranes in diphtheria seen by myself, as well as by Bretonneau, Trousseau, Guersant, Bouchut, and a number of other writers and observers, both on the Continent and in this country. They have all described the membrane of diphtheria as possessing the very characters which Dr. Cumming attributes to membranous croup; namely, that it is "firm, tough, tense, and of a light kid colour". It is not possible that the tubular cast of the windpipe, often voided or extracted entire during life, or discovered entire after death, in diphtheria, and often described, can be "friable, pulaceous, and soft".

R. H. SEMPLE, M.D.

TEMPERATURE IN TYPHOID FEVER.

In an address on the Etiology of Acute Specific Diseases, delivered before the Clinical Society of London, Sir W. Jenner controverts the statement of Wunderlich, that "we may exclude typhoid fever when between the fourth and sixth day in a child, or adult under middle age, the temperature does not reach 103.1 deg.", and says that he has found this law to have so many exceptions that, as a law, it cannot be said to exist. Of the correctness of this opinion I have no doubt. I have occasionally had typhoid cases in the Aberdeen Hospital, where about the sixth day the recorded temperature never reached 103 deg.; and when I was at first inclined to think that the clinical clerks were at fault, and had not allowed the thermometer to remain sufficiently long in the axilla.

But, in the spring of 1874, I attended in private practice three cases of typhoid fever in young adults, all occurring in one family. They were all well-marked cases, without complications, and their temperatures were taken very carefully night and morning; but in none of them during the first week did the temperature exceed 102.5 deg. In justice to Wunderlich, it must be admitted he says that "in this pre-eminently typical disease, not a single rule can be laid down which is not subject to exceptions, although these may, as regards some rules, be extremely rare".

There is no doubt, however, that Wunderlich considers the exceptions to this special rule as being extremely rare, while Sir W. Jenner's experience is just the reverse. It would be well if other observers would record their experiences.

J. W. F. SMITH-SHAND, M.D., Aberdeen.

CASE OF PLEURITIC EFFUSION AND THORACENTESIS: RECOVERY.

FANNY H., aged 19, entered the New Hospital for Women as an out-patient, December 14th, 1874. Her family history was phthisical, two aunts having died of phthisis. She had had no acute illness; but had been ailing for four months, coughing and losing flesh, and getting very weak. Till within a day or two, she had been attending at another hospital for "consumption".

On examining her chest, I found the left side, back and front, absolutely dull; the respiratory sounds absent, except at the apex, and those puerile. The heart was displaced an inch to the right of the sternum. The left side of the chest was three-quarters of an inch larger than the right. The dyspnoea was not urgent; respirations were thirty per minute. Decubitus was on the left side, and sometimes on the back. The temperature at 2 P.M. was 101.6; after admission, it was found to be 102.8 at 9 P.M. The tongue was dry and glazed; the gums spongy, and the teeth covered with sordes. The bowels were much relaxed. She had no appetite. The catamenia were regular, but extremely scanty. She was admitted as an in-patient the next day, and three days later I performed thoracentesis with Dieulafoy's bottle-aspirator. Ten ounces of fluid were removed.

At the close of the operation the heart's impulse was felt to the left of the sternum. No attempt was made to remove all the fluid. The subsequent progress of the case was one of unbroken recovery. The remaining fluid was gradually, and not very slowly, absorbed; the symp-

toms of hectic disappeared, and the patient was discharged on February 22nd, 1875, in good health, with good respiratory sounds to the base of the left lung, with the heart in its normal position and with but very slight retraction of the left side.

The main interest of this case seemed to me to lie in the extremely unpromising character of its symptoms before the operation. It would, I think, be difficult to have a case of pleuritic effusion in which there was more reason for hesitating before deciding to operate. With a phthisical history and phthisical symptoms, with hectic and extreme general prostration on the one hand, there was on the other no such urgent dyspnoea as required the operation for immediate relief. The case seemed to be one in which not very much could reasonably be hoped from the operation of thoracentesis. The two considerations which decided me in favour of operating were these—the apparently sound state of the right lung, which was, to some extent, evidence against advanced disease in the left lung, and the possibility of the hectic being due to emphysema. Dr. Broadbent was kind enough to see the patient with me, and to give me the benefit of his assistance and advice at the operation and before it.

ELIZABETH GARRETT-ANDERSON, M.D.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

BETHLEM ROYAL HOSPITAL.

PERITYPHLITIS ASSOCIATED WITH ACUTE MANIA.

(Under the care of Dr. W. RHYS WILLIAMS.)

[Reported by G. H. SAVAGE, M.D.]

F. W. W., aged 23, a clerk, with no family history of insanity, who had always enjoyed good health and been of temperate habits, was, seven weeks before admission, suddenly seized with violent pain in the abdomen, which, becoming worse, confined him to bed. Vomiting came on, which lasted for eight or nine days. His bowels were confined, and his abdomen became very much distended. The vomiting ceased and the swelling subsided, and he appeared to be getting better, but was noticed to be extremely weak. At this time, about eleven or twelve days after the onset of the attack, he became excited, would jump out of bed, and swear at his friends; he was so violent he had to be held in bed by two persons; he fancied persons wanted to murder him. On admission into Bethlem, he was extremely weak and had to be kept in bed; he was emotional and nervous. He had some exalted ideas, but these were very transient; he was extremely variable, and would talk in a rambling way for a time. There was a large, hard, inflamed mass over the cæcum; his bowels were confined; he had no vomiting. After a few days, he improved steadily in general health, but still he could not control himself. He said it was too much trouble to talk, or even to think, and that if he tried he became confused, and this excited him. In another week, he was up and about the ward, but still fidgety and unable to settle to any amusement or employment. A month after admission, his general health being re-established, he had a slight renewal of the inflammation of the cæcum, but this passed off, and he gradually convalesced, and was discharged well ten weeks after admission.

Mania following acute disease is not uncommon, and must generally be considered as caused by exhaustion. Such cases are generally excitable and irritable; the controlling power seems to be lost. During the past year, there have been at Bethlem some cases following scarlet fever, in which suspicion and irritability were the most marked symptoms. Very many cases of the most acute mania are found associated with great anemia, and tonics rather than depressants are indicated. At Bethlem, there have been recently under treatment cases of mania of the most violent type following pneumonia and also menorrhagia. In such cases, the maniacal symptoms usually supervene a week or more after the height of the acute disease.

GLASGOW WESTERN INFIRMARY.

COLLOID CANCER OF OMENTUM.

(Under the care of Dr. FINLAYSON.)

[Reported by C. J. PLUMER, M.D.]

Ascites, without Dropsy elsewhere: Slight transient jaundice eighteen months ago: Habits temperate: Consolidation of Apex of Left Lung with

moist Riles; 268 oz. *Bloody Serum Removed by Aspirator*; *Superzention of Deep Jaundice with Pale Stools*; *Second Tapping, allowing hard masses to be felt through abdominal walls*; *Severe Vomiting, Pain, and Prostration*; *Death*. *Section: Colloid Cancer of Peritoneum, chiefly of Omentum, pressing on Portal Vein and Common Bile-Duct*; *Numerous Stones in Gall-Bladder*; *old Atrophic Lesion of Left Lung, with considerable Emphysema*. *Remarks*.—Ann C., aged 37, was admitted into the Glasgow Western Infirmary on January 11th, 1875, complaining of swelling of the abdomen, with some pain in the right side, of six weeks' duration. She was the mother of nine children, and her health had generally been good till eighteen months ago, when she began to suffer from pain in the right lumbar region, with vomiting of food and of a dark bitter fluid; this was associated with a yellow discoloration of the skin and with general weakness. She was at that time treated in the Royal Infirmary for six weeks, and left much improved, and was confined of a healthy child at full term six months afterwards. After this, her health continued fairly good, although she was never so strong and healthy as before her illness; and had more or less pain in the right side. Seven weeks before her admission to the Western Infirmary, the urine became scanty, high coloured, and turbid, and in a few days the abdomen began to swell, and the pain shifted from the lumbar region to the margin of the ribs in the line of the right mamma. She had no vomiting at this time, but the bowels were obstinately costive; her appetite was bad, and she had lost flesh. The catamenia had not appeared since her last confinement, eleven months before. She complained, on admission, of a constant pain in the right side, with occasional severe exacerbations; the abdomen was found moderately distended with fluid in the peritoneum; the area of the hepatic dulness seemed rather less than normal; the urine was scanty (nine ounces in the twenty-four hours), specific gravity 1032, with a deposit of urates, but free from albumen. In the chest, there was some dulness at the base of both lungs behind, with diminished vocal resonance and fremitus. Subsequently (February 14th), there was noted a marked dulness under the left clavicle, with bronchial breathing and moist riles. There was no dropsy except of the abdomen, and the vaginal examination gave negative results.

Treatment by a variety of diuretics, etc., having failed, purgatives were tried, but with no better result. The distension increased, and vomiting became troublesome, the appetite became even worse, and emaciation became more marked. Two hundred and sixty-eight ounces of fluid were removed on February 19th by the aspirator; this was clear, but had a light red (bloody) tint generally diffused through it; it was of specific gravity 1020, faintly alkaline in reaction, loaded with albumen, and showed under the microscope abundant blood-discs and a few exudation-corpuscles. Examined immediately after the tapping, the liver could be felt within the costal margin, and it was evident that it was not enlarged; no distinct tumour could be felt in the abdomen. The tapping gave temporary relief: the next day the urine was found to contain a considerable quantity of albumen, and pus and blood-corpuscles were found in the sediment. (This albuminuria was quite temporary.) The urine continued scanty, the bowels very costive, so that scammony or enemata were frequently required, and the vomiting persisted. On February 26th (seven days after the tapping), it was noted that the conjunctivæ and skin were slightly yellow; and on March 1st, decided jaundice was present, the feces were pale, and the urine deeply tinged with bile. The patient now became worse; nearly everything was rejected by the stomach soon after it was swallowed, and severe pain in the middle of the back and about the epigastrium began to be complained of. The temperature, which since admission had seldom been much, if at all, above the normal, became elevated, and reached 100.6 deg., 101.2 deg., and even 102 deg. Fahr. The distension had increased so rapidly, that paracentesis was performed for the second time on March 14th, when 360 oz. of fluid were drawn off; this had the same characters as before, but, in addition, was highly tinged with bile. An examination of the abdomen immediately after this tapping, again showed that the liver was not at all enlarged; but an irregularity existed just below, and, to the right of the xiphoid cartilage, in the situation of the chief pain and tenderness complained of; numerous hard masses could be felt both above and below the umbilicus, but chiefly in the situation of the colon, and they suggested the notion of scybala in the bowel. No albumen appeared in the urine after this second tapping. From this time, the patient gradually sank, the jaundice remained intense, vomiting was persistent, and death occurred on March 27th, the pain and excessive languor complained of during the last few days of life being relieved by hypodermic injections of morphia.

Necropsy.—The abdomen contained a large quantity of fluid similar to that removed at the last tapping, but a considerable number of soft gelatinous masses of yellow colour came away with the fluid. The great omentum was found to be occupied by an immense mass of orange

yellow colour, hard in some parts, very soft in others, and very irregular in its surface; the mass appeared at some points to be made up of small nodules, but for the most part these had coalesced with an indiscriminate growth; in some parts, the omentum was thus thickened to the extent of fully two inches; the omentum thus changed could be raised up from the bowels below, there being no adhesions. In addition, the lesser omentum, the mesentery, and the peritoneum generally, including the surface of the liver and certain coils of intestine, were the seat of innumerable gelatinous growths, in some parts isolated, in others coalescent. The parietal peritoneum was likewise thickened throughout, and presented the same yellow aspect as the omentum, with numerous spots of ecchymosis and small adherent clots of blood. The suspensory ligament of the liver was converted into a large mass resembling the thickened omentum; this corresponded in position with the site of the pain and the irregularity felt during life. The viscera, having been removed in a mass, were subsequently examined by Dr. Joseph Coats; he found the gall-bladder, towards its neck, to be the seat of a bulky tumour projecting into its calibre and completely obstructing the neck and the duct; the ductus communis was partially obstructed, but free towards the duodenum; the hepatic duct likewise was partially obstructed, but free towards the liver. The walls of the ducts were much infiltrated, and a yellow gelatinous material projected from their internal surface; they were also buried in a gelatinous mass. The gall-bladder was distended, and contained six large and about fifty small pale calculi. The liver was infiltrated with bile, and its tissue very soft, but the organ was not increased in size. The portal vein was distinctly compressed by the growth; but the vena cava seemed quite free from pressure. The stomach was normal. The lungs were slightly adherent generally, the left completely so at the apex; the tissue of this part was condensed and somewhat cheesy, and had a collapsed aspect, while large emphysematous patches existed at the margins. The heart, kidneys, and other organs presented nothing remarkable. Dr. Coats examined the growth microscopically, and found the typical characters of colloid cancer; he was of opinion that it had originated about the neck of the gall-bladder or its duct.

REMARKS BY DR. FINLAYSON.—This case was of peculiar interest, and presented considerable difficulties. The diagnosis was correctly made as regards, perhaps, the essential lesion, but, owing to the misinterpretation of one point, an important omission occurred. When the patient was first shown to the clinical class, the signs of peritoneal effusion were plain enough, and were easily verified by the students, and the probable causation—portal obstruction or chronic peritoneal disease—was then discussed. Cirrhosis of the liver seemed rather improbable, owing to the clear absence of intemperance in this woman's case; but some suspicion was thrown on the liver from the occurrence of slight jaundice about eighteen months ago, during her previous illness in the Royal Infirmary. On the other hand, some suspicion of chronic peritonitis, with effusion, arose from the existence of indubitable signs of consolidation at the apex of the left lung; this was associated with moist riles, but the absence of any serious febrile disturbance induced much hesitation in the diagnosis of tubercular disease in the chest and abdomen. When, from increased tension, tapping had to be performed, the bloody character of the fluid again suggested peritoneal disease, although in a case which I recorded lately in this JOURNAL (January 2nd, p. 10), a bloody exudation in the peritoneum was found in a typical case of cirrhosis of the liver. In a few days after the tapping, however, the occurrence of jaundice seemed to stamp the case as hepatic. Careful observation, made immediately after the tapping was completed, satisfied me that the liver was certainly not enlarged, and no tumour could be felt in the abdomen, except a cord-like thickening in the region of the gall-bladder; this was the only, or at least the chief, seat of pain throughout the case, and the dissection showed it to be due to a thickening of the suspensory ligament of the liver. The jaundice was evidently due to obstruction, and was much too deep to be explained on the theory of cirrhosis, but its persistence, and the rapid reaccumulation of the peritoneal fluid, seemed, in the absence of hepatic enlargement, to point pretty plainly to some tumour, probably cancerous, obstructing the portal vein, and by its extension leading to compression of the common bile-duct. Immediately after the second tapping, a new feature was developed in the remarkable sensation experienced on examining the abdomen. A large number of hard masses could be felt which were, so far, movable, and seemed to follow the course of the different parts of the colon; and, as the bowels had been very difficult to act on, and the motions had often contained many scybala, it was too hastily concluded that these hard bodies were intestinal accumulations. Accordingly, enemata and purgatives were administered, and they brought away some hard feces; this further misled the diagnosis, for by this time the fluid had accumulated again so as to place the nodules and the intestines beyond reach. This sensation, however, was, no doubt, chiefly due to the cancerous masses found

after death in the omentum ; for, although some hard feces existed in the bowels even at the *post mortem* examination, the cancerous nodules were particularly prominent in the omentum just at its edges, where it followed the course of the colon.

The two facts referred to as complicating and confusing the diagnosis—the previous occurrence of jaundice and the consolidation of the left lung at its apex—seemed to be, as it were, mere accidental coincidences ; the previous attack of transient jaundice eighteen months ago rather militated against the cancerous theory of the present illness ; the discovery at the dissection of numerous stones in the gall-bladder afforded a clue to the cause of the former attack. The occurrence of jaundice as a new symptom in a disease which seemed to be extending (as judged by the rapidity with which the fluid accumulated) could scarcely, it was thought, be due to a separate lesion ; and the characteristic pain of hepatic colic was absent, so that this previous attack of jaundice was not allowed to influence the diagnosis. For similar reasons, the pulmonary lesion sank into insignificance, for diagnostic purposes, on the occurrence of jaundice, and on dissection it seemed to be a very old atrophic lesion not specially related in any way to the fatal illness.

SELECTIONS FROM JOURNALS.

PATHOLOGY.

PATHOLOGY OF THE SYMPATHETIC NERVE.—Pio Foa, in a memoir published at Bologna, describes the results of the researches made by him on the state of the cervical and semilunar sympathetic ganglia in one hundred and forty persons who had died of various diseases. Changes of very various natures were found, among which the most important were : simple atrophy from compression, or marasmus ; atrophy with complete fibrous degeneration ; simple hyperæmia or congestion, sometimes combined with sclerosis ; accumulation of white corpuscles, amounting even to true suppuration ; pigmento-fatty infiltration and degeneration ; amyloid degeneration ; and micrococci in the blood-vessels. In tuberculosis, the vessels of the ganglia were often dilated and overfilled with blood. Where tubercular disease of the abdominal organs predominated, the ganglia were anæmic and atrophied ; and, where the course of the disease was very acute, the blood-vessels were crowded with white corpuscles. After inflammation of the lungs, and in cases of heart-disease, the ganglia were overloaded with blood and strongly pigmented ; in leukæmic conditions (lymphatic leukemia), the white corpuscles were present in abnormal quantity. Syphilis was accompanied with a remarkably copious development of connective tissue and by pigmentation of the cells ; in profoundly cachectic states, there was amyloid degeneration of the vessels of the ganglia ; in pellagra, the vessels were much dilated, and the cells were full of pigment and fat ; and, in infectious diseases, there was an abundance of white corpuscles in the stroma.—*Centralblatt für die Medicin. Wissenschaften*, March 20th.

MEDICINE.

DEATH FROM PERFORATION OF THE APPENDIX CÆCÆ.—The following case is related by Dr. R. F. Noyes of Providence, Rhode Island. The patient, a male, aged 31, was taken with severe pain in the right iliac region. The tenderness and pain were augmented by pressure. He had previously eaten raisins. The constitutional symptoms were not marked ; the bowels were confined. Dr. Noyes kept him under the influence of morphia ; but the pulse became accelerated and the abdomen tympanitic. Sinapisms and turpentine stupes, and hypodermic injection of morphia to relieve the pain, were used from the first. When he began to sink, iced champagne and brandy were given freely, by mouth as long as possible, and then by rectum, and lastly hypodermically ; but all was in vain. He had stercoraceous vomiting. He died from asthenia. Dr. Noyes made the diagnosis of peritonitis and accumulation of irritating material at the ileo-cæcal valve, but was agreed in by three physicians who saw this case with him. At the necropsy, plastic material was found upon the small intestines, causing adhesions here and there, but there were no bands producing occlusion of the bowels ; there were pus and other fluid in the peritoneal cavity. In the appendix cæci was a mass of fecal matter as large as a cherry-stone, in the centre of which was a raisin-seed. At the point of union of the appendix with the cæcum was a perforation of the bowel allowing the contents to escape into the peritoneal cavity. When the abdomen had become enormously distended with flatus, with the consent of the physicians and surgeons in consultation, Dr. Noyes plunged a needle $1\frac{1}{2}$ millimètres in diameter into the transverse colon, and allowed the gas to escape, whereupon the abdomen became more flaccid, and the respirations fell from twenty-six to twenty in a minute.—*Detroit Review of Medicine*, January 1875.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, APRIL 24TH, 1875.

PUERPERAL INFECTION.

THERE are few diseases more important in the range of medicine or surgery, or more opportune for present discussion, than puerperal fever, whether we view it from a scientific point of view, or from its medico-legal bearings. The subject is one that has of late attracted much attention with the public and the profession, and will continue to do so for some time. The prosecution of two midwives lately for conveying the poison to parturient women, and the conviction in one case, has rendered the subject one of vital importance to general practitioners. As we pointed out at first, the doctrine of "manslaughter by infection", once formally accepted in the law courts, cannot be lightly dismissed. Time will prove whether the medical men in those two cases were wise in driving matters to extremes, and forcing on a prosecution. It cannot be expected that medical men will escape unscathed, and we should not be surprised to hear of medical men before long being similarly charged, and prosecutions instituted, either from conscientious motives on the part of the relatives, or else, we are ashamed to add, from motives of gaining money. In a case of which we were recently cognisant, the husband claimed a pecuniary consideration for alleged neglect of his wife, at a charity, on the day after death ; his motives were apparent, and the claim failed. The majority of such cases will happen amongst the poor ; and by the wide dissemination of cheap and sensational literature, these last cases are made known far and wide. Already we have had one correspondent writing, and strongly deprecating a recent inquest, on account of the injury inflicted upon him.

Puerperal fever seems to have been of late very prevalent over the country. We have heard of epidemics in various towns, chief amongst which we may mention Coventry, Wolverhampton, Oxford, Stockton-on-Tees, and in several districts in London ; besides which, judging from letters which we have received, and have published, from time to time, under pseudonyms, such as Obstetricus Junior, etc., there are vague hints at similar conditions in other quarters, but the writers have been afraid to state their true names, on account of the injury likely to arise to their practice. Nor are the returns in the Registrar-General's report likely to give a correct idea as to the amount of puerperal fever throughout the country, as it is stated to be a well known fact, that some practitioners have such a dread of its becoming known that they have had any cases of this disease in their practice, that they return the causes of death under such headings as peritonitis, pyæmia, and septicæmia, to avoid attracting attention. It is but quite lately that a gentleman wrote to us, stating that in his own particular neighbourhood he was aware of not fewer than eight deaths from puerperal fever in the practice of one man ; and yet, on searching the district records, not a single death from that cause could be found. This is not peculiar to England. The latest outbreak of puerperal fever that we have heard of is at Crewe, where it is stated the parish medical officers have lost no fewer than eleven cases, besides several more returned under the name of peritonitis and pyæmia, all within a period of three weeks. The case is creating great excitement in the neighbourhood, and much anxiety on the part

of expectant mothers. We believe, however, there is a great deal of exaggeration in current statements.

The matter has been taken up by the Board of Guardians, and it is intended to petition the Local Government Board to send down an inspector to investigate the matter. The result of an investigation by the Local Board of Health is, however, to decline to ask for such inquiry. The reports, it is stated, are much exaggerated; and it is alleged that due precautions were taken from the first. The *Liverpool Courier*, in commenting upon this case, does not forget to remind the public that midwives have been lately tried for recklessness in conveying the poison to parturient women.

The discussion now taking place upon puerperal fever before the Obstetrical Society, upon a paper read by Mr. Spencer Wells, could not, therefore, have occurred at a more opportune time. The views expressed and the decisions come to will be read with the deepest interest by the profession, as there can be no doubt that, if medical men are to be prosecuted as midwives have been, the theories there propounded, and the conclusions arrived at, will not pass unheeded, either by prosecutors or by defendants.

In bringing the matter before the Society, Mr. Spencer Wells, in order to obtain some decisive opinion on the subject, reduced the substance of his paper into six categorical questions. This seems to have escaped the attention of the gentlemen who spoke at the last meeting; at least the majority omitted to answer Nos. 4 and 6, which were very practical questions. Dr. Leishman, who spoke first, disclaimed his recent published views on puerperal fever being a fever *sui generis*, and regretted he had not more thoroughly investigated the evidence of the pyæmic or septic origin of the disease; at the same time, he doubted whether it would be a solution of all the difficulties. Dr. Newman of Stamford disbelieved in a definite puerperal fever, as, in every case that had come to his notice, either directly or indirectly, he had been able to trace some distinct infecting poison as the cause. He laid great stress upon the mental condition, as predisposing the system to the development of septic poisons, however introduced. In a large proportion of his cases, these causes were in operation.

Dr. Braxton Hicks considered that the observations of the older writers, which were made principally in hospitals, tended to retard the investigation of the disease, and that it could best be studied clinically in the private homes of patients. He drew attention to his already published eighty-nine cases of puerperal fever, which showed a large proportion of them were connected with animal poisons; when the origin could be traced to a decomposing "sepsis," washing out the uterine cavity was of great value. The effect of the scarlatinal poison on the puerperal woman was not altogether to be measured by the mortality, as only one-third died; whereas the other two-thirds made bad gettings-up, from pelvic cellulitis or other uterine mischief retarding involution. Whether all forms of puerperal fever were contagious to the puerperal woman, he could not say; but he was certain that all were not so liable to be conveyed by the attendants. The zymotic fevers he considered the most infectious. Mr. Jonathan Hutchinson recapitulated his well-known views upon erysipelas and pyæmia, regarding them not as specific diseases, but as the effects of local forms of inflammation, the patient being poisoned by the results of inflammation of his own tissues; and he regarded puerperal fever as a similar condition. Dr. B. W. Richardson drew special attention to the peculiar physiological condition of women after delivery—how that the blood contained more fibrin, a diminution of the salts, tending to the formation of coagula on a slight rise of temperature. He divided puerperal fever into four forms: first, an exaggeration of simple surgical fever, or fever of "resistance," as he styled it, where a sudden rise of temperature causes coagulation of the fibrine in the right side of the heart; secondly, the bilious fever; thirdly, the autogenetic; and lastly, a puerperal fever arising from poison conveyed into the body from without, not,

perhaps, a poisonous secretion at all—poisonous only in its individual sense, but not poisonous as coming from any person who has been poisoned. He believed that, before long, a means would be discovered which would effectually prevent septicæmic poisonings, as vaccination did small-pox. On the question of the value of antiseptics he had nothing to add to Dr. Braxton Hicks's suggestion of washing out the uterus.

In the further discussion that is to take place on the 5th of next month, we should like to hear more of the etiology of the disease, and the mode of its propagation, as also the precautions necessary to prevent its spreading. The individual experience of our readers, although perhaps limited to isolated cases, would be of immense importance, as in these cases there is greater likelihood of its origin being traced, and the means adopted for the prevention of spreading more clearly known. It would be very desirable to know the exact forms that are contagious, the mode of their propagation, and the laws that seem to regulate the dissemination of the poison; as also the best means to adopt to disinfect the propagation of the poison when it is conclusively known it is the purveyor of the disease. We invite communications from our readers.

Again, what length of quarantine is necessary, if any? how is that quarantine best carried out? what disinfectants are the best? and how is that exceedingly tenacious form of the poison to be eradicated? Does the poison become endemic in the dwelling of the attendants, clinging to the bedding and rooms like the fomites of scarlatina, and re-infecting the individual although his ordinary apparel is changed or thoroughly purified? or is it that the individual retains the poison within his system, and, in fact, is labouring under the influence of a most subtle poison, although apparently in the best of health?

We wait with interest the views of accoucheurs upon these and various other matters.

VOTING AT THE MEDICAL BENEVOLENT COLLEGE.

THE voting papers for the election of candidates for the benefits of the Royal Medical Benevolent College have been received this week. They contain a printed notice, to the effect that subscribers who wish to be freed from the annoyance of being canvassed should forward their names to the committee, with a view to their names being placed in a separate list. This may be taken as a first result of the largely signed memorial presented to the Council, praying them to relieve candidates from the hardship imposed upon themselves, their relatives, and friends, by the present method of electing by the voting system. We cannot, however, consider that this is any other than an illusory mode of meeting the question. It grants no real reform; it does nothing to secure justice to the most deserving candidates, or to improve the tribunal by which judgment is given in favour of any particular applicant, or against others whose necessities are more cogent, but whose friends are less influential, whose means are more wholly exhausted, or whose cunning in canvassing is less developed. Charity electioneering is one of the oddest and most anomalous forms of alms-seeking which has ever sprung up among us. It is a caricature of local self-government, which reproduces all the defects of that institution without any of its merits; it is a wild parody of charity which could never have existed, and could not now survive, but that it affords scope for some of the most common weaknesses and vanities of human nature, and is capable of being defended by the misapplication of platitudes which have a traditional attraction, and retain their influence even when they have lost their meaning.

If any one were to propose to a charitable person plainly that his bounty should be distributed—not to the most necessitous object of it, not to that case which most completely fulfilled all the conditions which it was intended to satisfy, not to the poorest offspring of the most helpless widow—but to the child of the most powerful, to the *protégé* of the most active canvasser, to the case pushed by those who had most friends and the largest purse, such a proposition would be rejected with

scorn. If it were to be suggested that the best test of the wants of a widow or an orphan were that either she or her friends should spend, say, a hundred pounds in postage and printing, and several months in personal solicitations, no one would approve it, not even, we think, the Postmaster-General or the local printer, who alone benefit by it. If it were proposed that a candidate who "failed" at first, possibly because other cases were more deserving, should go on adding each year the votes he got on a previous occasion, on perhaps false representations, to those which he gets the following year on equally insufficient or incorrect statements, until at last accumulated expenditure and persistent mendicancy gain a prescriptive superiority over pressing necessity, this would be felt to be a mockery of reason and a falsification of charity. All these monstrous principles, however, are involved in the system of voting at charities. There is nothing to guide the voter except the statements of the candidates, who say what is most telling, and conceal what is most damaging to their canvassing. There is no impartial examination of their respective claims; barely any examination at all. Every card bears the names of certain more or less well-known friends, which seem to authenticate the existence of the person for whom aid is sought, and roughly the preliminary facts stated. That such authentication is not enough to prevent even the grossest fraud, was proved by the case of Dorrington, whose imposture at the Incurables Hospital was the subject of accidental exposure in the police-court. It is not apparently denied, and Mr. Manby is the authority for the statement, that a lady with an income of six hundred a year succeeded in obtaining election for one of her children at the Royal Medical Benevolent College, notwithstanding that the fact was not altogether unknown to members of the Council. But apart from cases of gross fraud, or of serious omission or misrepresentation, it is certain that the names appended to a card do not imply an impartial examination of all the facts. They imply only a friendly endorsement of *prima facie* claims. Most often the husband was known during life, and the rest is taken to be true exactly as told, upon the faith of verbal statements. In any case, the examination is not comparative or judicial. There is nothing to guide the voter except the urgency of the application and the number of friends who write to him. Few men, perhaps, reserve their vote to the end. At least three-fourths of the votes are pledged early in the year on the application of friends.

What is the cost of a successful canvass of the governors of the College? It is variously estimated. One lady writes that, had it not been for the help of "an influential member of the Council", she could never have succeeded in getting her little boy into the College, although, she adds, "I spent more than £60 in the canvass, and am still paying it off to friends who lent me the money".

No one can for a moment doubt the extravagance, the inefficiency, of election by canvassing; the cost of time, money, and anxiety to candidates; and the certainty that wide connections and influential friends will carry the day over obscure but dire necessities. It is, indeed, a method which practically disfranchises want and suffering, and leaves the poll at the mercy of influence, wealth, and activity. A shade of responsibility rests upon every voter; but, when responsibility is divided into fractional thousandths, it is very little felt. The same man who would be scrupulous to fulfil most carefully the great trust devolved upon a committee of selection, feels little the responsibility of giving a six-thousandth vote at the request of a friend who is vaguely supposed to know the merits of a case, although he cannot know anything of its comparative claims.

The device of allowing the names of governors who object to be canvassed to be published in a separate list is a very imperfect and quite useless invention. It is a polite intimation on the part of the Council, which may be roughly paraphrased as saying, "You disapprove of the mode of selection; you see that it affords no test of necessities, and that it involves great waste and practical cruelty. Then clear your conscience by standing aside. We do not propose to alter the mode of selection; but you need take no part in it. Continue to subscribe, and let the evil of which you complain flou-

ish in our hands." Is this reasonable or just? When the country complained of rotten boroughs and bribery at elections, what would have been thought of statesmen who said to the petitioners, "Very well; you do not like the way in which members of Parliament are elected, or that it is calculated to secure the best representatives of the people; then send in your names, and a list shall be formed, and you shall not vote at all; otherwise the same mode of election will be continued as before, and no doubt you will be satisfied"? That would have been a pretty sort of Reform Bill. It is, however, the reform which the Council of the Medical Benevolent College seriously propose.

We do not comprehend what are the reasons which prevent the Council of that noble charity from adopting the same method which has been long in successful operation, with universal approval, in two other medical benevolent societies: the Society for the Relief of the Widows and Orphans of Medical Men, and the British Medical Benevolent Fund. In each, the selection of candidates is made by a responsible Committee. It is so well made that we have never heard one word of complaint. The sole ground of objection to the reform lies, we believe, altogether outside the merits of the question. The annual canvass is considered to be a valuable advertisement for the charity at the expense of the candidates. This is, however, an advertisement which is unjust, expensive, and in every way objectionable. Just as men sometimes are impelled *propter vitendum vitendi perdere causas*, so charitable institutions which do that which is uncharitable and unjust, and make the efficient and merciful distribution of alms secondary to the gathering of more ample means for almsgiving, must be said to sacrifice the end to the means, and to inflict the wound which they are intended to heal. As a matter of fact, we believe that the theory that injustice of this kind is necessary to the success of an institution is a fallacy. Many great charities are supported in this country, and especially, we learn, also in Scotland, without any such machinery. At any rate, we may be sure that to rely upon a palpable act of injustice as a foundation of success is to build upon a quicksand. We earnestly hope that the Council will reconsider this subject; and that, just as medical men have approved free hospitals without the *quid pro quo* in the shape of letters, just as they have exposed the costly annoyance and degradation of canvassing for medical offices in hospitals and have in most places secured the substitution of a committee of selection, so they will speedily put an end to the extravagant, degrading, and inefficient system of electing scholars and pensioners at the Royal Medical Benevolent College by indiscriminate canvassing.

A NEW ophthalmic hospital is to be erected in Sheffield, at a cost of £13,000.

SIR DUNCAN GIBB, we are sorry to hear, is seriously ill.

THE Prince of Wales has graciously consented to become patron to the West London Hospital.

THE Central Association of German Dental Surgeons will hold its fourteenth annual meeting at Freiburg in Breisgau, on August 2nd, 3rd, and 4th.

THE Academy of Sciences in Stockholm has formed a committee for the purpose of carrying out a proposal to erect a statue to the celebrated botanist Linnaeus, to be unveiled on January 10th, 1878, the centenary anniversary of his death.

THE Clerk of the Peace for Surrey has been instructed to acquaint the Boards of Guardians of the county that it is the intention of the magistrates to provide further accommodation for pauper lunatics, and a committee has been appointed to make the necessary arrangements for carrying their intention into effect.

THE *Gazette des Hôpitaux* of Paris publishes a translation, by Dr. Darin, of the able report by Dr. Julius Althaus on modern medical electric and galvanic instruments, which appeared some time ago in the BRITISH MEDICAL JOURNAL, and which has since been reprinted as a pamphlet.

AMONG many good stories which must be put to the credit of Sir Dominic Corrigan, is one of a lunatic who used to complain of the difficulty which he had in keeping the peace between his two legs. One, he said, was Catholic, and the other Protestant; and they were always knocking each other about, especially when they should have been at rest in bed. Sir Dominic advised him to tie them up together, and so enforce their keeping the peace. Next morning, he inquired the result. His expedient had only made matters worse. They had resented the enforced proximity, and, said the unhappy man, "they nearly tore each other to pieces. They gave me no rest; and I had at last to unloose them, though I had promised you to give your plan at least one night's trial." Sir James Paget has tried Sir Dominic Corrigan's expedient in his last modification of the "conjoint scheme", and with no better success. To meet the tardily discovered difficulties of the College of Surgeons in carrying out the scheme so far as relates to the mode of electing examiners, he had proposed that the College of Surgeons should elect the surgical examiners, and the College of Physicians and Society of Apothecaries certain other of the examiners. This has, it seems, given great umbrage to some of the Fellows of the College of Physicians, who had always been a little shy of acting with the Society of Apothecaries as joint electors of examiners. In the very clear and accurate account which Sir George Burrows, in the course of the able address which we print in another column, has given of the negotiations for carrying out the conjoint scheme, he hints at the possibility of the scheme breaking down. If it do break down, the intervention of the Government will, as he points out, be a necessary and imminent means of cutting the knot; and, all other difficulties being settled, the precise cause of the break-down will be, we believe, this little difficulty about the mode of electing examiners. Such a knot seems hardly worthy of the sword of imperial power, and we are inclined to hope that the Colleges will still find means to untie it. The College of Physicians was, we believe, originally willing that each of the three bodies should separately elect a quota of examiners; and the fact that Sir James Paget has unwittingly tied together the College of Physicians and the Society of Apothecaries in a joint election need not, we imagine, form an insuperable bar to ultimate agreement.

THE College of Surgeons' Bill for "enabling" them to take part in the conjoint scheme, introduced into the House of Commons by Sir John Lubbock, is, we believe, safe. The Government have assented to it, and it has passed its second reading. Mr. Stansfeld will, it is stated, however, insist that a clause shall be inserted providing that nothing in this Bill shall operate to deprive women of any right which they may already possess to require the College to admit them to examination for a surgical diploma. A similar proviso was inserted last year into the Apothecaries' Society's enabling Act; and it is understood that it will not be resisted in this case also. On the other hand, Mr. Cowper-Temple's Bill for registering the medical degrees of certain named foreign Universities when obtained by study and examination abroad by women, will be opposed by Government and by the profession, and will have, we consider, no chance of passing. The reasons given in favour of it are rather plausible than solid.

APPROPOS of the General Medical Council, we must express the hope that the supplementary visitations of examinations by the visitors appointed by the Medical Council will be brought to a satisfactory completion, in time to allow the reports to be prepared and circulated as long before the meeting of the Council this year as will enable them to be satisfactorily debated at that session.

THE portion of Sir George Burrows's address which refers to the subject of improved professional remuneration will be read with a good deal of interest. He is led to the subject by a communication from the Shropshire Ethical Branch of the British Medical Association as to the subject of certain kinds of fees, which, he observes, especially concern "the

surgeon apothecary or general practitioner". The general practitioner is now a person whose interests and duties very largely concern the College of Physicians, inasmuch as Sir G. Burrows congratulates the College that it now numbers 921 licentiates; and that, having licensed so large a body of general practitioners of surgery, obstetrics, and medicine, it can no longer afford to "wrap itself up in proud isolation". On this occasion, however, addressing the Fellows of the College, Sir George Burrows especially suggested to that class in the College that their fees might properly be expected to increase in proportion to the general elevation of price in the necessities of life, and higher payment of professional and other services generally. So far as we can read between the lines of the observations of the President of the College of Physicians on the subject of fees, he probably meant to approve of the practice which is now becoming general, by which London physicians commonly charge two guineas instead of one for a first visit, where the case is one requiring some trouble in investigation. He apparently meant to endorse also a two or three guinea fee for visits to distant parts of this great metropolis. From Harley Street to Bow, for instance, or to Wandsworth and back, takes as long a time as to Harrow and back. The practice of half consultations by unpaid letters of medical inquiry is discountenanced by some physicians, but the rule of enclosing a guinea with such letters is not so generally enforced as to make it quite understood by patients to be an accepted custom. It would not have been dignified or prudent for a President of the College to enter into details or to do more than make tentative observations; but the result of what was said will, we conclude, make itself seen in the directions which we indicate.

THE discussion ably and elaborately opened by Dr. Bastian at the Pathological Society on the pathological significance of bacteria was continued on Tuesday evening, and we report it fully. The main element of pathological interest, viz., whether bacteria are to be treated as cause or concomitant, and what is their real pathological meaning, has been a good deal lost sight of. The honours of last Tuesday's debate were with Dr. MacLagan of Dundee and Mr. Hutchinson, neither of whom have discussed categorically, however, the issues which Dr. Bastian had raised. If it be true, as is rumoured, that Sir William Jenner, Dr. Murchison, and Dr. Fayrer may be induced to take part in the debate, it would be a pity that it should be closed before they have been heard. Nor has Dr. Lionel Beale yet been heard, as might have been hoped and expected on such an occasion. Something like a regular inscription of names is desirable in these debates. If the debate should close prematurely, as was shadowed by Mr. De Morgan's suggestion that Dr. Bastian might possibly be asked at once to reply, the debate would be little short of a *fiasco*, and such a result would not be creditable to the Society.

PROFESSOR STOLZ, Dean of the Faculty of Nancy, and Dr. Willemin, Inspecteur des Eaux at Vichy, are at present in London on a tour of inspection of our metropolitan medical establishments. The object in view is, we believe, to obtain certain data with reference to the installation of the medical institutions of that new university which has been transplanted from its former seat at Strasbourg.

THE death of Mr. J. D. Hill reduces the present surgical staff of the Orthopaedic Hospital in Oxford Street, we believe, to one member. Will any one come forward to fill the three vacancies which now exist? They are, it will be remembered, due to the signal ingratitude and discourtesy with which the Committee treated the two senior members of their staff. Hitherto, a striking example of *esprit de corps* has been exhibited by the unanimity with which these vacant appointments have been declined until some reparation has been made. In the public interest, we think, some graceful measure of conciliation by the Committee might now be adopted. It would not be difficult to indicate its proper character.

Nearly two hundred new members of the British Medical Asso-

ciation were again elected last week at the meeting in London of the Committee of Council. This very large number of new members are for the most part either resident in Scotland, or members of the Army and Navy Medical Services.

THE applications for election as members from army and navy medical officers have been very numerous during the last few months. In some cases, they have been forwarded in batches from home and foreign stations; and they are frequently accompanied with the most gratifying expressions of thanks for the valuable aid which the BRITISH MEDICAL JOURNAL and the Parliamentary Bills Committee of the British Medical Association have rendered in elucidating and bringing prominently under notice the grievances of military and naval medical officers, and in promoting their redress. This has for many years been one of the most useful and welcome of our duties; and, in joining the Association so numerous as they have done and are doing, the medical officers of the army and navy unite themselves to a professional body which heartily welcomes them and identifies their interests with its own.

THE Standing Committee of the Conference of Medical Officers of Health for Conjoined Districts has adopted an extensive series of amendments, which it suggests for parliamentary consideration in Committee on the Public Health Bill. The *Sanitary Record* has published a considerable series of suggested amendments from Dr. Bond, Mr. Chambers, Barrister-at-Law, Dr. Ashby, and other authorities. The Parliamentary Bills Committee of the British Medical Association will meet next week to consider these various amendments, and for other business.

A DEPUTATION from the Society for the Prevention of Cruelty to Animals recently inspected the arrangements at Guy's Hospital in connection with the class of Practical Physiology at the Medical School, and, we believe, expressed themselves as gratified and not a little surprised at the humane precautions adopted for the prevention of suffering to any animals which it is necessary to sacrifice for the purpose of medical instruction.

IN connection with the above visit, the story goes that the deputation were introduced to one of the medical officers while engaged in seeing patients. "With this portion of my victims", he observed, "you are not, I believe, interested; we will therefore, if you please, visit the animals."

THERE is a good deal of talk about the extreme silliness of an imposing article in the *Times* on the patent ventilators of a Mr. Tobin. Mr. Tobin's plan of ventilation differs only from other well-known systems, in its omission to provide outlet, and its failure to warm the incoming air, as is done by the corresponding but much better appliances of Captain Galton. The writer of the article seems to think that the application of the pressure of the atmosphere to ventilation, which is at least a hundred years old, is a discovery which makes Mr. Tobin comparable to Columbus. He gives an explanation of the *rationalité* of the apparatus, which suggests that there is no such thing as diffusion of gases, or any necessity for outlet for foul air from an inhabited room. It is a mare's nest of the first water; and the ignorance of the writer is phenomenal, when regard is had to the place and nature of the article, and the grand air of superiority with which the advent of the "Columbus of ventilation" is announced.

WE are sorry that the secretary of the Buxton Hospital has not taken our critical remarks on the clinical appendix to the title of the hospital in good part. They were, however, intended to be useful. The meteorological reports are of unquestioned authenticity, and our compliments on the climate of Buxton are sincere. There are so few places in England that can be complimented on their climate, that this year especially any writer may be pardoned if a touch of irony seemed to follow his pen in writing about early thrushes and precocious buds of spring. Are we ever to have any spring in this sad metropolis?

WHILE the memory of these pleasant revelations of the equable temperature and early spring of Buxton are still fresh with us, we read of a phenomenon in Scotland of which we must frankly avow incredulity. A Scottish correspondent of the *Pall Mall Gazette* announces that the heat in the North of Scotland has been so intense this week, that several cases of sun-stroke have occurred. Sun-stroke in the North of Scotland, while we Southrons are still shivering in the wintry blast, is a malady that requires confirmation. If it be true, we shall all go northward in search of the sun. The heat, however, cannot have been so very intense—not more, it seems, than 85 deg. What ill-advised Scot could manage to get up a sun-stroke at that temperature? Supposing that it be true, we fear the explanation must be that the sun suddenly appeared in a district where its rays have long been unfelt and unseen, and that the astonished inhabitants have suffered from some surprise rather than sun-stroke. However, if there be any sun-stroke to be had just now in the British Islands, there are a good many people who would like to have it.

FLOWERS FOR THE SICK.

A PARAGRAPH in the *Times* a few weeks ago, appealing for presents of flowers for the Home of Industry, Spitalfields, and Mildmay Park, seems to have given some benevolent people the excellent idea of collecting spring and other flowers, and sending them to the hospitals for the patients. We believe a "Flower Mission" has been started with this view, which hails from Commercial Street, Spitalfields. Children are employed in their playtime to gather the flowers in the woods, fields, or gardens, as the case may be, and then the vicar of the parish sends them in hampers to the hospitals. Guy's has been the fortunate recipient of several hampers of flowers during the week, and the Home of Industry has sent one hundred bouquets, in flowerholders, tastefully surrounded by appropriate texts, for the patients. If the clergy will take the matter up warmly, "The Flower Mission" will be the means of cheering many a poor sufferer, and we hope all who have flowers to spare will send them to some one or more of the London hospitals. We assure our readers that a ward at Guy's Hospital, after the arrival of one of these hampers of flowers, was indeed a pleasant and cheering sight. The poor patients seemed to take a new lease of life from the freshness of the flowers, and bright, happy, contented faces were to be seen on all sides after their advent. Will anybody refuse to aid "The Flower Mission", or deny these poor sufferers, so cheaply purchased and yet so inestimably valued, a pleasure as a bunch of fresh, sweet, radiant flowers? We hope some will be sent for the sailors of the hospital at Greenwich.

HYGIENIC EXHIBITION AT BRUSSELS.

AN international exhibition of instruments and apparatus for the preservation of life and health, will be held in Brussels from June to October. The articles exhibited will be arranged in the following classes: 1. Delivery from fire; 2. Apparatus for the prevention of accidents in travelling in streets, tramways, and railways; 3. Apparatus for diminishing danger and affording assistance in regard to water; 4. Aid in war; 5. Hygiene and public cleanliness; 6. Precautionary measures and apparatus for safety in industrial occupations; 7. Hygiene in private life; 8. Medicine, surgery, and pharmacy in their connection with the foregoing classes; 9. Regulations for the improvement of the condition of the working classes; 10. Hygiene and apparatus for preservation of life in their application to husbandry.

THE SUNDERLAND INFIRMARY.

THE Sunderland newspapers have lately contained letters from two patients complaining of their treatment in the infirmary; and subsequently the letters were reproduced as advertisements. A subcommittee was at once appointed by the hospital authorities, and a minute and searching investigation was instituted into the matter. Their report was laid before a general committee, and the evidence proved that the charges were entirely without foundation. The newspaper account leads us to believe that some person in the town, who is hostile to the

taff, had made use of some discontented patients—of whom there will always be some even at the best managed hospital—"to damage the institution or to serve some private motive of malice". But, instead of this, he has only succeeded in rallying the friends of the hospital around it, and bringing more clearly to light the efficient manner in which it is served by its medical officers, and in which the general management is conducted.

OUT-PATIENT HOSPITAL REFORM.

We are glad to hear this most important subject is being investigated at the Westminster Hospital. The different members of the staff are being summoned to give evidence before a subcommittee. We anticipate, with much interest, the conclusions of that committee; as, from the fact of Mr. Hood, F.R.S., and we believe Sir Rutherford Alcock, G.C.B., being upon it, it may be certain the subject will receive the most careful and conscientious treatment.

THE VITAL STATISTICS OF LONDON FOR 1874.

FROM the Annual Summary of the Registrar General for 1874, we gather the following information. The area of London is 78,080 acres, or 122 square miles; upon which resides a population estimated for the middle of the year 1874 at 3,400,701, of whom 1,591,692 were males, and 1,809,009 were females. The population of London resides at a mean elevation of 39 feet above Trinity high-water mark; the elevation varying from 11 feet below high-water mark in Plumstead Marshes, to 429 feet above high-water mark in Hampstead. At the census of 1871 there were within this area 417,767 inhabited houses, containing an average of 7.8 persons to a house. The annual rateable value of property (as assessed in 1871) equalled £19,996,786. In 1871, the density of the population was at the rate of 42 persons to an acre, 26,674 to a square mile. The annual rate of increase of population per cent. from 1851 to 1861 was 1.73; the rate between 1861 and 1871 was 1.50. The births registered in London in 1874 were 121,394; comprising 61,865 males and 59,529 females. Thus the annual rate of births per 1000 persons living was 35.7. The deaths during 1874 were 76,606; the deaths of males were 39,144, and of females 37,462. The annual rate of mortality per 1000 persons living was 22.5; amongst males it was 24.6, amongst females 20.7. The rate from the principal zymotic diseases was 3.3. The increase of the population since the preceding year was 44,544, as estimated by the steady rate of growth in previous years; and the excess of registered births over deaths in 1874 was 44,788, which the Registrar-General denominates a remarkable result. "London is now self-sufficing; it not only sustains its own numbers, but it provides an annual surplus equal to the population of a large city. It was not always so. In the year 1861 the increase of population was 45,000, while the excess of births over deaths was only 32,000. In the year 1851 the increase of population was 44,000, the excess of registered births over deaths was 23,000. In the year 1841 the increase was 36,000, the excess of births over deaths 12,000." In the year 1605, two hundred and sixty-nine years ago, the christenings in London were 6504, the burials 6392. The Registrar-General combats the notion that the Metropolis is a "drain" on the population of the country, or that like a great monster it devours its children. He shows that London can sustain its present increase by native births; and that what actually takes place, is a free influx of people born in the country, and an efflux of people born in London. "The great fact of the increase of children in London, shows the importance of providing adequate means for their education, including schools and playgrounds; for the athletic is only second to the moral training in importance. Now of 100 children born in London, rather more than 72 attain the school age of 3 years; and as 112,617 births were registered in 1871, no less than 81,242 children attained the school age in 1874; while of the 121,394 born in 1874, about 87,574 will attain the school age in 1877. The increase in three years will be some 6332." Increased school-accommodation from year to year will, therefore, be required for some time to come. The returns

of deaths for 1874 were favourable: in fact, "the last three years show a marked reduction in the mortality of London, and imply an improvement of the health of the drained city. The annual mortality for the ten years, 1840-49, was 25.2; for the thirty-five years, 1840-74 it was 24.2; for the last three years, 1872-74, it was 22.2. Upon the population of 1874, this reduction in the mortality of three in 1000 implies a diminution of 10,200 deaths a year." The death-rate in twenty-one large towns of the United Kingdom in 1874 was 25.2. In only one town, Portsmouth, in which it stood at 20.4, was the death-rate lower than it was in London.

THE INVENTOR OF THE LARYNGOSCOPE.

MOST medical men are, we imagine, aware that, although more or less incomplete laryngoscopic examinations had previously been made in this country by the use of mirrors devised by Babington, Liston, Avery, and others, Signor Garcia, the well known professor of singing, was the first who brought laryngoscopy to a practical position, and who practised autolaryngoscopy with the result of publishing at the Royal Society excellent Physiological Observations on the Human Voice, containing a good account of the action of the vocal cord during inspiration and vocalisation. The observations of Garcia led to the further work of Türk and Czermak; and he must probably be considered as in no remote sense the principal author of the modern art of laryngoscopy—an unquestionably valuable resource in modern medicine and surgery. A committee has been formed, of which Lord Coleridge is chairman, and which includes many well-known names in science and art, and among the friends of both, for the purpose of raising a subscription with the object of presenting a testimonial to Signor Garcia, "in special recognition of his claims as the inventor of the laryngoscope, and also as a mark of the high estimation in which he is held by all classes". Mr. George Critchett is the treasurer, and Dr. Morell Mackenzie the honorary secretary, of the fund.

EXECUTION OF AN ABORTIONER.

ALFRED HEAP, who was convicted of the murder of a young woman, at Manchester, by an unsuccessful attempt to procure abortion, was executed at Liverpool on the 19th instant. He had prepared a written confession, which he desired should be published, but it is understood to implicate other persons. He did not deny the offence, but stated that he had no intention of causing death. This execution is one for which there are, we believe, few precedents: it is, nevertheless, one of which the justice is incontestable. It is stated that in other countries the offence is common, and the fatal consequences are usually concealed or slurred over when any public inquiry takes place. When the medical gentleman who undertook part of the inquiry into the practice of baby-farming, conducted for the BRITISH MEDICAL JOURNAL a few years since, called upon one of the women who responded to our advertisement, she avowed the procuring of abortion to be part of her business in life, and showed her favourite implement suspended in the cupboard. It was nothing else than long iron wire. That traffic, as then conducted, was quashed by the revelations which were made in our columns; but the practice still exists apparently, and is carried on secretly by the most degraded and infamous persons. If we may trust what we read and hear of prevalent practices in other countries, the procuring of abortion is not yet there regarded with the detestation, or punished with the severity, which it merits.

TRADE MIXTURES.

REFERRING to the proposed exception in the Government Bill for amending the Adulteration Act, which allows the sale of mixtures which are the subjects of patents, Dr. Cameron, the public analyst for Dublin, says: "A patent has been taken out for converting chicory-root into a form in which it simulates the appearance of coffee-berries; and, consequently, if the Bill become law, such spurious coffee-berries may be legally vended. Another patent has been taken out for the purpose of mixing coffee and chicory, and I am aware that the mixture has been largely sold under the name of patent coffee."

THE FINANCES OF THE ASSOCIATION.

THE balance-sheet of the year has been presented and audited by the public accountants. The financial situation of the Association continues to improve. At the close of the year, every penny due was paid in cash, and there remains a handsome balance, as well as good assets. After paying everything, deducting two hundred and twenty-five pounds for grants, one hundred and fifty pounds for the expenses of incorporation and other legal charges, and writing off several hundred pounds from old arrears, there still remained a respectable profit balance. When it is remembered that the whole operations of the Association are conducted on the basis of a subscription which does not exceed two-thirds of an ordinary subscription to one of our medical contemporaries, the results achieved by that subscription will appear very satisfactory.

THE JACKSONIAN PRIZE.

At a meeting of the Council of the Royal College of Surgeons on the 15th instant, the committee, to whom it was referred, stated that neither of the essays sent in for the Jacksonian Prize exhibited sufficient merit, consequently there was no award. The subject, a thoroughly practical one, was "Tracheotomy, with particular reference to the causes of death after the operation, and the rules for rendering the operation more generally successful". The subject for the present year is "The Use of the Galvano-caustic in the removal of Morbid Growths". In order to prevent the occurrence of a similar mistake to that on the part of one of the competitors last Christmas, in sending in his essay at midnight, we understand that, in future, essays must be delivered before the office of the secretary closes, viz., five o'clock.

CONTAGIOUS DISEASES ACTS.

THE report of Captain Harris, Assistant Police Commissioner, showing the operation of the statute last year, has been presented to Parliament and printed. The number of women who returned to their friends on an intimation as to their conduct was two hundred and fifty-four, and there were two hundred and six other women who were found in bad company, but who were not registered.

NEW BOROUGH FEVER HOSPITAL FOR BIRMINGHAM.

ON the 13th instant, a new Fever Hospital and Convalescent Small-pox Ward, which are now ready for the reception of Birmingham patients, were inspected by the town councillors. These institutions have been erected at Birmingham Heath by the Sanitary Committee of the Town Council. The Fever Hospital consists of two wards, intended for male and female patients, each containing twenty beds; their capacity is sixty feet by twenty-one feet; they are separated by double wooden walls, with sawdust between, and they have gabled slate roofs. At the entrance of each ward are three apartments, a bath-room and lavatory, a room with a stop-sink, and an improved disinfecting earth-closet; all these are, however, cut off from the ward itself by a lobby with cross-ventilation. Each ward has a nurses' room at the opposite end, with a window having a view of the interior of the ward. The walls and ceiling are of varnished pine, which are easily cleaned, and can be quickly disinfected by revarnishing. The Convalescent Small-pox Ward contains twenty-four beds. At present there is no ward for fever convalescents, although the committee could easily convert a room, which is now used for stores, for that purpose if necessary. Including the buildings for nurses, stores, etc., the Birmingham Sanitary Committee possess on this site, belonging to the corporation, no less than ten separate buildings, more or less available for the isolation and treatment of infectious disease, including the Small-pox and Fever Hospitals, and the Convalescent Ward. A solid wall divides these premises from the grounds of the workhouse. Some planting and paving are to be carried out around the hospitals, in order to improve the prospect from the windows of the wards. Every endeavour is being made by the Sanitary Committee to impress upon the public

mind that these hospitals are not pauper institutions, but are intended for all patients who, for the public good and the safety of their own families, can be induced to use them. Upon the successful removal of the prejudice which largely prevails against the use of such institutions, much of the usefulness of those new hospitals for infectious diseases in Birmingham depends.

VIVISECTION.

THE *Athenæum* states what has long been known in the profession, that, in the event of any proposals for legislation with regard to vivisection being brought forward, Mr. Darwin, Professor Huxley, Dr. Sanderson, and other biologists of distinction, intend to petition Parliament on the subject. While they are anxious that any useless cruelty should be prevented, they are extremely desirous that no obstacles should be placed by the action of the legislature on research; and these views will be embodied in the petition. In these views every one will concur, ourselves and this Association most of all.

THE LATE MR. TURNER OF MANCHESTER.

THE executors of the late Mr. Turner, the distinguished surgeon of Manchester, have presented to Owens College his medical and surgical museum, which had been bequeathed to them by the deceased gentleman for the purpose of presentation to some institution in Manchester. The donation will be characterised as "The Turner Collection".

TOTAL ABSTINENCE.

AT the recent annual festival of the Lancashire and Cheshire Band of Hope Union, Sir Henry Thompson, who spoke at length, declared his belief in the principles held by those who formed that gathering. He considered that habitual, or, as it was usually called, moderate drinking, was a thing which people should avoid, if they wished to have a sound mind in a sound body. It is a somewhat remarkable fact, that many of the most hard-worked professional men in London are habitual abstainers from alcohol, and have been so for some years, on the basis of personal experience, and from the fact that they have found the use of alcohol to interfere with their physical health and mental activity.

NORTH LONDON MEDICAL SOCIETY.

A MEETING of medical practitioners was held on Wednesday evening, April 14th, at the Athenæum, Camden Road, to confirm the proceedings of previous meetings held for the purpose of establishing the above Society. The ordinary meetings of this Society will be held at the Athenæum, on the second Wednesday in each month from October to May. It is proposed at these meetings to discuss short papers and records of cases. The following gentlemen were elected officers of the Society: *President*, W. B. Kesteven, Esq.; *Vice-President*, T. S. Dowse, M.D.; *Treasurer*, R. H. Hilliard, M.D.; *Secretary*, W. H. Kesteven, Esq.

DEATH OF MR. EDWIN SERCOMBE.

WE regret to have to announce the death of Mr. Edwin Sercombe, which took place on Wednesday, the 14th inst., at 5 P.M. Eight days prior to this date, Mr. Sercombe caught cold; this was followed by inflammation of the lungs, and in a little more than a week he died. In addition to his usual medical adviser, Sir William Gull was called in, but their skill was unhappily of no avail. Mr. Sercombe occupied a very prominent position in the special branch of surgery which he practised, and held successively the post of committee secretary, and last year that of President, of the Odontological Society of Great Britain. His thoroughness and earnestness of purpose secured to him a large circle of professional and private friends, who will deeply regret his sudden removal from an extended sphere of usefulness in the prime of life.

A VEXATIOUS CHARGE AGAINST A SURGEON.

LAST week, a case was tried at Liverpool, in which a man at Kirkdale brought an action against Mr. E. M. Sheldon, surgeon, to recover £2,000 damages for the loss of his wife, whose death it was

alleged was caused by the negligence of the defendant. The plaintiff's wife was confined on January 16th last, Mr. Sheldon being in attendance. Two days later, an unfavourable change took place, and the patient complained of severe pain in her left side. She was seen from time to time by Mr. Sheldon and his assistant, and also on one occasion by Mr. Edis. But, notwithstanding the measures used by these gentlemen, she gradually sank, and died on the 24th. The woman who was in attendance upon the patient at the time of her delivery was not a "professed" midwife. She was unmarried, and had no experience in such cases. As complaints were made of the manner in which she nursed her patient during the first few days, she was dismissed, and a more experienced person called in. After the witnesses for the prosecution had been examined, his honour said, "I do not think there is any evidence of negligence, and I am prepared to nonsuit the plaintiff". And subsequently he reiterated the same opinion, adding, "The case had the appearance of a somewhat vexatious action, and there was not a shadow of pretence for it". By direction of the Court, a verdict was given for the defendant. Probably, those who are anxious to bring about the regular training and registration of midwives, will see in this case an argument in favour of their views.

RECENT URBAN MORTALITY.

DURING last week, 5,996 births and 3,965 deaths were registered in London and twenty other large towns of the United Kingdom. The annual rate of mortality was 27. It was 24 in Edinburgh, 31 in Glasgow, and 28 in Dublin. The rates in the eighteen English towns, ranged in order, were as follows: Portsmouth, 18; Wolverhampton, 22; Leeds, 24; London, Birmingham, and Nottingham, 25; Sunderland, 26; Liverpool 27; Leicester, Sheffield, Bristol, Salford, and Hull, 28; Newcastle-on-Tyne, 30; Manchester, 31; Bradford, 33; and Oldham and Norwich, 35. The fatality from whooping-cough showed a general decline, but the deaths referred to scarlet fever were again excessive both in Bradford and Hull. In London, 2,591 births and 1,675 deaths were registered; the births exceeded the average by 201, the deaths by 96. The death-rate was 25. To the seven principal zymotic diseases 175 deaths were referred, which were 82 below the average, and equalled a rate of 2.7 per 1,000. The deaths referred to diseases of the respiratory organs were 462, and exceeded the average by 138; 267 resulted from bronchitis, and 130 from pneumonia, including 63 of children under five years of age. In outer London, the general death-rate was 18.2; the zymotic death-rate 1.6, against 25.4 and 2.7 respectively in inner London. The mean reading of the barometer at Greenwich was 30.09 in.; the mean temperature of the air 42.8 deg. or 3.4 deg. below the average. The general direction of the wind was E.N.E. No rain fell during the week.

SCOTLAND.

MR. J. C. EWART, junior demonstrator of anatomy in the University of Edinburgh, has been appointed curator of the University College Museum, London.

AT the meeting of the Edinburgh University Court on the 12th instant, among other business, the court approved of arrangements sanctioned by the Senatus Academicus, under which Dr. Blair Cunyngham is to act for Professor Sanders, as examiner in pathology, along with Dr. Payne, the additional examiner in pathology.

A PERMISSIVE VOTE.

THE town of Rothesay, in the Island of Bute, has come to the conclusion that there are too many public houses within its boundaries, and, in order to test the feeling of the people on the question, a plebiscite has recently been taken. The result is that 1,900 votes have been given for reduction, and 47 against reduction of the number of public-houses in the borough. The papers were signed only by persons who had reached the age of twenty-one years.

THE CHAIR OF MIDWIFERY IN ABERDEEN.

WE hear of several candidates for the chair of midwifery in the University of Aberdeen, vacant by the recent death of Dr. Andrew Inglis. Edinburgh has found three in the persons of Dr. William Stephenson, lecturer on Diseases of Children, and Physician to the Sick Children's Hospital; Dr. A. Milne, Secretary of the Obstetrical Society; and Dr. Coghill, extra-academical lecturer on Pathology; and we understand that two Aberdeen gentlemen are to stand. The chair is in the gift of the Crown.

THE EDINBURGH HARVEIAN SOCIETY.

THE annual festival of the Harveian Society, an institution which has now nearly reached its centenary, was held on the 12th April, Harvey's birthday, and was, as it invariably is, one of the most pleasant and successful of Scottish social medical gatherings. An interesting and able address was read by Dr. Gillespie on Shakespeare, in his relation to medicine and physicians, after which the usual dinner took place, which was attended by a large number of the members of the society. Dr. Omond, in the absence of Dr. Irvine of Pitlochry, the president of the society, occupied the chair; and Dr. Matthews Duncan, the president elect, was croupier.

THE ROYAL INFIRMARY OF EDINBURGH.

A PUBLIC meeting was recently convened by the Provost of Leith, for the purpose of obtaining additional subscriptions from Leith sources for the Royal Infirmary of Edinburgh. Statistics were read to the meeting showing that while the patients admitted from Edinburgh numbered 2,249, those from Leith were 240. The average sum subscribed by Edinburgh for each patient sent was, in 1872, £1 18s.; in 1873, £3; and in 1874 £3, while the amount subscribed from Leith for each patient sent was only £1 1s. 2d. in 1872, £1 4s. in 1873, and £1 8s. in 1874, Leith being thus considerably behind its larger neighbour, with respect to the amount subscribed. A committee was formed to carry out the objects of the meeting.

SCOTCH METHOD OF DEALING WITH QUACKS.

AT the Glasgow Police Court, on the 14th instant, a man named James Perry, carrying on business as a doctor (?) in Buchanan Street, and a bill-poster named Arthur Gilmour, were each fined in the sum of £2 for having distributed obscene leaflets in Trongate. It is to be regretted that some such decided course of action were not adopted more generally on this side of the border.

IRELAND.

ROYAL DUBLIN SOCIETY: THE CHAIR OF CHEMISTRY.

ON Thursday week, Mr. Moss was elected to the Chair of Chemistry, vacant by the promotion of Professor Emerson Reynolds to the University professorship. We are sorry to say the appointment has caused considerable dissatisfaction among scientific men in Dublin. The names of all the candidates were referred to a committee of six scientific men to report upon, select three names, arranging them in the order of merit, and submit them to the Council. Three names were selected, as follows: First, Dr. Bell, a scientific chemist of considerable eminence, and a distinguished graduate of Dublin University; secondly, Mr. Tichbourne, a professional chemist of considerable standing, and for some years the director of the laboratories of the Apothecaries' Hall of Ireland; thirdly, Mr. Moss, a chemist in the employment of Messrs. Bimby and Draper, manufacturing chemists and druggists.

SIR JOHN GRAY, M.D.

THE death of Sir John Gray is an event of considerable importance to the medical profession, especially in Ireland. Although Sir John Gray had not for many years practised in his profession, yet he always took a deep interest in the welfare of his professional brethren, and took an active and intelligent part in all public questions which affected their interests. It will be remembered how active Sir John was as a

medical reformer; and that, at one time, he introduced into Parliament a Bill to amend the Medical Acts; he also took an active part in the Irish sanitary legislation of last year, and accompanied several deputations which waited on the Chief Secretary for Ireland in reference to the Bill. John Gray was the third son of John Gray of Clannorris, in the county of Mayo. He was one of a numerous family, several of whom are well-known in the public services. He was educated at Trinity College, and took the degree of M.D. from the University of Dublin. In 1839, he married Miss Dwyer of Limerick. Dr. Gray settled in practice as a physician some time before his marriage, and continued an active member of the profession until, being attracted by the great political excitement in the days of O'Connell, he became an ardent admirer and constant companion of the "Liberator". Having always been a ready hand at the pen, he became, in 1841, the proprietor of the *Freeman's Journal*, the then, as now, leading journal of the Irish Liberal party. It is a remarkable fact in the history of the *Freeman* that it was established a hundred years previously by the celebrated Dr. Lucas, to which the medical profession of that day owed much. From this time forward, Dr. Gray continued a leading spirit in the troubled sea of Irish politics, taking an active part in the Repeal movement of 1848. Dr. Gray was the chairman of the Water-Works Committee of the Dublin Corporation; and to his great skill, industry, and ability, the services of the great Dublin water-works may be said to be altogether due. For the great services Dr. Gray had rendered the city of Dublin in respect of the water-works, the honour of knighthood was conferred upon him by Lord Carlisle, who was Lord Lieutenant of Ireland at the time when the works were constructed. In 1865, Sir John Gray was elected, without opposition, member for Kilkenny, which city he has since represented without ever being opposed. Although Sir John Gray was more a political than a medical character, yet we cannot refrain from expressing our deep regret at the loss the profession has sustained by the death of one of its few representatives. He was always foremost in the van of sanitary progress, and, although himself a member of the Dublin Corporation, gave great prominence in the columns of his journal to the great question of the sanitary condition of the city, and very recently employed a special commissioner to investigate the causes of the unhealthiness of Dublin. The reports upon this question in the *Freeman's Journal* are likely to be of great value when the sanitary improvement of Dublin is taken up in an earnest spirit by the authorities. We had hoped that Sir John Gray, who had been the leader in the only great sanitary improvement of Dublin, would have lived to see his ideas carried out to their fullest extent by the completion of a system of main drainage, and the general improvement of the habitations of the poor.

BEGGAR'S BUSH BARRACKS.

ON further inquiry, we are glad to learn that these barracks are undergoing a thorough sanitary overhauling, which is calculated to make them more healthy in future. The barracks have been empty for some time; all the drains have been opened, the traps repaired and renewed, and ventilating shafts constructed in every suitable locality. The closets in the officers' quarters have been thoroughly repaired, and the passages leading thereto fitted with permanent ventilators. Careful inquiry leads us to believe that any one of the four persons who died of enteric fever during last year, may have contracted the disease outside the barracks. The buildings must have been in an extremely unsanitary state previous to 1873, and, although improved, must have been in an unsatisfactory state until the improvements now in progress were undertaken.

HEALTH OF DUBLIN: QUARTERLY REPORT.

THE returns for the first quarter of the year show that the births registered amounted to 2,404, and the deaths to 2,700; the mortality being much in excess as regards the corresponding quarters of previous years. The deaths from zymotic diseases numbered 323, or 12 per cent. of the total deaths; 71 deaths resulted from scarlet fever; fever proved fatal

in 77 instances, whilst croup and diarrhoea caused 29 deaths each. To convulsions 149 deaths were ascribed; bronchitis caused 686 deaths; pneumonia, 106; heart-disease, 128; phthisis, 313; hydrocephalus, 44; cancer, 25. Among the deaths, one man and three women were returned as being aged respectively 103, 102, 105, and 107 years.

NEW BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

THE new Thames Valley Branch of the British Medical Association has been recognised by the Committee of Council, and the laws approved. It commences with thirty-eight members—a number which is satisfactory, considering the limited area of the Branch. It will, no doubt, much increase as it becomes known, and if it be actively worked.

THE RUMSEY TESTIMONIAL FUND.

AT a meeting of the Committee held on Tuesday, April 20th, the following subscriptions were announced:—

	£	s.	d.		£	s.	d.
B. St. John Ackers, Esq.	50	0	0	Cheltenham:—			
Sneade Brown, Esq.	25	5	0	J. Walker, Esq.	25	0	0
Cesar H. Hawkins, Esq.				Dr. Kerr	10	10	0
F.R.S.	21	0	0	Dr. Haviland	10	10	0
F. Sibson, Esq., M.D., F.R.S.	10	10	0	Baron de Ferrieres	10	0	0
Sir James Paget, Bart., F.R.S.	10	10	0	Dr. Rooke	5	5	0
J. Simon, Esq., F.R.S.	10	10	0	W. M. Tarett, Esq.	5	0	0
W. Farr, Esq., M.D., F.R.S.	10	10	0	Dr. Williams	5	5	0
Sir W. W. Gull, Bart., M.D., F.R.S.	10	0	0	The Misses Cowell	5	5	0

Subscriptions may be forwarded to Dr. Buchanan, New Government Offices, Whitehall; to the Honorary Secretary; or to Messrs. Roberts, Lubbock, and Co., Bankers, Lombard Street.

Cheques should be made payable to the "Rumsey Testimonial Fund or bearer", and crossed "Roberts, Lubbock, and Co."

Post-office Orders should be drawn on the Curzon Street Post-office, and forwarded to the Honorary Secretary, Dr. W. H. Corfield, 12, Bolton Row, Mayfair, W.

MEMORIAL.—A handsome painted window has just been placed in the south aisle of St. Giles Church, Norwich, to the memory of the late J. Godwin Johnson, F.R.C.S., who died January 13th, 1874. The window is one of three lights, the subjects of which are: "Our Lord healing the lame man"; "Christ blessing little children"; and "The Parable of the Good Samaritan". This window is erected by his old pupils as a token of their love and esteem for him. Mr. Johnson practised for upwards of fifty years in Norwich, where he was universally respected and beloved.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

TUESDAY, APRIL 20TH, 1875.

CAMPBELL DE MORGAN, F.R.C.S., F.R.S., Vice-President, in the Chair.

THE GERM-THEORY OF DISEASE.

THE discussion on Dr. Bastian's paper on the Germ-Theory of disease was continued from the previous meeting.

DR. MACLAGAN (Dundee) : Dr. Bastian has gone over so much ground in the very able paper with which he opened this discussion, that it is impossible for one speaker to deal with more than a part of it. I shall, therefore, confine my remarks, as far as possible, to the germ-theory, in its application to that class of diseases in which the property of contagiousness is most marked—the specific fevers. But, before entering on that subject, I should wish to make a few remarks regarding the general tenour of Dr. Bastian's paper. The first point to which I would refer is, that there crops up through all his essay the idea that supporters of the germ-theory must be panspermists, must be opponents of the doctrines of heterogenesis and archebiosis. As an advocate of the germ-theory, I entirely repudiate this position, and hold myself at liberty to recognise the competence of organisms to produce the phenomena of disease, without being bound down to the belief that they never originate *de novo*. The evolution-theory of life, and the germ-theory of disease, are distinct and separate questions, and neither need have its consideration hampered by the views which we hold regarding the other. The second point to which I would allude is an idea which pervades the whole of Dr. Bastian's paper, the idea, namely, that advocates of the germ-theory regard bacteria as bearing some causal relation to the phenomena of disease. The position is one which Dr. Bastian has created for the germ-theorists rather than they for themselves. I am not aware that any advocate of this theory has distinctly stated that bacteria cause the phenomena of disease. In Dr. Sander-son's report on the intimate pathology of contagion, from which Dr. Bastian quotes, it is said that all microzymes are not contagia, but "all contagia may be microzymes". Observe the "may". The question is only stated hypothetically, and its further elucidation is left for further research. That exactly expresses the position of the advocates of the germ-theory. They could not fail to see that there was a possible connection between the presence of bacteria and the occurrence of diseased processes, but that connection was never declared to be causal. If any advocate of the germ theory ever thought that the connection was causal, he must now give up the idea; for, if the question is to be decided by evidence, we must acknowledge that Dr. Bastian has proved that no such relationship exists. I, for one, freely admit the justice of his claim to have established the position that bacteria are pathological products; but I do not, on that account, abandon the germ-theory. On the contrary, I regard some of the arguments which Dr. Bastian looks upon as fatal to that theory, as really affording to it valuable support. In that part of his paper which deals with violent inflammations and their sequelae, Dr. Bastian advances, "as sufficing to complete the discomfiture of the germ-theory", the fact "that the virulence of certain contagious mixtures diminishes in direct proportion to the increase of bacteria therein"; and when dealing with specific contagious diseases the same argument is repeated: "the virus of most of these contagious diseases, with which definite experiment has been made, is most potent in the fresh state, whilst its power very distinctly diminishes in intensity as organisms reveal their presence more abundantly therein". That is the argument which, Dr. Bastian says, "suffices to complete the discomfiture of the germ theory". Well, sir, I would take the liberty to put a totally different construction on this fact; to claim it as a friend, rather than regard it as a foe; and to look on it as evidence not against, but in favour of, the germ-theory. But what evidence have we of the existence of such protoplasm? I think not a little. According to the view which I take of this theory, the organisms which produce the phenomena of disease are not those which we see and describe as bacteria, but other and much more minute organisms. I think, indeed, it is still an open question, whether true disease-germs have ever been seen. Of their existence we judge by the phenomena to which they give rise, as I shall presently endeavour to show. Now, Dr. Bastian has shown us that the protoplasm of the tissues of epithelial cells and of an amoeba undergoes bacterial degeneration; why may not the protoplasm of contagium-particles of disease-producing organisms do the

same thing? Their composition is similar (albuminous), and they are endowed with no special powers by which, at least in the moist state, they can resist the ordinary tendency of organised material to undergo change. I believe that they do undergo such a change, and that the bacteria which are observed in contagious fluids are formed, in part at least, from the disintegrating elements of the organisms which give to these fluids their specific properties. This is why the virulence of these fluids diminishes in intensity as organisms appear more abundantly therein; and thus it is that Dr. Bastian's main argument against the germ-theory becomes an argument in its favour: the formation of bacteria from previously existing protoplasm being, on Dr. Bastian's own showing, more probable than archebiosis, or their formation from fluid. The germ theory, as I understand it, briefly is, that many diseases result from the propagation in the system of organised particles having no part or share in its normal economy. The question is essentially a pathological one, for the discussion of which the floor of a Pathological Society is a peculiarly fitting place. What we, as pathologists, have to do, is to take the phenomena of disease as they present themselves at the bedside of the patient, and in the *post mortem* room, and see whether the germ-theory is competent to explain the phenomena then and there observed. In this way let us take up the specific fevers. The predominant characteristic common to these is the occurrence of the febrile state, independently of local inflammatory mischief. I do not see how, on any physico-chemical theory, the whole of the individual phenomena which go to constitute the febrile state can be explained. I do see how they can be explained by the germ-theory. It is an acknowledged fact that in all the specific fevers the poison of each is reproduced to an enormous extent during the course of the disease to which it gives rise. Now if this *materies morbi* be, as the advocates of the germ-theory (with the exception of Dr. Beale) maintain, a foreign organism, it is evident that the large consumption of material, which must take place during the rapid formation of millions of such organisms, cannot fail to have a serious effect on the system in which they grow. Be they of animal or of vegetable nature, two things will be largely appropriated during their growth—nitrogen and water. That the propagation in the system of millions of organisms is competent to produce all the phenomena of idopathic fever, I have elsewhere endeavoured to show in some detail, and shall therefore now refer to it very briefly. The primary and essential phenomena of the febrile state are, increased consumption of nitrogen, increased consumption of water, commonly referred to as increased retention, preternatural heat, and increased rapidity of the circulation. The rapid development in the system of an organism, which acts like the tissues in consuming nitrogen and water, will give rise to the same phenomena as would result from a corresponding increase in tissue-formation. Thus it is that the contagium-particles act. They largely consume nitrogen, and thus cause the wasting of the nitrogenous tissues. They largely consume water, and thus cause the thirst, dry skin, scanty urine, and constipated bowels, which characterise the febrile state. It is in the minute structures of the tissues, rather than in the general circulation, that this growth takes place. They are formed in the same way, from the same materials, and at the same time as the tissues; the formation of their protoplasm is, therefore, attended by the same evolution of heat, and the same increased rapidity of the circulation, which would result from a correspondingly increased growth of the protoplasm of the tissues. There is not one of the phenomena of the febrile state which may not thus be explained. But I pass from these, on which time forbids me to enter, to a brief consideration of one or two other characteristics of the specific fevers, viz., those which entitle them to the term specific. First, the phenomena of the febrile state are the common result of the propagation in the system of many different organisms, each of which, always and under all circumstances, gives rise to its own specific disease, and never to any other. From this we infer a specific difference, inherent in the contagium-particles. Secondly, we find that at the end of a definite period, seven, fourteen, or twenty-one days, as the case may be, the fever comes more or less abruptly to an end, while there is still in the system abundance of the material required for the organic growth of the germs. From this we infer that something more than merely nitrogen and water, something more than the bare material requisite for organic growth, is essential to their propagation. Thirdly, we find, as a rule, that the contagia of the specific fevers cannot be propagated more than once in the system. From this we infer that during their propagation something is used up which is not reproduced. Fourthly, we find that in most of the specific fevers there exists some peculiar symptom referable to disturbance or inflammatory action in this or that organ or tissue which imparts to the disease its specific characters, and distinguishes it from all others. Now, putting together these facts (and it is only by facts that theories should be formed), noting that each contagium is possessed of properties

peculiar to itself; finding that something more than the elements essential to organic growth is requisite for the propagation of the contagium; and observing still further that what imparts to each of the specific fevers its distinctive features is not so much any peculiarity of the general symptoms as the existence of local complications of inflammatory mischief in this or that organ or tissue; observing all this, we cannot fail to see that there is probably some connection between this local complication and the specific properties of contagium. What is this connection? It is, I believe, in the organs and tissues whose affection imparts to each form of fever its special characters, and in them only, that the contagium-particles find something which is requisite to their fecundation and propagation as distinguished from their organic growth. For convenience sake, I shall call this something the second factor. For the production of the specific fevers, these two factors are necessary. The first is the contagium; the second that special localised substance or material which is essential to its fecundation and propagation. It is for the recognition of this second factor that I would specially plead. And so with vegetable parasites; each has its own favourite situation, beyond which it is not found. In asking you to recognise its existence, I place before you no vague hypothesis, but a properly welded theory based on a careful study of the facts with which we have to deal. But that is not its sole foundation. To accord to contagia the property of propagating themselves only in certain localities, is simply to endow them with characteristics which are common to all parasites. Nearly every parasite to which man and the lower animals is liable has its own special seat, out of which it cannot propagate itself. This one grows in the small intestine, that in the large; this one in muscle, that in liver; this one in brain, that in kidney. If the germs of any two diseases required the same second factor, the one would protect against the other; thus it is probably that vaccination protects against small-pox. Analogy, therefore, would lead us to accord a similar peculiarity to contagia. Any hesitation that we might have in doing so gives way when we find that, by simply according to them this property which is common to all parasites, we at once get a clue to the explanation of the specific differences of the diseases to which they give rise, and of the peculiarities which each presents. In small-pox this second factor has its seat in the skin; in scarlet fever in the skin and throat; in measles in the skin and mucous surfaces, or the respiratory passages; in typhoid fever in the intestinal glands. So long as any of this second factor remains, the first factor (the contagium) continues to propagate itself; as soon as it is exhausted, the propagation of the contagium ceases, and the febrile symptoms come speedily to an end. If the system into which the germs gain entrance contain little of the second factor, the resulting attack of disease will be slight; if much, it will be severe. If the second factor be widely distributed and readily got at, the disease, as in small-pox, will be very infectious; if confined to narrow limits, and reached with difficulty, as in typhoid fever, it will be slightly so. One word regarding the application of this theory to surgery and the treatment of wounds, with which Mr. Lister's name is associated. In injuries and surgical operations, the wound is the seat of the second factor. Without some solution of continuity, the germs which Mr. Lister seeks to exclude cannot be propagated. By means of antiseptics, says Mr. Lister, destroy any germs which may gain entrance to the wound at the time of its infliction, and by their continued and careful application prevent the entrance of others; and so you may prevent the occurrence of those grave accidents which frequently cause such havoc in surgical wards. That without antiseptic treatment wounds may heal up kindly and quickly, is no very potent argument against Mr. Lister's theory. The explanation of such an objection is the same as that which is given of the fact, that some persons may for a time be exposed to a notoriously infectious disease without contracting it. Mr. Lister does not say that a wound which is not treated antiseptically must go wrong; he only says that it is more likely to do so than one which is so treated, just as the physician does not say that a man who spends some time in a typhus ward must take the disease: he only says he may do so. But the objection has been raised, If Mr. Lister's theory be true and his treatment sound, why are the results not perfect? Even in Mr. Lister's own hands they are not so; and I venture to say they never can be so, for direct contact is not the only way by which the germs may gain access to the wound; there is another mode of communication with it, namely, by the circulation, a means of communication which cannot be occluded. It follows from this that, with the most perfect application of Mr. Lister's treatment, a certain percentage of failure is inevitable—a percentage which might possibly be calculated with some approach to accuracy. The want of absolute success thus becomes an argument not against, but in favour of, Mr. Lister's germ-theory of the origin of the ailments against which he seeks to guard. Did time permit, I would apply this theory to the explanation of the phenomena of many

diseases to which no reference has been made. I hope, however, that I have said enough to show that much may be said in favour of the germ-theory, and that the question may be studied from the pathological side with more advantage than is usually supposed. We judge of the existence of many things only by the effects which they produce. Just as the astronomer would err who refused to recognise the existence and influence of other celestial bodies than those which can be brought within range of his vision by the aid of the telescope, so I believe, though to a less extent, shall we, as pathologists, err if we fail to recognise the existence and influence of other organisms than those which can be seen by the aid of the microscope. Nature teems with organisms, of whose existence before the days of the microscope man had no conception. Who shall dare to say that the limits beyond which organised life is impossible have yet been reached? "There are more things in heaven and in earth than are dreamed of in our philosophy."

Dr. DOUGALL (Glasgow): Allow me, in the first place, to thank you for your courteous invitation to take part in this debate. My own opinions on this subject have been moulded from researches frequently the very opposite of those which formed the opinions of others; that is to say, while others have been more engaged studying the evolution or development and life-history of bacteria and their allies, I have been more employed in eliciting what might be inimical to their development and fatal to their vitality. I have made several thousands of experiments in determining the relative powers of different bodies in preventing the appearance of these organisms in the animal solutions. You have all, doubtless, studied the details of Drs. Bastian and Sanderson's ingenious experiments on this question, and I will give brief details of two of my own. The first is as regards the reaction of the nidus, in which bacteria live. These organisms will only exist in a neutral, faintly alkaline, or faintly acid environment. If an aqueous solution of blood-serum be put in two tubes, and a little acid added to one, so as to make it distinctly acid, it will be found that one soon swarms with bacteria, is turbid and fetid, while the other with the acid is clear, odourless, and contains only torulae, with one or more fungus-tufts, like thistle-down. The bacteria-fluid may not cease to respond to albumen-tests for nearly twelve months, while, *acteris paribus*, the fungus-fluid may cease so to respond in about three months, indicating that the putrefactive and fermentive changes are expended. Now, judging from the negation of the albumen-tests, I submit we have here decomposition of animal matter without bacteria or vibriones. Some may say, "But you have organisms present, torulae and mycelia. If you could show us an animal fluid, decomposing without any kind of organism in it, that would be more satisfactory." Very well; if to an aqueous solution of blood-serum, say of specific gravity 1.6, about one-eighth to one-tenth its bulk of liquor potassae be added, a putrid odour is at once evolved, which soon ceases; and if the mixture be now freely exposed, without previous boiling, at the end of about two months, it gives no response to the tests for albumen. Decomposition has, therefore, been greatly accelerated, and is now completed. Throughout there is a total absence of bacteria, hence of turbidity, and almost no factor. It is well known that alkalis hasten the decomposition of organic matter. Now, in this case, as decomposition proceeds, the fluid is too caustic to allow of bacterial, or, indeed, of any life, while the absence of bad odour is the result of the consentaneous oxidation of the fetid products with their evolution. But it may be said, "If you could show us an animal fluid containing bacteria, and yet not putrefying, that would be proof positive." To this I reply, that bacteria breed rapidly and luxuriantly in solutions of certain salts, ammoniac tartrate, etc., which, of course, are incapable of putrescent decay; thus, I think, completing the proof that putrefaction may exist without bacteria, and bacteria without putrefaction. But if bacteria and their allies do not initiate the conditions associated with their presence, what does? It seems to me the physico-chemical theory interprets all the phenomena, alleged to be explained by the germ-theory, as fully in regard to facts, and more rationally as to hypothesis. If certain liquids, capable of nurturing bacteria, remain barren from the plugged, sealed, contorted, and bent necks of the vessels which contain them, it is obvious that if these contrivances exclude germs of bacteria, they must also exclude dead ferments; and if the mere touching of these liquids with a thread, a hair, a portion of fluid containing bacteria, or a short exposure to the atmosphere, render them fertile, it is manifest that both of what were before excluded are now introduced. Hence it does not follow that the subsequent changes in the fluids are initiated by supposed bacteria-germs any more than by minute particles of effete nitrogenous matter, while the appearance of organisms may be accounted for by archeobiosis and heterogenesis. Of course, it is impossible to isolate germs which cannot be seen with the highest powers of the microscope from merely dead matter; but in two experiments with potash, to which I referred, where the fluid was freely ex-

posed without previous boiling, whatever determined putrefaction, it was certainly not bacteria-germs. It must, then, either have been floating particles of organic debris, or it must have originated spontaneously. The results of some of Dr. Bastian's experiments, however they may take away one's breath, are well worthy of serious study, though there is some difficulty in reconciling them with those of Dr. Sanderson, published in the Thirteenth Medical Report of the Privy Council. As some of these experiments of Dr. Bastian show that putrefaction may originate *de novo* under conditions precluding the possible presence of vitalised supposed bacteria-germs and of dead organic particles in their normal state, it follows that bacteria are as much mere products as are the fetid gases of putrescent change. If the results obtained by Dr. Bastian be applied to the virulent inflammations, such as hospital gangrene, diphtheria, septicæmia, etc., it seems to me that bacteria have no causal connection with them, but are the pathological results of cessation or aberration of the chemical forces exercised by vital tissues. The source and nature of the infectious entities in these diseases is another matter to which I shall again allude. The hypothesis of Dr. Beale, that all the tissues of man and the higher animals are densely interpenetrated by undeveloped and indistinguishable germs of the lowest organisms, seems to me untenable, partly because these germs are indistinguishable, and consequently their existence is only inferred, while it is apparently ably confuted by numerous facts adduced by Drs. Bastian and Sanderson. The views held by my respected teacher Mr. Lister, that bacteria and their allies are the cause of putrefaction, and its sequelæ are, I think, shown to be erroneous by the three and only modes of accounting for the appearance of bacteria stated in the programme of this discussion. The fundamental arguments adduced by Mr. Lister in favour of his theory are, that putrefaction is always accompanied by organisms; that, if these be destroyed by chemical agents, putrefaction ceases; that Pasteur's flask experiments on this point prove that these organisms or their germs are contained in the air; and that if an atmosphere of carbolic acid or some such body be kept around a surgical lesion, and the wound itself impregnated with it, these are rendered inert, and thus putrefaction and its attendant exigencies are averted. Now, it does not seem to me that the arresting or preventing of putrefaction by a chemical body is the effect of its toxic action solely or associated on contiguous organisms (and I may here remark that there are bodies far more fatal to bacteria, etc., than carbolic acid). It is obvious that the soil or pabulum on which they are thriving or would thrive is affected as well. Hence, its decomposition may be arrested or prevented (how is another question), so that the bacteria die not only from being poisoned, but also from being starved. What arrests putrefaction (in decaying matter, of course) prevents it in fresh matter, and *vice versa*. Hence, the action of the arrestant is that of the preventive, and if that of the preventive, it follows that putrescent and putrescible soils are antiseptic independently of any alleged toxic action on concomitant or contiguous organisms. It has also been stated that carbolic acid prevents pyæmia. If it be so, then there is a strong probability that the pyæmic poison is engendered in the tissues, the application of the acid to the lesion preventing its formation. For, as I have repeatedly found that carbolic acid mixed in large proportion with vaccine lymph, also that highly concentrated carbolic vapour, allowed to act on lymph for thirty-six hours, does not annul, and seems to preserve its infective powers, I infer that, if once pyæmic poison be generated, carbolic acid will in like manner not annul, but probably rather preserve, and so disseminate it. A surgeon in a large hospital recently informed me that pyæmia had been very prevalent in the wards of some of his colleagues who use carbolic acid, while in his wards, where no carbolic acid is used, there was no case of the disease. As regards the applicability of the "germ-theory" to typhoid, cholera, small-pox, etc., I think Dr. Richardson gave this theory its quietus about four years ago at the London Medical Society, inasmuch as he said that, if germs be ready to reproduce with the rapidity of reproduction assigned to them, and possess the persistency of life which they are said to possess, it is a wonder that either man or beast are alive, or that the world is not depopulated. The able epitome of existing knowledge of the presence of organisms in contagious and infectious diseases recently published by Dr. Sanderson is unquestionably most valuable, and will undoubtedly prove a permanent contribution to zymotological literature; but I think the presence of these organisms in these diseases may be explained by the physico-chemical-theory. They may be a *de novo* pathological result of a *de novo* disease. It is remarkable that, of the four diseases mentioned by Dr. Sanderson, only one, relapsing fever, is epidemic in the human subject. Dr. Murchison, in his splendid monograph on *Continued Fevers*, has a very able article headed "Spontaneous Generation of Fever," which I advise you to read. He seems to think that this relapsing fever arises *de novo*, and that these organisms are simply the pathological products

of the fever. It does not appear to me that a case, say of small-pox, may always be traced to a previous case, that small-pox does not arise *de novo*, because the conditions under which it originated may have ceased to exist, while those under which it disseminates still prevail. I would apply that reasoning to all other diseases. In conclusion, I believe we shall never cope successfully with communicable diseases till we recognise and practise in their entirety the views that all contagious and infectious viruses have arisen, may arise, and that several of them daily are arising spontaneously, both in and out of the body: in the body, from some unknown perversion of the secretions induced in many ways, but chiefly by prolonged violation of the laws of health: out of the body, from some chemical synthesis, about which we know nothing of the atoms of effete nitrogenous matter, and which, taken into the system, affect the secretions as if the poison had arisen there, or so as to make arise; also that contagia are comparatively easily annihilated by thorough exposure to, and dilution with, atmospheric oxygen, independent of other artificial means, especially acid disinfection, etc. These views account for the apparent persistency of communicable diseases, and for the explosions and quiescence of epidemics, more naturally than by considering zymotic poisons vitalised self-reproductive entities endowed with supernatural powers of resistance to atmospheric and other agencies—powers not possessed, so far as I am aware, by the ova of any motile organism. They also harmonise with Dr. Sanderson's objections to Dr. Beale's views, that disease-germs consist of portions of degraded bioplasm, which, as Dr. Sanderson, I think correctly, observes, "of all perishable things, is the most perishable". But they differ from the views both of Sanderson and Beale in not regarding contagious units as vitalised entities, but simply as fragments of dead organic matter, whose elementary particles are in some occult state of chemical union, and capable of imparting their condition to other bodies susceptible of the same change. I think we have a good example of this process in the propagation of typhoid contagion by milk. Under certain insanitary and morbid states intimately correlated, certain specific viruses are evolved, and for a time the forces of destruction may equal those of evolution; but, should they be less, the accumulated effects culminate in an epidemic till the balance is restored; because people are then up in arms, and sanitation and the forces of destruction for a time preponderate. Far be it from me to undervalue in the least patient and silent research into the remotest regions of the minute pathology of contagion, still I cannot but think that those who refer the complicated phenomenon of specific diseases exclusively to bacteria and their allies, discarding antecedent conditions, of which these organisms are far more likely a harmless effect, will not so soon be gratified at seeing the fruits of their labours in a diminished zymotic mortality as those who hold the opposite opinion.

Dr. CRISP: Rather than the time should be lost, I take the opportunity of rising to say a few words, and I shall confine myself chiefly to the diseases of lower animals. I have often said, at this Society, that students will be obliged to commence with the lower forms of organisation, and work upwards from them. One of the first speakers in this discussion reminded us that we should not imitate the example of the French Academy, but confine ourselves to facts. Now, what are facts? I am an old man now, and I have lived long enough to come to the conclusion that Cullen did a great many years ago, that there are more false facts than false theories; and probably those who hereafter read this discussion will say that it is a confirmation of the statement I have made. I will now confine myself to a few simple facts—for such they really are—as regards the appearance of bacteria in the lower animals. I was the first in this country, some thirty years ago, to direct the attention of the profession to splenic apoplexy. It was never described by any English author; and the cases were all denominated "splenitis" by the veterinary profession. I had a great many opportunities of examining this disease, and I saw many cases of this kind where animals, say thirty or forty oxen, had been turned into a pasture where they quickly got into a plethoric condition, and twenty of them were found dead in one or two days. The same remark applies also to sheep. That is a fact that there can be no question about. I believe that splenic apoplexy might be produced in this way. And what do we find? Generally speaking, the spleen is enlarged and full of blood. I have shown at this Society a portion of an ox-spleen weighing twenty-five or thirty pounds; and in all these cases we found the blood filled with bacteria. So with the whole class of diseases denominated charbon. Davaine, who has not received sufficient attention in connection with this matter, thirty-five years ago began his experiments; and, as I reminded Dr. Sanderson when he brought forward his paper on pyæmia, he appeared to be ignorant of those experiments; he inoculated rabbits with the blood of sheep that had died of this disease, and he went on killing rabbits within a given time, almost to the hour; he inoculated fourteen or fifteen in succession, and they all died within a certain time. In all

those cases, bacteria were found, and without bacteria being present he could not produce these fatal results. In the last volume of our *Transactions*, I have described that disease, which was so fatal to poultry in Ireland. I there found these bacteria. The fowls were in excellent condition, and (as I have known in my own poultry-yard) they died in four hours. Only last week, I had a hen that died in that way. I gave a part of her flesh and intestines to a duck, which died in thirty hours. The blood was filled with bacteria. Then comes the important question—and upon this everything hinges—are these bacteria the cause or the consequence? I confess I am rather disposed to agree with the opinion of the last speaker, that there is some chemical change produced in the blood which occasions these low organisms. We have, I think, no proof, at present, that what is called the germ-theory of disease is founded upon fact. That is the conclusion I have come to; and I think that hereafter it will be found that we must modify our views very much respecting this matter. I might mention other diseases in the lower animals, new diseases that have been introduced during the last few years, such as pleuropneumonia, and the foot-and-mouth disease; but, in my researches, I have not been able to find the same organisms in these diseases that I have found in splenic apoplexy and other allied diseases. I think we might at present argue night after night, and come to no definite or practical conclusion. Such is my impression. But I think the subject is well worthy the investigation especially of young men who are ardent and enthusiastic; and I have no doubt that, before many years, this matter, which is now so mysterious and doubtful, will be definite and pretty certain.

Dr. BURDON SANDERSON: Permit me to say a word in explanation with reference to the statement just made by Dr. Crisp as to M. Davaine's discovery. If I had not properly studied the history of the investigation of splenic apoplexy at the time Dr. Crisp refers to, he certainly has not studied it up to the present moment, for the disease and its relations to new organisms of the particular kind which we have under our consideration, particularly the fact of the existence of organisms in the blood of living animals affected with splenic fever, were referred to by Polander, also by Professor Braun of Dorpat, several years before the first papers of M. Davaine and other French observers made their appearance.

Dr. CRISP: I did not say that Davaine was the discoverer, but that his experiments were of a more practical character. I mentioned this especially, because it is the fashion now to ignore everything that is French, and admire everything that comes from Germany.

Mr. JONATHAN HUTCHINSON: I did not come here to take part in the discussion, because I believe it was the wish of the Society that it should rather be confined to those who have investigated the subject by experiment, and especially by aid of the microscope, and I have no facts of that character to adduce; but, if there be no gentlemen present who desires to speak to that part of the subject, I should like to make a few observations on the general question. And what I should like chiefly to say is this, that I think we are not doing wisely in speaking concerning the contagia of the specialised forms of inflammation at the same time and in the same manner as we speak of the contagia of the specific fevers; and I would submit to the Society whether it would not be better that we should keep these two subjects wholly distinct. I might mention the very able speech of Dr. MacLagan this evening in illustration of my meaning. Dr. MacLagan commenced by saying that he should justify the germ-theory chiefly or solely in reference to the contagia which produce specific fevers. I was extremely interested in the first three-fourths of his speech, which concerned that subject; and I may say that my mind went entirely with his arguments that the specific fevers are specific; that their phenomena and their chemical history prove that they are specific; that they run a definite course, protecting the organism afterwards; that they breed true, which is the test of specificity; that they seem to require that the germs which have produced them in one individual shall be applied; and that they are producible by no other means. And I think that Dr. MacLagan is quite correct in his inference which he wished us to accept, that it is very probable that these diseases arise from something which is very properly termed a germ—a germ in the sense of a seed; just as we might sow a definite crop in the ground, and should know that we could not get the crop unless we sowed the definite seeds. So far as specific fever goes, I quite join in the belief, although founded, *a priori*, on conjecture, with Dr. Sanderson, with Dr. MacLagan, and with those who believe in the germ-theories; but I was disappointed when Dr. MacLagan concluded his speech by seeming to imply that the arguments which support the germ-theory for the specific fevers, support also the germ-theory for the origin of the contagious forms of inflammation; and I suppose that the contagious forms of inflammation are what are meant by "virulent forms of inflammation", in the terms in which the discussion is introduced. I do not know any other way in which "vi-

ruent" can receive a scientific definition. I should be glad if some more carefully defined word had been used, because in surgery and in clinical practice we really do not know how the term "virulent" ought to be applied. I really do not know what Dr. Bastian meant when he used that expression. Now it does seem to me that there are *a priori* reasons for separating the contagious forms of inflammation most definitely, and very widely from specific fevers; and I must repeat what I have said, that I think it is unwise to discuss them in the same manner as if they were at all comparable. My impression would be that the facts which apply to specific fevers do not apply in the least to the contagious forms of inflammation; and I think we shall have to find some other theory to account for the contagiousness—for every one will admit the contagiousness of certain forms of inflammation—quite apart, I repeat, from specific fevers. We have had very ably placed before us the two rival theories, the germ-theory on the one hand, and the physico-chemical theory on the other; the one supported by Dr. Richardson many years ago, and very ably advocated by him since,—applied by him, I believe, not only to the contagious forms of inflammation, but also to the specific fevers. Now, I must say (as, indeed, I have already said), that to my mind the evidence adduced by him, and adduced by the gentleman who has spoken ably this evening in favour of the theory, does not seem to me very satisfactory. I think the germ-theory applies better to the class of facts which we recognise respecting specific fevers, than does any theory on a chemical basis. We should have to suppose something so very special in the chemical products which produces them; and it is less easy, I think, for a man to accept that theory than it is to accept the theory that it is due to something to which the term "germ" is applicable. But if you come to such contagions as that in which gonorrhoea or gonorrhoeal ophthalmia, or erysipelas originates, by which an inflammation not only spreads from one individual to another, but from part to part of the patients' tissues in which it begins, a good instance would be the spreading of erysipelas in a patient's tissues, or the spreading of gonorrhoea along mucous surface affected by it. I say I do not think I am then confined to these two theories. I do not think it is necessary to consider only whether this individual has received some zymotic poison, some vegetable germ which is spreading in the way that yeast grows in fluids, and which is inducing this inflammation from without, or that he has some physico-chemical poison which is causing these results. My impression is, that there is yet another theory which deserves consideration, side by side with these two, and I am not sure that I have heard it alluded to in this discussion. It is this, that the products of inflammation themselves may be the means of contagion; contagion by continuity in the patient's own tissues, contagion through the patient's vascular channels, it may be to somewhat distant parts, or a contagion, if the conditions favour such a transplantation of them, to another individual. Hence I should be inclined to think that a surgeon in the pre-microscopic age who was cognisant of the facts of the spreading of erysipelas, and gonorrhoea, and what we term porrigo of the skin, an important form of skin-disease, in which it appears that the disease is purely local, and spreads by the contagion of the elements produced by the inflammation, I say, I think a surgeon, without the aid of the microscope, and knowing nothing of bacteria, nothing of vegetable germs, would think that he found no satisfactory explanation of the phenomena which were submitted to him in believing that the products of inflammation themselves were the source of contagion, that it was the cells themselves which did it, that the living pus-cells which grew in the patients' tissues caused the inflammatory process to spread in those tissues, and that it was quite competent for these cells, when transferred to another individual, to produce this result, provided they were living; for I do not advocate the doctrine of pus being contagious in the sense in which you would believe, that you might take pus out of an abscess and get contagion. The pus in the abscess would be utterly dead pus, undergoing decomposition, already become fatty, and of which there was no hope that it could again grow. If you wish to illustrate the doctrine of pus-contagion, you must take the pus at the earliest period of its production. It is obvious that I am using the term pus in a rather wide sense as including most of the fatty products of inflammation, and my conjecture would be that these products are themselves the source of contagion. Now, against the idea that there is any contagion derived from without, any germ-contagion which would account for the production of such a disease as gonorrhoea or gonorrhoeal ophthalmia, I submit the fact that we have various degrees of them, varying degrees of severity, and I would illustrate this by referring to the fact that those who are conversant with the practice of inoculating the eye in order to produce artificially gonorrhoeal inflammation of the conjunctivæ—which is sometimes done to cure gonorrhoeal lids—well know that they can produce severe inflammation or slight inflammation of almost any

degree of severity they wish, by selecting the kind of pus which shall act as the contagium. Now, if the inflammation were due to germs, it seems to me that it would be very improbable that these germs should be modified in their character at each stage of inflammation. That germs are derived *ab extra*—a germ in the sense of a pus-cell—I, of course, admit; but I think we ought to draw a strong distinction between a germ which can be got only without the body, and a germ in the sense of a cell—part of the patient's organism, the produce of his tissues. I do not say it is easy to account for the different degrees of severity of gonorrhœal ophthalmia, erysipelas, and phagedæna, which all admittedly vary in degree, and generally in the ratio of the severity of the disease in the patient from whom the contagion is derived. I say it is very difficult to suppose that these are due to specific germs existing without the body, while it is tolerably easy to account for them on the theory I suggest, that they are due to the contagium of living cell-material supplied entirely by inflammatory processes, deranged processes of nutrition, which go by the name of inflammation, in the patient's own tissues. I think that any one who should incline to investigate the theory of pus-contagion, would believe that it is a general law that almost all cell-elements arising in connection with inflammation in the patient's own body are, under favouring conditions, contagious, and that they produce in the recipient a disease of the same type, that is, differing in type, as gonorrhœal inflammation, as erysipelatos inflammation, as porriginous inflammation, as diphtheritic inflammation do in the recipient. I think he would incline also to accept another doctrine, that it is necessary for cells to be produced by a tissue, similar to that in which they are to be transplanted; that gonorrhœal pus, for instance, manifests its potency, as regards contagion, very differently according to the mucous membrane to which it is applied; not all mucous membrane can grow it. The pus produced by the skin appears to grow only on the skin, or, at any rate, it is with great difficulty that it produces any inflammation on a different kind of tissue. I have no doubt that there would be a great number of other circumstances that would regulate and modify the various results which we see in connection with these processes of pus-contagion, such as the age of the patient, the precise character and state of his health, and so forth. But these had in view, I think we should be able fairly to explain most of the phenomena which we meet with in practice, in reference to the contagious forms of inflammation. So much, then, as to the arguments for this doctrine. Then as regards its application in practice, it will be seen, if this theory be correct, we shall fall back from the modern doctrine of the antiseptic treatment of wounds, to the old doctrine of the antiphlogistic treatment; and, it is my strong conviction, that this is what in the end we shall come to, and I do not think that, when a wound secretes pus and inflames, and what you hope are adhesions break down, that is due to any putrefaction of fluids which have been effused. I believe it is due to something which would be much more correctly denominated inflammatory action, and that the decomposition which is undoubtedly a character afterwards, and which is perhaps an important element in keeping up and aggravating the inflammation, a matter which it is very suitable the surgeon should attend to afterwards, is not the primary thing; that it is the inflammation which produces certain products that undergo putrefaction, and not the putrefaction which first sets up the inflammatory action. I believe one might mention a great many facts which would very much favour the view that it is not the introduction of any germs from without which prevents the primary union of wounds, but that it is rather inflammatory action, and that the inflammatory action may originate in very various causes, in mechanical causes, bruised edges of the wound favouring the occurrence of this inflammation, and in other cases, very important indeed in surgical practice, especially in large hospitals, in the contagion of wounds. But then again I refer to my theory, that it is pus-contagion and not the contagion of germs. In proportion to the number of suppurating wounds in any hospital where operations are performed, in proportion to the number of wounds which are suppurating unhealthily, in proportion to the number of wounds which in the least incline towards erysipelatos suppuration, or erysipelatos inflammation, or phagedenic inflammation, will be the disappointment of the surgeon in having good results as regards his operations, because then it is obvious that opportunities for the transference of cells which have originated the inflammation, and which are capable of originating it again in any second recipient, are common about the hospital, getting as they do on the hands of the operator, or his assistants, dressers, spongers, and the like. Hence the presence of what are called hospital diseases. Hence also the explanation of the remarkable success attending the practice of surgeons who are paying special attention to the subject. As soon as a man gets any degree of success, as soon as he diminishes the number of suppurating wounds that he has in his wards,

the old saying applies, "To him that hath, shall be given". It is manifest that the chance of contagion is diminished, and then he gets remarkable success, such as that which attended Mr. Callender at St. Bartholomew's Hospital, Mr. Lister of Edinburgh, and several who have practised ovariectomy, carefully abstaining from the treatment of other cases which would expose their hands to the contagion of purulent secretions. I think some very interesting facts might be got as regards the success of measures adopted on this hypothesis. I believe I have myself had as good results from the systematic adoption of remedies calculated to repress inflammatory action as any that I have read or seen in the hands of those who attempt to prevent putrefaction. I have seen, for instance, and I have no doubt that many surgeons could relate similar cases—a wounded knee-joint healed as satisfactorily, without a trace of inflammation, under the systematic application of ice, blisters over the whole joint, and the use of cold water with a view of repressing inflammation. I would also, in conclusion, explain part of the results which those who use antiseptic remedies have obtained, on the theory that the action of these so-called antiseptics is not at all limited to the prevention of putrefaction. We all know that the preparations of tar, carbolic acid, and creasote, are useful in repressing ordinary cell-growth. Those who have used carbolic acid in application to wounds on the antiseptic theory will be familiar with disappointment on the opposite side. They may prevent the wound from inflaming, it is true; they also prevent it from healing owing to the potency of the carbolic acid preventing cell-growth. My impression is, that the chief success, is due to this; that they do not so much prevent decomposition, which I hold to be unimportant and secondary. It is very important to be attended to, if decomposition have occurred; but not very important as regards endeavouring to prevent it. If you prevent inflammation, if you prevent the accumulation of inflammatory products in the wound, there will be nothing then to decompose. I believe the washing with a solution of carbolic acid, saturating all the cells in the neighbourhood of the wound, is a very efficient means of preventing inflammatory action, and preventing the origin of cells, which would tend to spread inflammation to other parts of the wound, and possibly subsequently be the means of contagion to other patients of the same kind. My main object in speaking is rather to say that it would be wise to discuss without any wish to pre-judge the question these two classes of disease as quite distinct, and that we shall certainly get into error if we confuse the contagious inflammations which are non-specific—more or less special, but certainly not specific in the sense of being always alike—with specific fevers.

MR. KNOWSLEY THORNTON: I should like to make a few remarks in the few minutes which remain, looking at the question in connection with the subject which Mr. Hutchinson has just brought up. I had put down a few observations which I hoped to make in connection with this germ-theory of disease; but I felt considerable difficulty in doing so, because Dr. Bastian's paper seemed to me to have shut out to a great extent the question which I had more particularly studied; namely, the germ theory of fermentation and putrefaction in connection with surgery. It seems to me, as other speakers have said, and as I also understood Mr. Hutchinson to say, that the subjects should be kept more distinctly apart; and we can hardly deal with the question in connection with surgery, so preponderating has been the subject of the germ-theory of disease in the discussion; but Mr. Hutchinson has made some remarks on the antiseptic system to which I should like briefly to refer in connection with the antiphlogistic system. Similar views have lately been brought forward by Professor Billroth, who states his belief that there is a substance of a phlogistic zymoid form in tissues which he seems to think to be the product of inflammation, and that there is also probably a substance formed, a septic zymoid which is the cause of septic diseases such as septicæmia, pyæmia, etc. Then he goes on to say that he thinks there is very likely some close connection between these two substances, or that they may even be identical. There are one or two points which any one who has seen many antiseptic cases must regard as a conclusive argument against such a view. Taking any ordinary wound treated antiseptically from the first with the care that one who has the germ-theory at heart will give it, and taking the precautions that Mr. Lister himself would take to prevent what he believes to be potent causes of putrefaction in the wounds, (and here I think one must speak of germs as distinguished from living organisms, bacteria floating in the atmosphere) when you have this wound so treated, Lister has taught that you may have in the wound, from errors of detail and management, putrid suppuration. You may have also another form of suppuration, inflammation going on even to suppuration, through neglecting certain common surgical precautions, getting tension from serous fluid accumulating in the wound—this tension passing on to inflammation, and the inflammation passing on to suppuration, and still this suppuration is not putrid. You may have again another form of

inflammation passing on to suppuration from the direct action of the antiseptic substance you use. As, for instance, if carbolic acid dressings are too strong next the wound, they will first inflame the wound, and then that inflammation will pass on to suppuration; but in neither of these cases does one find any bacteria or any putridity. Putting the two things together it seems to me, if we look at the question from this view, that it is destructive to Billroth's idea of these two substances being identical, because if we have such a condition as this—a condition of tensile suppuration in a wound treated antiseptically, and the matter so accumulated is let out by incision, and care taken that it is all let out; that it shall have free escape—that any oozing that takes place afterwards, or any fresh matter that is formed shall have free escape, we shall have no further accumulation; it just acts as an abscess acts under antiseptic treatment. If you let out the pus, if the antiseptic treatment be perfect, you will have no more pus, you will have serum, but not pus. In the same way when the wound is treated antiseptically the inflammation stops at once when the cause is removed. Now, if there be a substance like this which Professor Billroth imagines is formed in the wound, I think we might expect, at any rate to some extent, continuous action, and that suppuration would not stop abruptly when the outward cause was removed. So, in the same way, it would apply to antiseptic suppuration. Then with regard to the septic zymoid, if the septic zymoid and the phlogistic zymoid were identical, after you have once had the tissue put into a position to form this phlogistic zymoid by the tension, or by the irritation of the antiseptic, then the suppuration would pass on to septic suppuration; but we know that that does not take place. I understand from Mr. Hutchinson that his is a very similar view as to the formation of some such substance in the wounds. Another thing that he has mentioned is the subject of the treatment of ovarian cases. That is a subject in which I have also taken great interest, and it has been constantly thrown in my teeth as a believer in antiseptics. How do you explain the circumstance of ovarian cases doing so well? Surely, there you give the germs every chance; you have a large surface exposed; you have extensive adhesions to deal with; and if the germs be floating in the atmosphere, surely they have every chance of causing putrefaction. Certainly, I for one have seen most rapid and fatal cases of septicaemia in connection with ovariectomy, but happily they are rare. When we do get a case of septicaemia, I think, most surgeons who have practised ovariectomy will bear me out, it is often rapidly fatal. It seems to me that the reason why we have not more of it, and why ovarian cases do so well, is this, that immediately after you have done your operation you free the tissues from all sources of outward irritation, you thoroughly protect them, and leave them as nearly as possible as in the case of a wound in a state of health; the parts are left in a state of absolute perfect rest. There is nothing to interfere with them; there is no tension; the parts are all lax; there is nothing to interfere with the healthy processes going on; therefore, that idea which Professor Billroth seems to hold strongly, that there is vitality in the tissues in health which resists the action of these germs, and prevents the development of bacteria, will explain this—we have the tissues as nearly as possible in a state of health, and therefore, in an ordinary way the germs do not develop. If, on the other hand, we get a case where the patient is in bad health, the tissues have not the vitality required, and there we get these rapidly fatal cases. I hope that in making these remarks I have not strayed from the path which the discussion should have taken. As Mr. Hutchinson brought up the subject, I thought I might be allowed to refer to it.

The further discussion of the subject was adjourned.

DIAGNOSIS OF BLOOD-CORPUSCLES.—Dr. Woodward, in the *American Journal of the Medical Sciences* for January 1875, comes to the conclusion that, if the microscopist, summoned as a scientific expert to examine a suspected blood-stain, should succeed in soaking out the corpuscles in such a way as to enable him to recognise them to be circular discs, and to measure them, and should he then find their diameter comes within the limits possible for human blood, his duty, in the present state of our knowledge, is clear. He must, of course, in his evidence, present the facts as actually observed; but he has no right to conclude his testimony without making it clearly understood, by both judge and jury, that blood from the dog and several other animals would give stains possessing the same properties, and that neither by the microscope, nor by any other means yet known to science, can the expert determine that a given stain is composed of human blood, and could not have been derived from any other source.

DEPUTY SURGEON-GENERAL C. R. FRANCIS, M.B., of the Indian Medical Department, has retired on an allowance of £456 per annum, together with an additional pension of £250.

ASSOCIATION INTELLIGENCE.

REPORT OF MEETING OF COMMITTEE OF COUNCIL.

At a meeting of the Committee of Council held at the offices of the Association, 36, Great Queen Street, London, on Thursday the 15th day of April, 1875.—Present, Mr. G. Southam, President of the Council, in the chair; Dr. Falconer (Treasurer); Mr. Alfred Baker; Mr. E. C. Board; Dr. J. M. Bryan; Sir J. Cordy Burrows; Mr. Callender, F.R.S.; Dr. Alfred Carpenter; Dr. Ward Cousins; Dr. Farquharson; Dr. B. Foster; Dr. E. L. Fox; Mr. Berkeley Hill; Mr. J. R. Humphreys; Mr. W. D. Husband; Mr. F. E. Manby; Mr. R. H. B. Nicholson; Dr. C. Parsons; Dr. R. Quain, F.R.S.; Dr. Shettle; Mr. T. Heckstall Smith; Dr. T. Underhill; Dr. Waters, Chester; Mr. C. G. Wheelhouse; Dr. E. Wilkinson.

The minutes of last meeting were read and confirmed.

Read letters of apology for non-attendance from Dr. Steele and Dr. Wade; an apology was also received from Dr. Sibson, F.R.S.

Resolved—That the 193 gentlemen whose names appear on the circular convening the meeting, be, and they are hereby, elected members of the British Medical Association.

Resolved—That the minutes of the JOURNAL and Finance Committee of this day's date be approved, and the recommendations carried into effect.

Read letter from Mr. W. Fairlie Clarke, and memorial on the abuse of hospitals.

Resolved—That the memorial be presented at the annual meeting, with the suggestion that a committee should be appointed to consider the whole question of medical relief by the hospitals and dispensaries of the United Kingdom, and to report thereon.

Resolved—That the gentlemen forwarding the memorial relative to the mismanagement of medical charities be requested to devise some measure of reform, to be considered at the next general meeting of the Association.

A statement by those gentlemen appointed to consider the report of the State Medicine Qualification Committee, and advise the Committee of Council upon the matter, was read by Mr. Wheelhouse, of which the following is a copy,

Your Subcommittee are of opinion (a) with reference to (i) Poor-law medical officers:

1. That it is desirable that every person holding any public appointment connected with medical attendance upon the poor should have a fair knowledge of the principles of Public Hygiene.

2. It is also desirable that every medical man should be competent (as proved by examination) to fill such offices, and that every candidate for admission into the medical profession should, therefore, have a fair knowledge of the principles of Public Hygiene.

3. That it is desirable that every person holding the office of medical officer of health shall have passed through the ordinary curriculum of medical education, and shall be possessed of such medical qualification as shall entitle him to registration in the *Medical Register*.

4. That it is desirable that every corporation duly entitled to grant such qualifications as shall confer the legal right to registration in the *Medical Register*, shall be further entitled to grant a special qualification in State Medicine also.

5. That this qualification shall include an adequate knowledge both of *Legal Medicine*, or *Medical Jurisprudence*, and of *Preventive Medicine*, or *Public Hygiene*, comprehending *Medical Police* and the management of Medical Institutions supported by national or local taxation.

6. That every one holding this qualification be entitled to register it as an additional qualification (see Medical Act, 1858).

7. That the General Medical Council be empowered and required to prepare a scheme for the examination in State Medicine to be carried out by all Licensing Bodies. The scheme to specify: (a) The number, qualifications, duration in office, duties, and remuneration, of the examiners; (b) The subjects of examination; (c) The nature and methods of examination; (d) The forms of special diploma or special certificate to be granted by any Board of qualified examiners; (e) The fees to be paid, if any, by candidates for examination; (f) The places and times for holding the examination.

8. That each Licensing Body be empowered to grant the diploma in State Medicine to qualified medical men now holding office of a certain standing, and to medical officers of the Army and Navy, after a practical and oral examination.

9. That until January 1st, 1880, matters be permitted to remain *in statu quo*; and that after January 1st, 1880, no medical officer duly appointed before that time shall be disturbed in his office or appointment in consequence of not holding such special diploma or certificate.

10. That, after a given time—say the first day of January, 1880—no candidate for any appointment as medical officer of health shall be eligible for election unless he is able to produce a special diploma of having passed an examination in State Medicine by some one of the recognised authorities, in addition to his diploma entitling him to practise medicine generally, and to be enrolled in the *Medical Register*.

Resolved—That the report be approved, adopted, and entered on the minutes.

Read letter from Dr. Langdon Down, enclosing copy of laws, and reporting the formation, of the Thames Valley Branch.

Resolved—That the proposed laws of the Thames Valley Branch be approved, and the Branch recognised.

Resolved—That the thanks of the Committee of Council be given to Dr. Langdon Down and others for their exertions in promoting the new Branch, and congratulations that they have proved so successful.

Resolved—That the financial statement for 1874 be received, approved, and published in the JOURNAL.

Read resolution of Gloucestershire Branch respecting Dr. Rumsey.

Resolved—That the President of the Committee of Council, the Treasurer, and Dr. Carpenter, be requested to draw up a memorial on behalf of the British Medical Association to the Premier in favour of Dr. Rumsey; and that it be the specific object of the memorial to ask from the Government a pension for Dr. Rumsey, in recognition of his services to State Medicine.

FINANCIAL STATEMENT FOR THE YEAR ENDING DECEMBER 31ST, 1874.

Summary of Receipts and Payments for the Twelve Months ending December 31st, 1874.

Dr.]	RECEIPTS.	£	s.	d.	£	s.	d.

We have examined the above accounts for the year 1874, with the books and vouchers of the Association, and find the same to be correct.

PRICE, WATERHOUSE, & Co., 13, Gresham Street, E.C.

April 8th, 1875.

R. W. FALCONER, M.D., Treasurer.

April 15th, 1875.

MIDLAND BRANCH.

A QUARTERLY meeting will be held at Lincoln on Wednesday, May 5th. Members desirous of reading papers are requested to communicate at once with

C. HARRISON, M.D., Hon. Sec.

Lincoln, April 11th, 1875.

NORTH OF ENGLAND BRANCH.

THE Spring Meeting of the above Branch will be held at the Assembly Rooms, Bath Terrace, Tynemouth, on Thursday, April 29th, at two P.M. The following papers have been promised :

1. On the Treatment of Habitual Drunkards. By Dr. Eastwood.
2. On the Pathology of Catarrhal Pneumonia. By Dr. Macdonald.
3. A case of Extrauterine Foetation. By Dr. Byrom Bramwell.
4. A case of Extrauterine Foetation. By Thomas Wilson, Esq.
5. A case of supposed Renal Calculus. By Anthony Bell, Esq.

Gentlemen who are desirous of reading papers, exhibiting pathological specimens, or making other communications, are requested to communicate with the secretary, at their earliest convenience. Dinner at the Bath Hotel, Tynemouth, at four P.M. Tickets, 7s. 6d., exclusive of wine.

G. H. PHILLIPSON, M.D., *Honorary Secretary.*

Newcastle-upon-Tyne, April 3rd, 1875.

BORDER COUNTIES BRANCH.

THE spring meeting of the Branch will be held at Carlisle on May 12th, 1875. President, Dr. Green, Kendal; President-elect, Dr. W. A. F. Browne, Dumfries. Gentlemen intending to read papers, or be present at the dinner, are requested to give notice to the Secretaries.

HENRY BARNES, M.D. } *Hon.*

Carlisle, April 13th, 1875. J. SMITH, M.D. } *Sec.*

MIDLAND BRANCH.

A QUARTERLY MEETING will be held in the Board Room of the County Hospital at Lincoln, on Wednesday, May 5th, at two P.M.

Notice has been received of the following communications :

Ether as an Anæsthetic, and Notes of Cases. By C. Bell Taylor, M.D.
A case of Scald of Glottis, with recovery after the operation of tracheotomy. By the President.

A meeting of the Council of the Branch will be held at 12.30 on the same day, at the house of the President in James Street.

Lincoln, April 19th, 1875. C. HARRISON, M.D., *Hon. Sec.*

BATH AND BRISTOL BRANCH.

TUE sixth ordinary meeting of this Branch will be held at the York House, Bath, on Thursday evening, May 13th at 7.15 P.M. F. Mason, Esq., President.

R. S. FOWLER } *Hon.*

Bath, April 1875. E. C. BOARD } *Sec.*

CORRESPONDENCE.

MR. SPENCER WELLS'S ADDRESS ON PUERPERAL FEVER.

STR,—In your report of my Address on Puerperal Fever at the Obstetrical Society, a quotation from an address delivered twelve years ago at the Cambridge meeting of our Association has been accidentally omitted. The paragraph is in the second column of page 502 of your present volume ; and I shall be obliged if you will have the following passage published this week. It is a correct report of what I said, and appears to be essential to the coherence of the argument.

Now that the influence of bacteria is beginning to assume a more general importance in pathological investigation, I must ask you to listen to the following account, published, I must remind you, twelve years ago, of what I even then thought Pasteur's discoveries were leading us to.

"Carrying on the analogy between puerperal fever and purulent infection in the various forms which contribute so large a share to the excessive mortality after surgical operations, and applying the knowledge for which we are indebted to Pasteur of the presence in the atmosphere of organic germs which will grow, develop, and multiply, under favourable conditions, it is easy to understand that some germs find their most appropriate nutriment in the secretions from wounds, or in pus, and that they so modify it as to convert it into a poison when absorbed ; or that the germs after development, multiplication, and death may form a putrid infecting matter ; or that they may enter the blood and develop themselves, effecting in the process deadly changes in the circulating fluid. That these low forms of animal life may seriously affect the blood of the higher orders of animals is clearly proved by the recent researches of Davaine, who has furnished us with the first well established example of a disease of the blood due to the presence of inferior beings which are capable of development and multiplication in the torrent of the circulation. These creatures (bacteria) differ from

the whole class of infusoria which form in putrefied matter, as they disappear completely as soon as putrefaction of the blood commences. The bacteria are rapid consumers of oxygen, and when they exist in the blood they absorb the greater portion of the oxygen furnished by respiration, and thus hinder the combustion of all the effete and used-up substances which ought to be eliminated from the body."

The remainder of the address is reported with perfect accuracy.

I am, sir, yours, etc., T. SPENCER WELLS.

3, Upper Grosvenor Square, April 20th, 1875.

* * The paragraph which Mr. Wells sends, commencing "Now that," should be substituted for the first sentence of the first paragraph on page 502, column 2.

PUERPERAL INFECTION.

STR,—I was very pleased to read the paper of Mr. Henry Hatherley, in the JOURNAL of April 17th, on Midwifery Practice and Infectious Diseases. It recalls one I had some years ago. A woman who had been confined a week sent for me. I found her suffering from a sharp attack of scarlet fever in the desquamative stage ; she recovered in a short time without a single unfavourable symptom. I cannot but think, with Mr. Hatherley, that the danger of infection is overrated. I know many country practitioners who have scarcely ever had a case of puerperal fever, but who are constantly attending patients suffering from all sorts of fevers and lying-in women at the same time. I attended a lady two months ago in her confinement ; she had a sharp attack of puerperal peritonitis afterwards. The day I attended her, I had seen one case of typhoid, but had washed my hands and changed my coat before going to her. Since then, I sent her to London to see an ophthalmic surgeon of much repute about her eyes. He told her distinctly that my having attended the case of typhoid while attending her was the cause of her illness ; and that every medical man attending any sort of fever ought to have a friend to take his midwifery. How a man in the country is to do that, I cannot see, as we country practitioners have always infectious cases and must attend them.—I am, sir, yours, etc.,

H. M. L.

THE CONTAGIOUS DISEASES ACTS.

STR,—I agree with Dr. Nevins that the statistics of venereal disease in the Royal Engineers have been sufficiently discussed, and that the profession can form its judgment without further correspondence.

There is, however, one sentence in Dr. Nevins's letter to you last week which requires a word of reply. He says he has called upon the advocates of the Acts to refer to Dr. Balfour's returns "instead of their own picked and unauthentic statistics". This curious imputation, that we have not referred to Dr. Balfour's returns, is also stated in a paper called the *Medical Enquirer*, which is published at Liverpool avowedly in support of Dr. Nevins and the other opponents of the Acts. This paper says : "Neglecting the published Army and Navy Returns which are open to everyone's inspection, and which have, moreover, the advantage of referring to very large bodies of men, Dr. Parkes, Mr. Myers, and others prefer to select individual regiments, or parts of regiments, the facts and figures regarding which are known to none but the selves or their informants." The contention, nevertheless, of the advocates of the Acts has always been that the Army and Navy Returns are quite sufficient to prove the beneficial effect of the Acts. So far from neglecting these Army Returns, I may refer to my first letter, published in your JOURNAL on December 19th, 1874, and to the exhaustive analyses of these Returns, published by Dr. Lawson in a contemporary on December 20th, 1874, and repeated and enlarged in your last week's issue, as showing how thoroughly they have been used.

The evidence subsequently furnished by various medical officers is most valuable, and is supplementary and not contradictory to the official statistics. The figures furnished by these officers are perfectly "authentic". They are taken from the Regimental Returns which are transmitted to head quarters, and form the basis of the tables there calculated. Dr. Nevins has no more right to doubt the accuracy of the figures given by Surgeons-Major Fox, Gore, Ffolliott, and others, than he would have to doubt the figures of any hospital physician of London or Liverpool who laid the statistics of a disease before the profession.

The tactics of the opponents of the Acts are so sluffy that it would take a long letter to expose all their errors ; but I have thought it necessary to assert the good faith and accuracy of the army medical officers who have engaged in this controversy against Dr. Nevins's unfounded assertion that their figures are "unauthentic".—I am, etc.,

Netley, April 18th, 1875.

E. A. PARKES.

MEDICAL OFFICERS OF HOSPITALS.

STR,—I am anxious to correct an error in one of your leaders in the

JOURNAL of last week. You there state that "in Chester, Shrewsbury, Norwich, and Taunton, where the rules in each case require three physicians, *but allow general practitioners to hold the office, etc.*" Now, the fact is, that in Norwich none of the physicians are general practitioners, none of them dispense medicine or perform surgical operations; neither do I think during the more than one hundred years the Norfolk and Norwich Hospital has been established, any gentleman has been appointed physician to it being at the time in general practice. It is quite true that all the present physicians and several before them were general practitioners earlier in their career, but none of them continued to be so after their appointment, nor would they otherwise have been appointed to the office of physician. Please correct the mistake, and believe me, yours truly,

E. COPEMAN, M.D.,

Senior Physician to the Norfolk and Norwich Hospital.

Norwich, April 15th, 1875.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Thursday, April 15th.

Supply of Water to Rural Districts.—Mr. SCLATER-BOOTH, in reply to Sir G. Jenkinson, said the Government did not contemplate any further measures for the supply of water to rural villages and districts than those contained in the Public Health Bill.

The Artisans' Dwellings Bill passed through committee.

The Public Health Bill was read a second time after a short debate, in the course of which Dr. PLAYFAIR keenly criticised some of the provisions, and was replied to by Mr. SCLATER-BOOTH on behalf of the Government.

Sale of Food and Drugs Bill.—Progress was made with this Bill in committee.

Monday, April 19th.

Notices.—Dr. LYON PLAYFAIR has given notice that he intends to ask the President of the Local Government Board whether, in continuation of the reports (134) of the non-medical inspectors of the Board, on their proceedings in bringing into operation the machinery of the Public Health Act of 1872, it is the intention of the Government to lay before Parliament reports, by the medical officer of the Board on the practical efficiency of the Act in promoting public health.—Mr. JAMES has given notice of his intention to ask for return of laws and regulations in France, Prussia, Belgium, Holland, Russia, Sweden, Austria, and the United States, relating to the registration and supervision of midwives.

MEDICAL NEWS.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 15th, 1875.

Bevan, Richard, Clyde Terrace, New Cross.
Howard, Edwin, Lansdown Place, Wandsworth Road.
Lucas, Arthur, Burwell, Cambridgeshire.
Parker, William Herbert, Cheltenham.
Phelps, William, Weston-Super-Mare.
Rodwell, Edward Manly, Loddon, Norwich.
Thompson, Thomas William, Tavistock Square.

The following gentleman also on the same day passed his primary professional examination.

Harrar, James Raffles, General Hospital, Birmingham.

MEDICAL VACANCIES.

THE following vacancies are announced:—

ABINGDON UNION.—Medical Officer for the Workhouse. Salary, £45 per annum.—Medical Officer for No. 2 District. Salary, £115 per annum. Applications on or before the 24th instant.

ARDWICK AND ANCOATS DISPENSARY.—Junior Resident House-Surgeon. Salary, £100 per annum. Applications on or before the 25th instant.

BETHLEM HOSPITAL.—Two Resident Medical Students.

BRADFORD INFIRMARY AND DISPENSARY.—Physician. Applications to be sent on or before June 12th.

BROADMOOR CRIMINAL LUNATIC ASYLUM.—Assistant Medical Officer. Salary, £200 per annum, with furnished apartments, coals, gas, and attendance.

CHELTEHAM GENERAL HOSPITAL AND DISPENSARY.—Junior House Surgeon. Salary, £80 per annum, with board and residence.

DOVER UNION.—Medical Officer for the St. Mary's District and the Workhouse. Salary, £180 per annum.

GRAVESEND AND MILTON UNION.—Medical Officer for the Milton District. Salary, £70.

GREAT YARMOUTH HOSPITAL.—House-Surgeon. Salary, £100 per annum, with furnished apartments, coals, gas, and attendance. Applications on or before May 12th.

HOUGHTON-LE-SPRING UNION.—Medical Officer for the Rainton District. Salary, £25 per annum.

HULL BOROUGH ASYLUM.—Resident Medical Superintendent. Salary, £350, with coals, gas, washing, and vegetables. Applications on or before the 24th instant.

KENT AND CANTERBURY HOSPITAL.—Assistant House-Surgeon and Dispenser. Salary, £50 per annum, with board, lodging, and washing. Applications on or before the 30th instant.

KILCHREHAN AND DALARICH. Parish of—Salary, £80 per annum. Applications, on or before May 1st, to the Chairman of the Local Board.

LIVERPOOL DISPENSARIES.—Assistant Resident House-Surgeon. Salary, £108 per annum, with furnished apartments, coals, gas, and attendance. Applications on or before the 28th instant.

LUTON UNION.—Medical Officer for the Workhouse. Salary, £30 per annum.
MANORHAMILTON UNION. Dromahaire Dispensary District.—Medical Officer. Salary, £100 and fees, with £15 as Sanitary Officer. Applications on or before the 27th instant.

MILFORD UNION, co. Donegal.—Medical Officer for the Ramelton Dispensary District. Salary, £100 per annum, and fees.

NEWMARKET UNION.—Medical Officer for Nos. 1 and 3 Districts. Salary, £85 per annum.

NEWBURY UNION.—Medical Officer for the Second District. Salary, £140 per annum. Medical Officer for the Fifth District.

OLDCASTLE UNION. Crossahel Dispensary District.—Medical Officer. Salary, £100 and fees, with £15 as Sanitary Officer. Applications on or before May 4th.

PADDINGTON, Vestry of.—Medical Officer of Health. Salary, £300 per annum. Applications on or before May 4th.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.—House-Surgeon.

ROYAL INFIRMARY FOR WOMEN AND CHILDREN, Waterloo Bridge Road.—Physician.

ROYAL LONDON OPHTHALMIC HOSPITAL.—Clinical Assistants and Ophthalmic Dressers. Applications on or before the 27th instant.

ST. GEORGE'S (Hanover Square) DISPENSARY.—Physician. Applications on or before May 8th.

ST. GEORGE'S AND ST. JAMES'S DISPENSARY.—Accoucheur and Surgeon. Applications on the 20th instant.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.

SPALDING UNION.—Medical Officer for the Gosberton District. Salary, £40 per annum.

STOUBRIDGE RURAL AND URBAN SANITARY DISTRICT.—Medical Officer of Health.—Salary, £50 per annum. Applications on or before the 24th instant.

TORBAY INFIRMARY.—House-Surgeon. Salary, £100 per annum, with board and lodging.

TORONTO ASYLUM, Canada.—Medical Superintendent. Salary, £411 per annum, with furnished apartments, fuel, light, and furnished table for family. Applications on or before May 15th.

TOTNES UNION.—Medical Officer for the Ninth District. Salary, £20 per annum.

WANGFORD UNION.—Medical Officer for the Bungay District. Salary, £90 per annum.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House-Surgeon. Salary, £100 per annum, with board, washing, and furnished apartments. Applications on or before May 3rd.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

DAVIES, F. Pritchard, M.B. and C.M.Ed., M.R.C.S.Eng., Assistant Medical Officer, State Lunatic Asylum, Broadmoor, appointed Senior Assistant Medical Officer to the Kent County Asylum, Barming Heath, near Maidstone.

EAGAR, Robert T. H., M.B., appointed House-Surgeon to the Coventry and Warwickshire Hospital, vice R. B. Wybrants, L.K.Q.C.P.I., resigned.

LAING, JAMES, M.B., appointed Medical Officer for Out-patients to St. Mary's Hospital for Women and Children, Manchester.

RICHARDSON, Charles S., L.K.Q.C.P.I., appointed a Medical Officer for Out-patients to St. Mary's Hospital for Women and Children, Manchester.

SHAPPEL, Lewis, M.B., appointed Consulting Physician to the Wonsford House Lunatic Asylum, Exeter.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

MARRIAGE.

LEWIS-JOHNSTON.—On April 14th, at Crumlin Church, county Antrim, by the Rev. Robert Campbell, Templepatrick, assisted by the Rev. Robert Cleland, B.A., Crumlin, William Lewis, M.D., C.M., L.R.C.P.Ed., L.R.C.S.Ed., etc., of Houston, Renfrewshire, to Annie, daughter of William Johnston, Esq., of Mountain Lodge and Clady, county Antrim.

DEATHS.

ATKINSON.—At Pontefract, on April 13th, Margaret, the beloved wife of George Paul Atkinson, Surgeon.

SERCOMBE.—Died on April 14th, in the 40th year of his age, at his private residence, 59, Gloucester Gardens, Hyde Park, Edwin Sercombe, M.R.C.S., also of 41, Brook Street, Grosvenor Square, fourth son of the late J. C. Sercombe, Esq., J.P., of Colletan Crescent, Exeter. Interment at Bournemouth on the 22nd inst. Friends will please accept this intimation.

PRESENTATION.—On the 10th instant, the students, past and present, of the City of Dublin Hospital presented Mr. Wheeler, one of the surgeons of the institution, with an illuminated address, accompanied by a clock, inlaid with malachite and gold, a pocket case of instruments and two bronze figures, as an expression of their grateful feeling for the instruction received from him whilst attending the hospital. After the presentation, those present were entertained at supper by Mr. Wheeler.

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London, 8 P.M. Mr. William Adams, "On the Treatment of Broken Nose by Forceful Straightening and Mechanical Means"; Mr. Henry Smith, "On the Results afforded by four hundred cases of Hemorrhoids and Prolapsus of the Rectum operated on by the Clamp and Caustery".

TUESDAY.—Royal Medical and Chirurgical Society, 8.30 P.M. Dr. W. H. Day, "On Pulmonary and Cardiac Complications of Abdominal Tumours"; Mr. Fergusson McGill, "Case of Left Subclavian Aneurism treated by Temporary Compression direct to the Artery"; Mr. Henry Lee, "Sequel to a Paper on Excision of the Ankle-joint".

WEDNESDAY.—Hueterian Society, 8 P.M. Mr. Durham, F.R.S., will read a paper "On some Symptoms of Organic Disease"; and Mr. Clement Lucas will exhibit a Plastic Operation of the Eyelid.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

We shall feel obliged if Dr. W. N. Hiron (Brussels), whose letter on Medical Degrees and Titles appeared in our issue of March 6th, will forward us his present address.

THE PREVENTION OF QUACKS.

SIR.—In your issue of the 17th inst., Mr. D. A. O'Sullivan, of Burnley, recommends to the consideration of the profession "the propriety of providing some official organisation whose special object would be the prosecution and punishment by law of quacks and pretenders." Everyone will, I think, agree as to the need of such an organisation: but I fear that medical men generally are too apathetic to admit of the idea being carried out very successfully.

In November last, you, as well as your contemporaries, the *Lancet* and *Medical Times and Gazette*, courteously published letters from me suggesting the formation of a "Medical Defence Association", for the purpose of prosecuting unqualified practitioners. Although my letters must have been read by several thousands of medical men in London and the provinces, only a dozen, chiefly country practitioners, responded to my appeal to join me in the movement. Subscriptions amounting to *twelve shillings* were sent in aid of the object (which I now hold), and a further sum of £ 6s. 6d. promised. This being far too small a sum to meet the preliminary expenses of starting such an Association, I have taken no further steps in the matter; but I am very reluctant to let the idea drop altogether, and still hope that something might be done in this direction. Were ten medical men practising in London to send me their names, and express their willingness to join the Association, I would call a meeting for the election of officers forthwith. The association once formed, numbers of provincial medical men would doubtless support us, for they, I believe, suffer more than we do from unqualified practitioners.—I remain, Sir, yours very faithfully,

GEORGE BROWN, M.R.C.S., L.S.A.

12, Colebrooke Row, Islington, N., April 19th, 1875.

AN Old Clinic forwards a paper, but omits to send his name or address.

CORRESPONDENTS are particularly requested by the Editor to observe that communications relating to Advertisements, changes of address, and other business matters, should be addressed to Mr. Francis Fowke, General Secretary and Manager, at the Journal Office, 36, Great Queen Street, W.C., and not to the Editor.

MALARIA.

SIR.—I will feel obliged by your allowing me space to make a few remarks on the existence of malaria. To those who, as far as I can understand their theory, wish to do away with the existence of malaria altogether, and to hold that intermittent fever is caused by chills alone, I would beg to put the question, How is it that in the West Indies, under almost exactly similar conditions in regard to climate, while intermittent fever is exceedingly common in some islands and places, it is almost unknown in others? Let me take the following as examples—Demerara, Antigua, Nevis, St. Kitts. Demerara, according to the chill theory, should be free from intermittent fever than St. Kitts, as the temperature is higher, being 86 deg. Fahr. as a mean in the hot season, and 82 deg. Fahr. in the cold (see Parkes on *Practical Hygiene*, second edition, p. 540, while in St. Kitts, even in the leeward, which is the hottest side of the island, at Basseterre, the mean of day temperature, from May to October, is 84.35 deg. Fahr., and from November to April, 81.45 deg. (For figures in support of these observations, and other information about St. Kitts, see a paper by my self on Yellow Fever, in the *Edinburgh Medical Journal*, Sept. 1871. A map of the island is appended.) Yet though in Demerara intermittent fever is so common that almost every white inhabitant suffers from it, in Basseterre it is not at all common, a few cases in the year being all that I remember seeing in several years' practice. But on the windward and coolest side of St. Kitts, the mean top temperatures, taken by myself in 1858-62, at 2 P.M., were—May to October, 83.5 deg.; November to April, 80.15 deg. The ordinary variation of temperature in twenty-four hours was about 7 deg., while the extreme yearly variation was about 20 deg. (70 deg. in February and March during the night, to 90 deg., at 2 P.M. in October, in Basseterre, and 63 deg. to 87.75 deg. on the windward side. Yet intermittent fever was, in my experience, much more rarely seen on the windward side. I have seen cases of simple continued fever from chill, as from a wetting, but never, that I can remember, of intermittent fever. The soil of St. Kitts is a thick loam, the island itself being an extinct volcano. The neighbouring islands—Antigua, about fifty miles away, and Nevis, only ten miles (or only two from land to land)—enjoy exactly similar conditions of climate, which is just as equable in them as in St. Kitts; while the town of Charlestown in Nevis is rather hotter than Basseterre, being more protected from the windward breezes. Yet in Charlestown and to leeward of it, a very severe remittent fever is endemic, and intermittent fever is very common. While on the windward (coldest, side of Nevis, as I have been informed by medical men practising there, it is not nearly so much seen. There are some marshy ponds to the windward side of Charlestown, which emit a very bad odour at times, and the soil is not nearly so deep as in St. Kitts.

In Antigua, intermittent fever is common. The soil there is a very hard clay, cracking deeply under the sun. In Basseterre, there is a square laid out with a garden in the centre, which, about twenty years ago, was a mud puddle. At that time, I have been informed by my father-in-law, the late Dr. Beard, who began practice there nearly forty years ago, intermittent fever was exceedingly common in the town. The few cases that now occur are generally attributed to malaria from a few acres of marshy land lying to the east of the town, about half a mile out of it.

If chill could produce fever and ague, sailors working all day in the heat of the sun (which I have seen 130 deg. Fahr.), and exposed at night in all manner of ways, should be very subject to the disease; but I never remember seeing a case among them in Basseterre Roads, where the ships are about four hundred yards from the town, and three quarters of a mile from the marshy lands I have spoken of.

I suffered from intermittent fever after spending one night in Antwerp in 1866. It returned three weeks afterwards, after a ride along the low-lying damp valley of the Eden, near Copar, after nightfall, although I was not chilled. Since then, the only threat I have ever had of a return was a chilliness like a band of ice round the waist, coming on at the same hour every day for a few days in and after leaving St. Thomas's "harbour" on a voyage home in June 1871, under circumstances in which getting a chill was simply an impossibility (in fact, even to have felt cold would have made me think myself in the seventh heaven), as I had to sleep with the thermometer at 86 deg. (I have seen it in the same harbour 88 deg. at midnight). The steamers lie very near the shore in St. Thomas's harbour, which is surrounded by land on three sides.

Leaving the West Indies, I would ask, Has Edinburgh become warmer in climate since the North Loch was drained, or are its inhabitants less likely to be chilled by the biting north-easters which sweep through it? Yet intermittent fever is now utterly unknown in it, while it was quite common last century. Again, are the inhabitants of London north of the Thames less liable than formerly to be chilled? or why was ague common there two centuries ago, and not now, if chill be the only cause of the disease?—I am, yours faithfully,

W. MUNRO, M.D., C.M., Late Med. Off. St. Kitts, W.I.

DR. BEVAN.—The charge seems to be one of simple dishonesty against the office. A county court summons appears to us to afford the simplest remedy.

MATERNAL IMPRESSIONS.

SIR.—The case of deformity, reported in the JOURNAL of April 10th, by Mr. Sandham, so closely resembles one which occurred in my practice a short time ago, that it may be worth while to record it, too, in your columns.

In my case, the right upper extremity seemed perfect to the wrist; but the hand was represented by a single finger—apparently the index finger. The left upper extremity was precisely like it; only the forearm was flexed upon the arm, and held there by continuity of the skin only of the two joints. The child was born at the full time, of healthy parents, who had already had one well formed child. It died at three weeks, never having shown signs of possessing much vital energy. The mother did not attempt to account for the deformity, but very pointedly expressed her surprise and disgust at such a result of so much time and trouble.

Islington, April 12th, 1875. I am, etc., J. ASHBURTON THOMPSON.

I. M'A. writes that he has been in attendance on a poor woman who gave birth to three children, and has been requested to find out whether she is entitled to Her Majesty's benevolence, and to whom she should apply.

* Write to Her Majesty's Secretary at Windsor Castle, stating the case fully.

The author of a letter signed "Licensed House", omits to furnish his name and address.

NOTICE TO ADVERTISERS.—Advertisements for insertion in the *BRITISH MEDICAL JOURNAL*, should be forwarded direct to the Publishing Office, 36, Great Queen Street, W.C., addressed to Mr. FOWKE, not later than *Thursday*, twelve o'clock.

DR. RUMSEY, F.R.S.

SIR,—I have read with much pleasure in your *JOURNAL* of 3rd inst., the letter of Dr. Farr, wherein he brings before your readers the great claims which that most eminent sanitary reformer, Dr. Rumsey of Cheltenham, has upon the sympathies of the medical profession and the public at large. We have abundant evidence in his own writings and in reports of Parliamentary proceedings, that he has been labouring in that most unselfish of all undertakings, the cause of sanitary reform, for more than thirty years—the best part of a man's life, nor were his disinterested exertions limited to the area that bounds Dr. Farr's enlightened administration; for, when in 1861-62, the then sanitary reformers of Ireland were battling for scientific registration of vital statistics, Dr. Rumsey threw himself into the struggle, his sympathies crossed the "melancholy ocean" which separates (if I may use the expression) the United Kingdom; and, by his exposition of the true principles which should guide legislation on the subject, he influenced, to a great extent, the nature of the final settlement. During that discussion, I can personally vouch for it, he spared neither time nor trouble, he even writing his correspondence, and every letter might be accepted as a treatise upon the subject matter contained. His great desire was that, as we in Ireland were establishing, for the first time, a national system of registration, that sound principles might from the first moment be recognised, and that the very faulty system then prevalent in England might in time be improved by comparison.

It would not be right to omit the fact that the dispensary medical men of Ireland individually are indebted to him, to a certain extent, for the addition to their incomes made from registration fees. It cannot be forgotten that, in the Bill introduced by Sir Robert Peel and Mr. Clive in 1862, the duties of registrar were directed to be performed by the sixty constabulary, and those of superintending registrar by the inspectors and subinspectors of the district. Notwithstanding the opposition on the part and otherwise of the medical men of Ireland, the authorities appeared determined to carry out their scheme as embodied in the Bill, and only yielded after receiving a deputation from the Social Science Association, nominated principally by Dr. Rumsey. It is but justice to Sir R. Peel to state, that although having a hereditary leaning to the constabulary force, he showed himself on that occasion open to conviction; and after paying every attention to the reasons assigned by the deputation, he said "I am before leaving," "Gentlemen, you have succeeded; I cannot grant all you wish; on grounds of economy, the Poor-law clerks must be the superintending registrars, but the dispensary medical men of Ireland shall have the primary registration of births, deaths, and marriages."

I have not any doubt, sir, that if proper steps be taken, Dr. Rumsey's services in the cause of public hygiene would be fully recognised. I shall be happy to do anything in my power to further the movement, to which I most heartily wish every success.—I am, Sir, your obedient servant, ALEXANDER HARKIN, M.D.
5, College Street North, Belfast, April 21st, 1875.

ROYAL COLLEGE OF SURGEONS.—The following were the questions in Anatomy and Physiology submitted to the candidates at the primary examination for the diploma of membership of the Royal College of Surgeons on April 3rd, when 180 gentlemen offered themselves.

1. Describe the coagulation of the Blood; and state what is the constitution, physically and chemically, of the component parts into which it is resolved when coagulated.
2. Describe the distribution of the Pneumogastric Nerve in the Thorax; and state what are its functions in regard to the thoracic Viscera.
3. Describe the articulations of the Atlas with the Occipital bone and the Axis; and the Ligaments connecting these bones.
4. Give the attachments and nervous supply of each of the Muscles which flex and extend the Thumb.
5. Describe the course, relations, and anastomoses of the branches of the Facial Artery which arise below the inferior maxilla.
6. In making a longitudinal section of the Encephalon in the median line, enumerate the parts divided, in their order, from above downwards.

J. M. H. M. (St. Helen's).—Mr. Renshaw, 356, Strand, W.C.

H. B. C. asks for the names of any other hospitals or infirmaries, besides Carlisle and Leicester, that offer dresserships, etc., to senior students.

CORONERS IN IRELAND.

SIR,—Will you kindly reply, by way of answer in your *JOURNAL* of next week, to the following query? Is an Irish coroner paid according to the inquests which he conducts, or by a stated salary? Your kind attention will much oblige
Merthyr Tydfil, April 16th, 1875. Your obedient servant, J. Lowe.

*. A coroner in Ireland is paid £1. 10s. for each inquest held by him since the preceding assizes, or since his last application for a presentment, but not to exceed £50 at each assizes. The coroner is entitled to charge 6d. a mile for every mile travelled going to hold an inquest, but nothing for returning. The coroner may also charge 6d. a mile for visiting a place to inquire if an inquest is necessary.

P. B. SHIPLEY AND PRUSSIC ACID.—In *Trelawny's Recollections of the last days of Shelley and Byron*, the former asks: "You, of course, enter into society at Leghorn, should you meet with any one of the person capable of preparing the prussic acid, or essential oil of bitter almonds, I should regard it as a great kindness if you could procure me a small quantity. It requires the greatest caution in preparation, and ought to be highly concentrated; I would give any price for this medicine; you remember we talked of it the other night, and we both expressed a wish to possess it; my wish was serious, and sprung from the desire of avoiding needless suffering. I need not tell you I have no intention of suicide at present, but I confess it would be a comfort to me to hold in my possession that golden key to the chamber of perpetual rest."

DR. GRIFFITH'S paper only waits for space, on which, as he will have observed, there has been for some weeks unusually great pressure.

We will communicate privately with Dr. Ross and Mr. Bradley on the subject of their letters. In one way or other we shall be able to meet their wishes.

UNAUTHORISED SIGNATURE.

SIR,—I shall be glad if any of the readers of the *JOURNAL* can inform me whether the signing of a certificate under the following circumstances is a forgery punishable by law. A. left his practice in the charge of B., and, before leaving, gave B. instructions to sign all certificates in his A.'s name. Following out these instructions, B. signed a death certificate in the name of A. instead of his own, although A. had never seen the case.—I am, etc., P.R.C.L.
April 16th, 1875.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the *BRITISH MEDICAL JOURNAL*, should arrive at the Office not later than 10 A.M. on Thursday.

ON THE INFLUENCE OF TEMPERATURE DURING CHILDBIRTH.

SIR,—Motion and temperature are correlative; and it may be regarded as an axiom that no great work, whether of the mind or body, can ever be accomplished with the highest degree of efficiency, unless throughout accompanied by a great and general exaltation of the corporeal temperature. Parturition, instead of being an exception to this universal law of nature, is, as regards the body, the grandest expression of it.

We read in the book of Exodus that, when Pharaoh ordered the midwives to kill all the male children of the Israelites, the latter gave, as the reason of their inability to do so, the following reply: "because the Hebrew women are not as the Egyptian women; for they are lively, and are delivered ere the midwives come in unto them." Now, unless this statement is to be regarded as a mere subterfuge, there must be some peculiar reason why the Hebrew women should be so lively and rapid in the process of delivery; and it may fairly be assumed that their occupation of making bricks (which involved great bodily activity and a high temperature) was the cause. Had the sacred historian been inspired with further details concerning the labours of the Hebrew women, we should doubtless have been informed that, at that period, by virtue also of the liveliness of their faith and hope, they enjoyed a comparative immunity from the pains and perils of childbirth. Indeed, we can never sufficiently admire the wonderful courage displayed by that remarkable people, "whose lives," we are told, "were made bitter with hard bondage in mortar and brick, and in all manner of service in the field"; but who nevertheless "were fruitful and increased abundantly, and multiplied and waxed exceeding mighty, and the land was filled with them"; in all this forming a most striking contrast to the aborigines of various nations whom colonists (to use an Americanism) have crowded out. For there can be but little doubt that when the spirit of a nation is broken, the women become thereby peculiarly liable to succumb to all sorts of abnormal conditions which then display themselves with ever increasing frequency during pregnancy and childbirth. The writer was informed, some years since, by Dr. Leeson (who is now practising at Vevey in Switzerland), that when he resided at Buenos Ayres, he attended, during the revolution, several cases of placenta prævia, which most dangerous and unusual complication could only be traced to anxiety of mind.—I am, etc., M.D.
Harsleden, April 1875.

VACCINE.—We fear nothing can be done to stop the circulation of the mischievous misstatements circulated by Mr. W. Young in the name of the Society for Suppressing Compulsory Vaccination; but it would, we think, be desirable if one of the societies for diffusion of sanitary knowledge were to print and publish, at a very cheap rate, a short and effective answer to the post-card which Mr. Young circulates, demonstrating the fallacies on which this misguided Society relies.

We will make inquiries for Mr. Heane (Cinderford).

HANDBOOKS FOR MEDICINES.—Dr. H. F. Smith writes to remind us that there exists in the English language a Handbook for Medicines written by him, and published by Longmans and Co. It is, we believe, a very useful and reliable little book.

AN Anticontagious Diseases Acts paper, called *The Medical Inquirer*, is being issued monthly to promote the repeal of the Acts. It quotes the letters of Dr. Nevins at length from the columns of the *BRITISH MEDICAL JOURNAL*, but omits the refutations of Dr. Parkes, Inspector-General Lawson, Dr. Ffolliott, Dr. Myers, etc. This it does to remedy the "onesidedness" of the medical press, which is, indeed, its principal *raison d'être*.

We are indebted to correspondents for the following periodicals, containing news, reports, and other matters of medical interest:—*The Croydon Chronicle*; *The Newcastle Daily Journal*; *The Derby and Chesterfield Reporter*; *The Hampshire Telegraph*; *The Newton Directory*; *The Hereford Times*; *The Hackney Express*; *The Liverpool Mercury*; *The Glasgow Herald*; *The Scarborough Gazette*; *The York Herald*; *The Scarborough Mercury*; *The Scarborough Express*; etc.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

Dr. R. J. Lee, London; Dr. H. Parsons, Goole; Dr. John Dougall, Glasgow; Mr. Alfred Ashby, Boston; Dr. Galahin, London; Dr. R. H. Semple, London; Dr. Chas. Lees, Bombay; Mr. J. Chater, Tenby; Dr. Parkes, Southampton; Mr. J. Edward Schön, Kilburn; Mr. C. Dukes, Rugby; Mr. E. T. Burton, Birmingham; Mr. E. Noble Smith, Paddockhurst; Mr. G. Brown, London; Dr. J. Haddon, Manchester; Dr. McCall Anderson, Glasgow; Mr. J. Woodman, Exeter; Dr. J. W. Langmore, London; Mr. E. Atkinson, Leeds; Dr. Twyford, St. Helen's; Dr. Herbert Snow, London; Dr. Tilt, London; Dr. Trollope, St. Leonard's; Mr. L.H. Blenkarne, Buckingham; Dr. Rabagliati, Bradford; The Secretary of the North London Society: Mr. Clarke, Abingdon; Mr. J. Lowe, Merthyr Tydfil; Dr. Balthazar Foster, Birmingham; Dr. Copeman, Norwich; Dr. E. Holland, London; Mr. T. Holmes, London; Mr. Edward Swain, Arlesey; Dr. J. W. Moore, Dublin; Mr. H. C. Burdett, Greenwich. Our Dublin Correspondent; Our Edinburgh Correspondent; Mr. H. M. Lawrence, Hadlow; Mr. H. E. Smith, London; Dr. Jackson, London; Dr. A. B. Steele, Liverpool; Mr. G. Field, London; Mr. P. S. Gaye, Newton Abbot; Dr. Horne, Scarborough; Mr. Robinson, London; Mr. Heane, Cinderford; Mr. Marriott, Kibworth; Dr. Hardie, Manchester; Dr. Stevenson, Edinburgh; Mr. W. D. Napier, London; Dr. T. S. Dowse, London; Dr. John Harley, London; Mr. Spencer Wells, London; Mr. S. M. Bradley, Manchester; Mr. F. Mason, London; Mr. Poole, London; Mr. John Morris, Brighton; Inspector-General Lawson, London; Mr. C. De Gorreque Griffiths, London; Mr. R. S. Fowler, Bath; Mr. E. C. Board, Clifton; The Secretary of the Royal College of Surgeons of Edinburgh; Mr. T. Hopwood, Sunderland; Dr. R. H. Allnatt, Frant; Dr. P. S. Fentem, Bakewell; Mr. W. F. Clarke, London; Dr. T. K. Bevan, London; Dr. Ross, Waterfoot; Mr. Wilson, Walsend; The Secretary of the Apothecaries' Hall, London; The Secretary of the Moultsford Lunatic Asylum; Sir George Burrows, London; etc.

CLINICAL REMINISCENCES.

By ALEXANDER HARVEY, M.D.,

Professor of Materia Medica in the University of Aberdeen, and Consulting Physician to the Aberdeen Royal Infirmary.

I.

Case of Malacosteon, leading to Extreme Approximation of the Rami Ischii, and rendering labour (which supervened) "per vias naturales" impossible.—(Extract from Case-Book, August 5th, 1844.) Mrs. Wood, aged 38, married, and the mother of nine children, residing at Dam of Gilcomston, Aberdeen, applied to me in the autumn of 1843, on account of certain dyspeptic symptoms with which, she said, she had of late been troubled. Her general appearance at that time was sufficiently remarkable to attract attention. It was that of a person whose general health had been much broken by long previous illness. On inquiry, I learnt that she had had what she described as chronic rheumatism for a period of four or five years, during which time she had never at any time been altogether free of it. This affection she ascribed to an exposure to cold shortly after one of her confinements. Twelve years ago, she had an attack of acute rheumatism, from which she recovered perfectly. The pain or pains of that so-called chronic rheumatism affected various parts of the body, but chiefly the back and right shoulder. Within the last two or three years, both sides of the chest had undergone a marked change of form. She had a spare sallow countenance; had lost much of her flesh and strength, but was able to move about and discharge her household duties. She had borne a family of nine children, the last about six months before I first saw her. On this occasion, as on all previous occasions, her labour was easy and quick. She was now nursing her youngest child. For the rheumatic affection, she had tried a great variety of remedies; but, none of them having done her any good, she had for a long time given up using anything. And, as she did not now consult me for it, my advice to her was confined to recommending her to give up nursing (which she did), and to prescribing for her dyspeptic symptoms, which ceased to trouble her in the course of a week or ten days.

After this, I did not see her again (save casually once or twice) till the beginning of the following year (1844), when I was sent for to see her infant child, and which I had occasion to attend for six or eight weeks. During her child's illness, she had herself an attack of bronchitis. This, with the attendance on her child, added to the shock given her by the drowning of a boy in a sheet of water hard by her own house in the month of December previous, and the excitement attendant on a prolonged attempt in her house to effect the boy's recovery, weakened her exceedingly. On the removal of the bronchitis, and the recovery of her child, she went to the country, from which after a time she returned a good deal improved.

She continued much in her usual (infirm) state of health till the beginning of May, when she was again seized with bronchitis. This attack was much more severe than the former one, and lasted about six weeks. It was attended throughout by sleeplessness, and, when the weather was at all warm, by profuse perspirations; and both these continued till the time of her death. After the bronchial affection had subsided, she had occasional attacks of very severe pain, sometimes in one, sometimes in another part of her chest and back. These in general lasted only for a few hours, and yielded readily to fomentations and opiates.

About this time (May 1844), she informed me that her right collar-bone had gone out of joint some weeks before. On examination, this was found to be the case, the dislocation being at the scapular end of the clavicle. The shoulder had since become much more prominent, and she had but little use of the arm.

When I first saw her on this occasion (May), she informed me that she was again in the family way, and expected her confinement about the end of June. She had her menses last in the first week of October. She had engaged a midwife to attend her, but intimated a wish (suggested by her weak state of health) that I should be in attendance also, if required.

Her last attack of illness had reduced her to a state of great weakness, and she was apprehensive that either she would not live to be confined, or have strength for it should she do so. She continued, however, much as she had been for many weeks till within the last few days of her life, when her breathing became quick and oppressed, and

her pulse habitually accelerated. The day before she died, she stated that she had not felt the movements of the fœtus for twenty-four hours. In the evening of this day, her pulse and breathing became still worse: she was restless and anxious, and apprehensive of the worst. Next morning, she was still worse, and began to sink as the day advanced. When seen by me in the afternoon and evening, she was seemingly moribund. At 10 P.M., while sitting up out of bed, she had a well marked labour-pain, the waters came off, and she died about half an hour afterwards.

No examination *per vaginam* was made till about a fortnight before she died. The examination then made was, from her posture, an imperfect one, and only a single finger was introduced. Nothing preternatural, however, was detected in the state of the parts; and this, taken along with the circumstance of her having had an easy delivery eighteen months previously, removed all apprehension as to the condition of the pelvis.

During the last three months of her life, though very weak and her belly large, she was unable to assume the recumbent posture, even in bed, for any length of time. This was owing to the state of her breathing, and not less to the pain she felt in the back on assuming that posture. Her posture, as well in bed as out of it, was mostly the sitting, with an inclination to the left side. No doubt this posture, habitually maintained for so long a time, with the weight of the gravid uterus, contributed materially in her weak state of health, or rather, in the special constitutional state in which she then was, to bring about what was afterwards ascertained to have been then in progress; viz., the approximation of the tuberosities and of the *rami ischii*.

The morning of the day she died, she was seen along with me by my colleague the late Dr. Dyce, then lecturer, afterwards professor of midwifery in the University of Aberdeen. Her utter prostration was such as to make me exceedingly anxious about her. I was now coming to realise her own often expressed idea, that, should she reach her time, she would not be equal to the occasion.

In the circumstances, it seemed to Dr. Dyce desirable that labour should be artificially induced. With that view, he made an examination *per vaginam*. By reason, however, of the approximation of the tuberosities and rami of the *ossa ischii et pubis*, he failed to reach the orifice of the womb. In fact, it was all he could do, and this after firm boring pressure, to get his finger a little way into the vagina. We left together, to consider what should be done; but neither of us could see his way. As already stated, when seen by me in the afternoon and evening of that day, she was to all appearance moribund, and she died that night at 10.30.

On examination of the body after death (Dr. Dyce superintending), the uterus and its appendages were found healthy. The fœtus, a well formed female, seemed to have reached the full term. The general aspect of the pelvis was pretty much that of the "obliquely distorted pelvis" figured in Dr. Rigby's *System of Midwifery* (Library of Medicine), page 189, without, however, the elongation in the antero-posterior direction there shown, and with a singularly marked approximation of the tuberosities of the ischium, narrowing the space between the rami of the pubes and ischium. This approximation was such and so great as to admit the passage of only a single finger into the vagina. It was impossible to get three fingers in line any distance into the vagina. The linea ileo-pectinea was somewhat irregular; there were slightly projecting points of bone at the part of the line opposite the acetabula, and this did not correspond with the line of the promontory of the sacrum, the latter, on the right side, being situate lower down. The promontory, however, did not appear to be thrown forwards. The condition of the tuberosities and rami somewhat resembled that represented in a figure given at page 187 of Dr. Rigby's book, already referred to.

My impression, however, as to this, is now (March 1875), that the rami were more straight, and the approximation much greater than is there figured. Altogether, the virtual obliteration of the passage by the pubes was singular and very striking. Year by year, Dr. Dyce referred to this case in his lectures as the most extreme case of narrowing in that direction he had ever met with or had seen recorded. Delivery *per vias naturales*, even with instruments of any kind, was, it was clear, absolutely impossible. Had the patient lived, it could only have been effected by the Cæsarean section.

I need not trouble on the readers of this JOURNAL any reflections on the case now recorded. I regret that I was not sufficiently alive to what was going on secretly "in the hidden part," and that I did not consult Dr. Dyce sooner. The dislocation of her collar-bone, and other circumstances, might or should have awakened my suspicions, but they did not; while the facts, that she had so long been the subject of "chronic rheumatism", and yet during it had borne children easily, and the last only a year and a half before; and further that, but a

fortnight before her death, the vaginal examination revealed nothing amiss, misled me. It was, indeed, a very cursory examination. Her posture, however, and her whole general condition, precluded its being made thoroughly. It would have added to her distress and suffering. Yet one cannot well doubt that, at that stage, a proper examination would have revealed something very far amiss. I ground nothing in extenuation of any fault attaching to me in respect of the management of this case, that I was not the poor woman's engaged accoucheur; I was her medical attendant, and, as such, responsible for everything in relation to that affair. But time ran on: things went on, and they ended disastrously for my patient, without, I would fain hope, any blame (all things considered) being fairly chargeable upon me. It is easy to be wise after the fact; yet what should have been done? And when or at what stage?

I regret that the particulars above recorded, as to the actual condition of the pelvis, should not be more precise. For many years, they were familiar to me, and I thought they could never pass from my recollection. But, after thirty years, I cannot recall them more precisely. What, however, I have given of the case is from notes taken at the time and now rigidly transcribed. Nor would these now see the light but for an eminent professor of midwifery, to whom they have been submitted, and who assures me that, "fragmentary" as they are, they "should not be lost", the case, as it stands, being "a most striking one".

REPORT OF A CASE OF APHASIA.*

By a Committee of the Glasgow Pathological and Clinical Society (W. T. GAIRDNER, M.D.; ALEX. ROBERTSON, M.D.; and J. COATS, M.D.).

CLINICAL NOTES BY DR. GAIRDNER.—Mrs. Williamson was first admitted to the Glasgow Royal Infirmary on October 10th, 1868, suffering from a well-marked hemiplegic and aphasic attack, in which the loss of language was so complete, that absolutely no information whatever could be obtained as to her sensations and the degree of her intelligence. The expression of her face showed that there was neither coma nor lethargy, but the only sounds she uttered for some time after admission, were, "Oh, dear!" with much moaning, and a sound like "hey", which she repeated over and over in a purely mechanical way, without the least apparent significance. The right side was almost completely paralysed, and she could not, or would not, protrude the tongue. The pupils were normal. The bowels were costive. She had a pretty severe cough, with mucous rales on the right side of the chest. When evacuations took place, they were made into the bed.

On October 13th, the state was nearly the same; but the formula of utterance was a constant repetition of, "I bud—bud—bud", whenever she was spoken to, or wished from any cause to give notice of anything. At times, she insisted on this formula with great vehemence and many repetitions; at other times, it was "I", or "Oh", alone, and sometimes she was quite inarticulate.

It was observed at this date that, while no merely verbal request to put out the tongue appeared to be understood if unaided by visible signs, it was always possible to obtain a response to these latter; and this continued long to be the case, although afterwards, in this as in other respects, there was a distinct improvement.

A synopsis of the whole observations, written about a month after this (November 13th), gives a tolerably complete view of the state of the patient during the earlier period of the case.

"1. There is, on the whole, a marked and gradual improvement in the state of apparent intelligence.

"2. To judge from the eye and gestures, this woman is quite the reverse of stupid or apathetic. She is rather quick and eager to communicate, and had several times been moved to tears by her inability to do so.

"3. In remarkable contrast with the above, she has never, at any time, articulated a continuous sentence, or been able to convey effectually her wants, although her most immediate friends and neighbours have visited her with the object of eliciting them. She has on no occasion given notice of any of her discharges, and has passed everything in bed.

"4. Her vocabulary since last report was, for a long time, limited to the words, 'Doctor, doctor', or 'it's doctor', or 'you're doctor, doctor'; and these words she repeated with gestures and looks which seemed to imply that she wished them to convey a great deal more. Frequently, the incongruity of this attempt and of the result would strike her, and she would break into a laugh. At other times, the

emotion would be of a different kind, and she would alternate these with 'Dash it!' while, on other occasions, she has muttered bits of phrases, words with 'Oh! oh! oh!' evidently a sign of disappointment and vexation.

"5. It cannot be distinctly affirmed that she has clearly understood anything spoken to her, except in so far as the general sense may have been apparent to her through surrounding circumstances and gestures. . . . It has always been nearly impossible to get her to protrude her tongue . . . except by sitting opposite to her and making very pointed signs repeatedly, and with great emphasis . . . the tongue being in this case protruded as far as the teeth, but in no instance further.

"6. On the other hand, in any words that have fallen from her, there has not been the least trace of the special forms of indistinct utterance that usually go along with paralysis of the tongue. . . . She has, on one occasion, said quite distinctly, "Doctor, has no seen me to-day"; on another, has been surprised into the exclamation, not intelligible, but sufficient to demonstrate increasing power over the parts of speech."

After this, the gradual education (for such it was, though very slow and unsatisfactory) of her verbal faculty proved a constant source of interest; and, on many occasions, Dr. Gairdner and others sat at her bedside for a considerable time testing her power both of apprehending and pronouncing names. Her own name came first into notice, and, by persistently repeating to her successively, e.g., "Robertson, Jacobson, Jamieson, Richardson, Williamson, etc.", she was gradually brought first to recognise by signs, by simple "No", and "Yes"; and then, after a while, to pronounce her own surname, though she always required the leading above-mentioned in order to do so. She also (but whether in answer to suggestions or not, is a little uncertain) gave her age as "sixty—under—two"; whether this meant fifty-eight or not remained undisclosed. Some time afterwards, she got hold somehow of the name of "Dr. Gairdner", and she soon adopted it as one of her formulae, which she retained, alternating with others, to the very close of her stay in the Royal Infirmary. One of these others was curious, and she seemed to come upon it suddenly, no one knew exactly how. In the midst of her usual scraps of words and phrases, she often interpolated, "God, ay, God up a stair"; and whether in this there was any obscure consciousness of heaven or of anything above her, it was impossible to discover; for, at times, she seemed to alternate this expression quite mechanically with others of no significance. The paralytic condition improved somewhat, and she was able to sit up for some time before her removal to the Town's Hospital. She was able also, for the most part, to control her sphincters better, and she became more voluble in the use of some of her phrases, but not in any essential degree more spontaneous or intelligent in the use of language.

CLINICAL NOTES, IN CONTINUATION, BY DR. ALEXANDER ROBERTSON.—This patient died on December 26th, 1874, being then sixty-seven years old. She was admitted into the Town's Hospital on June 21st, 1869, having been discharged on that day from the Royal Infirmary, where she had been under Dr. Gairdner's care for a considerable time. She was constantly resident in the Town's Hospital from the time of her admission till her death.

Mental Condition.—During the whole time she was under my observation, there was no appreciable difference in the state of her mind. In the *Glasgow Medical Journal* for January 1871, I have published a note of her case in a paper on Aphasia, and the remarks there made regarding her speech and the condition of her mental faculties generally are fairly applicable to her during any period of her residence. I shall, therefore, simply quote them.

"I have a case under my care at present which fully illustrates the latter statement (regarding amnesia, i.e., amnesic aphasia). The patient is an elderly woman, who has been amnesic for some years. Her stock of language at present amounts to 'Say a grace', and 'Doctor up the stair in our house', either of which she utters, apparently indifferently, in reply to any question that may be put to her. Upwards of a year ago, when she was first admitted into this institution, she was wont to ejaculate 'Dr. Gairdner' in the same meaningless way. I concluded that this gentleman's name occurred to her by an impression having been produced on her feeble memory (or, if we accept Dr. Bastian's theory, on her damaged 'auditory perceptive centre') through its frequent repetition in her hearing while under his care in the Royal Infirmary of this city. Although she seems to understand what is said to her, her intelligence is in reality extremely defective, as, when I ask her to take off her cap, give me a pin, or make any other simple request, she usually looks puzzled, and fails to comply with my wish. Yet this woman can pronounce all ordinary words, and even short sentences, with great readiness, directly after she hears them, though she commonly blunders the articulation of the

* Read before the Glasgow Pathological and Clinical Society, February 9th.

latter half of big words." There was, however, a slight change in her stock phrases. She gradually stopped repeating the one beginning with 'Doctor' and 'Dr. Gairdner', substituting occasionally 'Margaret Williamson', her own name. There was an absence of the painful emotional excitability which is often associated with severe hemiplegia not complicated with aphasia; but she sometimes burst out into a loud though not a prolonged laugh when addressed, there being nothing in the observation to give rise to it.

Bodily Condition.—During the first year of her residence, there was a slight improvement in the power of her right extremities; but after that there was no further change. Till shortly before her death, with the assistance of the nurse, she got dressed, and sat by the fireside most of the day. She could stand, and even drag the leg two or three steps in walking. The arm was more powerless, though she could move the fingers a little. It was much atrophied, and the flexors were contracted, so that the fingers were bent well on to the palm of the hand. There was no deformity of the face either in her ordinary expression or when she laughed. The cause of death was gradual progressive encephalment with diarrhoea.

PATHOLOGICAL REPORT BY DR. ALEXANDER ROBERTSON AND DR. JOSEPH COATS.—The lesion to be described existed on the left side of the brain; the right being apparently normal, apart from some irregularity of the convolutions. The left cerebral hemisphere was very much shrunk, the shrinking depending on a loss of substance in its middle parts. There was a large gap in the cerebrum, occupied (in the brain as preserved in spirit) by a collapsed membrane, which was stated to have contained, at the time of the *post mortem* examination, a large quantity of fluid. This collapsed membrane occupied the situation of a considerable number of convolutions. More precisely described, the following was the condition of parts. 1. In the frontal or anterior lobe, the superior or first frontal convolution was present almost in its entirety, it being doubtful whether it was not undermined at its extreme posterior part. The middle or second frontal was also nearly entire; at most, the extreme posterior part being absent. The third or inferior frontal was distinctly destroyed at its posterior part. The portion behind and above the ascending ramus of the fissure of Sylvius being entirely wanting. From the absence of the posterior

The shaded parts indicate the extent of the lesion.

part of the inferior frontal and of the ascending frontal, including the operculum, the island of Reil was exposed and visible without separation of the parts. 2. Of the parietal lobe, the only part present was the posterior half of the superior parietal lobule (Ecker); that is to say, the ascending parietal convolution, the anterior half of the superior parietal lobule, and the entire inferior lobule, including the supra-Sylvian and the angular gyri, were destroyed. It was even doubtful whether the destruction did not extend partly to the middle parts of the occipital lobe. 3. The upper parts of the temporal lobe were destroyed, including the superior temporal convolution, and a portion of the middle temporal, perhaps the whole of it.

From the state of the brain, it could not be accurately determined whether the corpus striatum and optic thalamus had been much interfered with. The island of Reil was intact, and this might be taken as presumptive evidence that the lesion had not extended to the corpus striatum. The surface of this ganglion was smooth, and it was doubtful whether it was smaller than the right. The optic thalamus was nearer the altered portions, and its external parts seemed partially lost.

ON THE MEDITERRANEAN COAST OF THE SOUTH OF FRANCE IN ITS MEDICAL ASPECT.

By WILLIAM MARCET, M.D., F.R.S.,

Late Assistant-Physician to the Westminster Hospital and to the Hospital for Consumption and Diseases of the Chest, Brompton.

II.

IN a former communication (BRITISH MEDICAL JOURNAL, March 6th, 1875), I entered on the medical history of those consumptive patients who are usually sent to winter on the Mediterranean coast. I also attempted to trace the influence of the southern climate on the progress of phthisis, insisting at the same time on the careful selection of the site for the residence in each individual case, especially with reference to elevation above the sea-level.

My present object is to inquire into the physiological influence of differences of atmospheric pressure upon the human body. It is now, I think, generally acknowledged that altitude is a very important consideration with respect to the residence best suited for consumptive invalids. Of course, the Mediterranean coast does not afford means of treating phthisis in such high places as St. Moritz or Davos, which are admirably suited for a summer sojourn; but it unites a certain elevation above the sea with a mild temperature well adapted for a winter resort.

Such a thing as a perfect climate is not to be met with anywhere; at all events, certainly not for human beings. With regard to the vegetable kingdom, some trees, such as the Wellingtonia in California, and the Eucalyptus in Australia, appear to be possessed of a wonderful longevity. On the Sierra Nevada in California, there are, as many of my readers are aware, Wellingtonias (*Sequoia gigantea*) considerably over a thousand years old, and bidding fair to live for another thousand years to come. With these wonders of Nature, the climate, I may say, is as nearly perfect as possible. In the autumn of 1873, having visited one of these remarkable groves (the Mariposa), I found by walking round one of the trees and counting the number of steps, that its circumference measured approximately over one hundred feet, including of course, the immense projecting roots. The tree called the Grizzly Giant, seven and a half feet above ground, has been ascertained to have a circumference of seventy-eight feet and a half; and another observer estimated its height at nearly three hundred feet. By counting the number of rings on the stump of one of the trees which had been cut down at a height of six feet, it was found to be thirteen hundred years old (*Tourist's Guide, Yosemite*). An idea of the size of the trees may be formed from the fact that in the hollow trunk of one of them I stood on horseback, side by side with three other riders; and I passed on horseback through the hollow trunk of another which was rotting on the ground. There are other smaller Wellingtonias in company with the giants; but they look so much their juniors, that they will have to outlive many centuries before they can aspire to be considered as big trees.

If I have alluded to the present subject, it is to observe that the climate of the home of these enormous Wellingtonias must be wonderfully adapted to their longevity. Indeed, there appears no reason why they should die at all, except from the hand of man, who will everywhere impose himself upon Nature and turn her to his advantage. The enormous stores of heat which probably thousands of years have accumulated on the Sierra Nevada have already been made use of by the Indians, and many of the trunks of the big trees left standing have been hollowed out by the action of fire long before the white man knew of their existence. It is our business, in a medical point of view, to ascertain the cause of this extraordinary prolongation of vegetable life. First of all, it will be observed that all circumstances unite towards that object. The atmosphere of these mountains is pure and dry; I believe it is never foggy. The rainfall is inconsiderable; the summer is dry, and never very hot; while the winter is never very cold. There are hardly ever any thunderstorms in those parts; and I was told by a person inhabiting Clarke's farm, the nearest habitation to the Mariposa grove, that, during a residence of three years in that locality, not more than two or three thunderstorms had occurred. The approximate height of the Mariposa grove above the sea is, I believe, between five and six thousand feet. The spot is admirably sheltered from the winds by its position in the Sierra, so that hurricanes and gales of wind are scarcely known in these solitary regions. The soil must supply an inexhaustible amount of nourishment from the remains of thousands of trees which are being turned into food for the support of the giants. Animal life is nearly absent from these forests; there are very few, if any, bears in that neighbourhood; no woodpeckers or insects to destroy the bark and wood, which are said to be protected, moreover, from these agents of destruction, by the presence of a peculiar secretion;

and there are no squirrels to feed upon the fruit of these enormous coniferæ. These trees have been left to grow, fighting an easy battle of life, and feeding upon their weaker congeners, some of them probably for several thousands of years. Their only enemy is the snow, which occasionally falls heavily in winter, and lops off the tops of the trees, or breaks off some of the higher branches.

Before entering upon the influence of altitude upon the treatment of consumption, I must beg to allude shortly to the theory of the interchanges of gases in respiration. In the *Lancet* for February 2nd, 1867, I communicated a letter to the editor explaining how Graham's discoveries on the absorption and separation of gases by colloid septa appeared to me to afford the best means of accounting for the passage of carbonic acid out of the blood and lungs, and the admission of oxygen into the blood through the pulmonary tissue. The phenomenon was described as due to the solubility of carbonic acid and oxygen in the damp pulmonary tissue, and their subsequent movement by physical diffusion—the one out of the blood into the pulmonary alveoli, the other from the alveoli into the blood.

I observed in this communication that the evolution of carbonic acid at the lungs might be considered as regulated by four different conditions: 1. The amount of carbonic acid contained in the blood; 2. The degree of readiness with which the carbonic acid travels through the tissue of the lungs; 3. The temperature of the lungs; 4. The amount of air taken into the lungs at each respiration. I did not at that time allude to another circumstance which clearly has a very important bearing upon respiration; that is, atmospheric pressure. There are two physiological circumstances to be considered in connection with the influence of a reduction of atmospheric pressure upon respiration: 1. The fact that the oxygen in a given bulk of air is proportionally lessened; and 2. That the escape of carbonic acid from the lungs meets with less and less resistance in proportion with a fall in the height of the barometer. The volume of oxygen in a given bulk of air, under different degrees of pressure, has been calculated by the distinguished professor of chemistry Marignac of Geneva, at the request of the well known physician Dr. Lombard, and the table showing the result of these calculations is published in Dr. Lombard's paper entitled "De l'Immunité Phtisique". This table shows that the amount of oxygen contained in a certain volume of air is reduced to one-half at an altitude of 5,000 metres, or 16,404 feet. According to that gentleman, it has been found, from a series of a thousand observations, that at the height of Mexico, 2,227 metres (7,306 feet), there is a daily falling off by 3.48 grammes (5.370 grains) on the amount of carbon transformed into carbonic acid at the seaside. There can be no doubt, therefore, that a much greater quantity of carbonic acid is formed and exhaled at the seaside in a given time than at an elevation above the sea-level. The circumstance relating to diminished atmospheric pressure facilitating the evolution of carbonic acid from the blood at the lungs is very important to notice. We know to what extent the pressure of the air checks the boiling of water; this it does by preventing the formation of steam, or escape of the water in the form of vapour; and just as a diminished pressure opposes less resistance to the boiling of water, so must it also assist the blood in getting rid of the carbonic acid it contains. When the lungs are thickened by disease and supplied with less blood than in health, the importance of such a means of favouring the elimination of carbonic acid at the lungs as diminished atmospheric pressure must be very great. On removing from the seaside to the height of a few hundred feet, a sensation is experienced quite in keeping with the above remark. The air appears lighter, and a feeling of comfort is experienced during the act of respiration which was unknown near the sea. Those who are asthmatic will perhaps be the first to notice the difference; but a similar relief will be experienced in all cases of consumption. Not only will expiration be carried on with greater facility at a certain height above the sea, but the cutaneous exhalation of carbonic acid will clearly be favoured by the very same circumstance. Let anybody enclose his arm in an India-rubber bag partly full of air, as I have done, and, after an hour or even half an hour, draw two or three pints of this air through a solution of barium hydrate in water: a precipitate of barium carbonate will be obtained, much more abundant than that which a similar bulk of pure air would have yielded in the same solution. It is, therefore, very obvious that the skin gives out carbonic acid; and it may be safely concluded that, in cases where the evolution of carbonic acid through the lungs is impeded, the skin takes upon itself the extra work, acting an important part as an organ of respiration. The reverse must also be true; and I have no doubt that circumstances checking the circulation at the surface of the body, such as a sudden accession of cold, must, by calling upon the lungs to do extra work, often be the cause of pulmonary irritation, attended with cough. Cutaneous respiration appears to be so important a function with certain animals, such as frogs, that they

have been known to live for a considerable period after the removal of their lungs. Thus Paul Bert states that Albini (*Sulla Respirazione nelle Rane*) has seen frogs live for a period of a hundred and sixteen days after the excision of their pulmonary organs. (*Leçons sur la Physiologie comparée de la Respiration*, 1870, p. 276). I cannot, therefore, insist sufficiently on the importance of attending to the free action of the skin both as a perspiring and breathing organ. Access of air to the surface of the body should be promoted by every means consistent with protection from cold. Woollen textures, such as flannel, will answer the purpose best. When patients come to me with chamois-leather jackets, perhaps worn over the skin, or leather chest warmers or protectors, I make it a point to advise their being at once given up.

That hæmoptysis is due, in many cases, to a state of malnutrition of pulmonary vessels is, I think, a conclusion at which we must necessarily arrive; and any amount of carbonic acid which may remain in excess in the blood or pent up in the lung-tissue, must assist in keeping up this morbid state; hence, the check hæmoptysis meets with on rising above the sea-level will depend upon an improvement in the nutrition of the lungs due to their parting the more readily with the carbonic acid they contain.

Some people live several hours daily under conditions of pressure which must interfere considerably with their respiration and other functions; I am alluding to professional divers. I had heard that divers, in consequence of their being subjected to sudden and considerable changes of pressure, occasionally bleed at the nose and ears on returning to the surface of the water; and, on meeting a friend last summer who had been engaged with diving operations, the conversation naturally turned upon that subject. What I gathered from this gentleman, at the time, greatly excited my interest; and on reconsidering later the effects of the enormous pressure the body must sustain at a depth of about a hundred feet, I wrote to him, asking him if he could oblige me with a few additional particulars as to the influence of diving upon the body. In the kindest possible manner, he procured and sent me three letters, one from Mr. A. C., late Diving Inspector of Her Majesty's ship *Excellent*; one from Mr. G. C., Diving Gunner, Her Majesty's ship *Excellent*; and one from Mr. J. H., Diver, Her Majesty's Dockyard, Portsmouth. Thus it was impossible to be supplied with information from more trustworthy authorities.

Perhaps, the earliest unusual sensation felt on being lowered under the surface of the water is that of pain in the ears; this first effect of pressure is, indeed, well known to most of those who have gone down in the diving-bell at the Polytechnic Institution. My friend writes, that he has found the act of swallowing his own saliva to afford a marked relief in such cases. He observes, "Your ears, somewhere about the drums, gives a little crack like cracking of the finger-joints, and you feel immediately relieved. The moment you touch the bottom, the pain in the ears, which is like having bradawls bored into them, and is sometimes very acute, ceases." The late diving inspector of Her Majesty's ship *Excellent* remarks: "the only part of the body in which the rush of blood was felt painfully was the head, and that I believe was from the gradual compression of the air in the dress as the diver lowered himself in the water; the sensation depends greatly on the manner of the man's descent; if he go slowly down, descending at intervals a trifling distance, he greatly diminishes the pressure, and so *vice versa*". Mr. G. C. has been fourteen years a diver, five and a half years of which he has passed in training divers for the navy. The first time he went under water, he felt a very severe pain in the ear, but no longer noticed it after a little time, until he became immersed in deep water, when it again returned to some slight extent, but disappeared on his reaching the bottom in eighteen fathoms or at a depth of 108 feet. He was then, he writes, "quite comfortable". Mr. J. H. has been diving for nearly thirty years. During the whole of that period, he has had almost daily practice, and has been down under water from one to four hours at a time, and at depths varying from five to eighteen fathoms. He remarks that the greatest pressure in descending to great depths is felt under the armpits (crutch), where a sensation is perceived as if a knife were entering the body at that part. When troubled with a cold, the drums of his ears have been stopped, and, while descending, his head has experienced a sensation which he compares to its being pierced through. When suffering from slight rheumatism, he has felt as if his flesh were being torn to pieces.

Life can, therefore, be carried on with comparative comfort, when in health, for a period of from one to four hours, at a depth of about 108 feet, and work under such circumstances can be done, necessitating considerable muscular exercise, such as unloading a sunken ship. The return journey to the surface is, however, always, apparently, attended with more or less discomfort. Mr. J. H., with his experience of nearly thirty-one years, writes, "On returning to the surface, blood invariably rushes to the head". During the whole of his career, he had never bled

at the nose or ears, but has seen instances of men coming to the surface bleeding from those parts, though from nowhere else. Mr. A. C. "has never known an instance of a diver bleeding from anywhere but the nose, mouth, or ears", and then only through fright or exhaustion. Mr. G. C. has seen instances of men coming up bleeding at the nose and ears. He thinks that must be through weakness, for they were in shallow water, and only about one hour down. With respect to the influence of the state of health of divers on their sensations under water, some very interesting particulars are contained in Mr. A. C.'s letter. He observes: "the general symptoms are, in my opinion, to be gathered from the man's own state of health, or habits; if he is given to drink, then you may expect an accident, or sudden death, at any time; or, if he is consumptive, or his chest the least affected, the air is not sufficiently pure for him. During the latter part of my time as instructor in the *Excellent*, I had been suffering from chest disease; and the last time I was down I could not remain five minutes, as the air was not pure enough for me to breathe." Mr. G. C., when having a slight cold, felt hot flashes all over his body, and a pricking sensation. Now, if a column of thirty-three feet and ten inches of water exert a pressure of about 15 lbs. on the square inch, at a depth of 108 feet, the pressure will be equal to about 47.9 lbs. on the square inch: a man of a height of 5 ft. 8 in., the surface of whose body would be equal to from 2,325 to 3,100 square inches, would therefore, at the depth of 108 feet, support a pressure of water of from 111,367 to 148,490 lbs. At the seaside, the atmospheric pressure on such a person would amount to from 34,875 to 46,500 lbs. He would, therefore, while at a depth of 108 feet from water, be subjected to a pressure of from 76,492 lbs. to 113,615 lbs. in addition to the weight he had to bear from the atmosphere at the seaside. On coming to the surface, this enormous excess of pressure is got rid of; no wonder a sensation should be felt of rushing of blood to the head, and that sometimes hæmorrhage should follow. The most remarkable feature of immersion in deep water is, perhaps, the fact that respiration should be carried on, apparently without difficulty, under such pressure; and it is natural enough that, should the diver have anything the matter with his lungs, his respiration should be seriously interfered with; in such cases he becomes liable to be poisoned by his own carbonic acid, as the blood must find it very difficult under such a pressure, and especially when the lungs are not in a perfect state of health, to emit the carbonic acid it contains; the air is not too impure for the diver to breathe, but his blood becomes impure from its retaining its own carbonic acid. The phenomenon is precisely the same as when increased pressure is brought to bear on boiling water; the boiling instantly stops, and steam ceases to be evolved.

Now, the difference of pressure of the atmosphere on the human body at the seaside and top of Mont Blanc amounts to about 15.432 lbs., being reduced by nearly one-half; and we can readily imagine the greater freedom with which carbonic acid will part with the blood in the lungs at such an elevation. It is really impossible to refrain from sharing Dr. Lombard's feeling of wonder that the body should be able to adapt itself to such extremes of external physical conditions.

An apology is due on my part for having gone so far astray of the subject, as stated in the heading of this communication. I have thought the above physiological considerations, which are not unconnected with my subject, of sufficient interest to warrant my calling the reader's attention to them on the present occasion.

TREATMENT OF CHOREA BY ARSENIC IN LARGE DOSES.

ARSENIC has long been regarded as a useful therapeutic agent in the treatment of chorea, but it may not be generally known that the curative value of the drug is greatly increased by administering it in full doses. The tolerance of children for arsenic is a matter of common observation, and this tolerance is especially marked in the case of a non-febrile disease, such as chorea, where there is no increased irritability of the digestive organs. To a child between the ages of five or six and twelve, the subject of this complaint, Fowler's solution may be given in doses of ten minims three times a day, directly after meals. The influence of this treatment upon the disorder is seen almost immediately, and it is rare for any of the physiological effects of the drug to be observed. By this means, cases of the disease which had resisted smaller doses of arsenic may be cured in a few days, and even severe cases seldom last longer than a fortnight or three weeks.

EUSTACE SMITH, M.D., F.R.C.P.

DIPHTHERITIC PARALYSIS:

ITS NATURAL COURSE, PATHOLOGY, TREATMENT, AND RELATION TO PARALYTIC AFFECTIONS FOLLOWING FEVERS.*

BY SIR JOHN ROSE CORMACK,

Chevalier of the Legion of Honour; M.D. Edin. and Paris; F.R.S.E.; Fellow of the Royal Colleges of Physicians of London and Edinburgh; Physician to the Hertford British Hospital, Paris; etc.

[Continued from page 156.]

In recording this case, I have but slightly abridged the original bed-side reports, believing that complete histories of complex cases are fully observed from first to last are most appreciated by clinical students. Moreover, abstracts are not only historically imperfect, but they are apt to be biased statements, from the narrator unintentionally giving undue prominence to the facts which most support his own particular views. A desire to avoid this evil, and to allow readers to form their own conclusions from complete data, is my reason for having detailed some cases at great length. Having, however, occupied so much space with minute clinical histories, I must (leaving for the present some additional illustrations of the relations of paralysis to enteric fever, to the puerperal state,† and to hysteria) proceed briefly to illustrate the relations of paralysis to cholera, dysentery, and small-pox.

PARALYSIS DURING AND AFTER CHOLERA.

There is an excellent paper on temporary glycosuria by Mr. William Sedgwick, in the *Medico-Chirurgical Transactions*, founded on observations which tend to prove that there had existed paralysis of the abdominal sympathetic nerve prior to the glycosuria, and that the occurrence of the latter would serve to show that, during reaction from previous collapse, there is "a temporary excess of restorative effort".

It is well known that patients convalescent from cholera, in common with persons recovering from various diseases, often require the catheter to be used, in consequence of temporary paralysis of the bladder. Dr. Sutton has noted (page 412 of *Simon's Ninth Report to the Privy Council*, 1867), that "in more than one case four or five pints of urine were drawn off in twenty-four hours". He gives in detail the case of a woman, aged 39 years, whose husband and three children died in the East London Cholera Hospital from the disease. The woman was attacked with cholera at 2 A.M. on October 6th, 1866, and was admitted to the hospital at 7 A.M. on the same day. After a residence of nineteen days, she was dismissed in full convalescence. It is specially stated, in the history of this case, that, at 3 A.M. on October 16th, three pints, and on the 17th a similar quantity of urine was drawn off.

Dr. Henri Jaubert, in his thesis (Paris, 1866), *De la Convalescence du Cholera*, states that he had had the opportunity of observing 888 patients of both sexes and of all ages in a temporary asylum established for the reception of convalescents from cholera. Under the heading, "Accidents Nerveux", he gives three classes of cases: viz.: 1. Cases of cramps of limbs; 2. Cases of contractions of the extremities; 3. Cases of different forms of paralysis. In this last division, after referring to the observations of Dr. Me-net (*Archives Générales de Médecine*, Fév. et Mars, 1866), he relates the case of a man, aged 60, who, during the course of the malady, was all at once attacked with weakness (*faiblesse*) in the entire right side of the body, including the face. When the patient was first seen by Dr. Jaubert, the right naso-labial sulcus was slightly obliterated, the commissure was depressed, and the tongue deviated slightly towards the right. It was with the utmost difficulty that he could make any use of the right arm and leg. He was, however, able to stand, and, with the assistance of a crutch, he could take some steps. He walked like a mower, advancing one foot before the other. There was inertia of the bladder (*crise parassense*). After eight days' residence, the patient left the Convalescent Home in the state now described. It is to be regretted that this case remained under observation for so short a period.

Dr. Jaubert mentions another case of hemiplegia following cholera, which he had seen, but of which he did not take notes. In this case, the paralysis suddenly manifested itself at the commencement of reaction.

Dr. Jaubert likewise mentions having seen two cases of incomplete paralysis of motion and sensation. The subject of the first of these cases was a male patient in the Convalescent Home. When admitted, there existed nearly complete insensibility of the little finger and ring-

* Partly read before the Medical Section at the Annual Meeting of the British Medical Association in Norwich, August 1874.

† The best clinical account of this subject is that given by Dr. Fleetwood Churchill of Dublin. It constitutes the seventeenth chapter of the fifth edition of his work on the *Diseases of Women*, and is entitled Paralysis occurring during Gestation and in Childbed.

fingers, and of the inner half of the middle finger; the prick of a pin was not felt unless a deep thrust were made. The gentle friction of the arm with anything was not perceived by the patient. The anæsthesia extended up to the elbow, but it was less in degree in proportion to the nearness of the situation to the elbow: it was limited to the cubital half of the arm. In the right foot, the two outer toes and the external half of the third were similarly affected. In the left foot, the affection was limited to the great toe. The paralysis did not extend to the leg on either side. The motor power was modified in a similar manner to the sensation. The patient could neither flex nor extend the affected fingers and toes. The paralysed parts were the seat of an unpleasant formication. This case was under observation during only a part of its course. The history concludes with the statement that, when the patient left the Convalescent Home at his own request, he was more paralysed than on admission. In the other case, there was no loss of motor power; and the anæsthesia was limited to the distal half of the ring-finger and little finger of both hands.

Magendie, in his *Leçons sur le Choléra*, published at Paris in 1832, refers to paralysis as a sequel of cholera. He says that the way in which it begins to manifest itself is generally so gentle, that the patients seem to experience only extreme debility and a dislike for food. In about eight days, he says they pass into a state of profound prostration; the muscles of the face are paralysed, and those of the limbs become quite flaccid. The mental powers grow torpid, and at last death takes place, with a general destruction of all the vital powers.

The epidemics of 1849 and following years furnished numerous cases in which paralysis was secondary to cholera. Gubler refers to a series of lectures delivered in 1849 at the Bicêtre by Dr. Delasiauve, upon cases in which attacks of cholera had been followed by mental alienation and paralysis.

Dr. O. Landry, in his work *Sur les Causes et les Indications Curatives des Maladies Nerveuses*, states that, during the cholera epidemic of 1849, a man suffering from a formidable attack of the disease was admitted, under the care of Piedagnel, to the hospital of La Pitié at Paris. During convalescence, paralysis ere long invaded the superior and inferior extremities, without the occurrence of any symptoms of the nervous centres being involved. Micturition and defecation continued to be performed in a normal manner. The muscles became atrophied. Treatment having proved unavailing, the patient was transferred to the Bicêtre as an incurable.

Briguet and Mignot, in their *Traité du Choléra Morbus*, published at Paris in 1850, mention three cases which occurred during the epidemic of 1849, in which partial paralysis manifested itself in convalescence from cholera. In one of these cases, the paralysis was limited to the hands. In the two other cases, the superior and inferior extremities were affected: in both cases, the paralysis first showed itself in the superior extremities. In the three cases, recovery from the paralysis took place. As Gubler remarks, in referring to these cases, it is noteworthy that restoration of power commenced in the hands, and that the paralysis remained longest in the feet and legs—noteworthy, because the same order in recovery is observed in the paralysis consecutive upon diphtheria and other acute diseases.

PARALYSIS DURING AND AFTER DYSENTERY.

Dysentery has sequelæ similar to cholera in respect of sensation and motion.

On the 22nd April, 1872, I was telegraphed for to meet in consultation Dr. Bazard at Dijon, in the case of an English gentleman, who was laid up at an hotel in that town, unable to proceed on his homeward journey from Egypt to London. I reached the bedside of the patient between five and six o'clock on the afternoon of the 22nd. He had, I was told—excepting occasional remissions lasting for a day or two—been severely suffering for some weeks from dysentery. During the whole of that period, he had been travelling homewards by short stages, suiting his journeys as much as possible to his ebbing strength. His paramount idea had evidently been to get home to obtain efficient treatment; for he had only casually consulted physicians on the way, and had never placed himself under serious treatment till his arrival at Dijon, when it was too late. At the date of my visit, the sanguineous alvine flux had entirely ceased, there remaining, however, a very irritable state of the intestine, manifested by diarrhoeal stools quickly following the reception of food into the stomach, if more than two or three tablespoonfuls of beef-tea, breadberry, or thin arrowroot gruel were taken. The cessation of the dysenteric flux had not, however, been followed by any restoration of strength or any other sign of real amendment. On the contrary, the debility had alarmingly increased during the preceding two days, and within that period there had also supervened, or at least there had been first observed, inertia of the bladder and partial paralysis, with

anæsthesia of the lower extremities. When I arrived, there was anæsthesia and incomplete motor paralysis of both legs. There was no impairment of the motor or sensory power of the superior extremities, or of the muscles of the face, tongue, or œsophagus. The intelligence was not affected. The urine was scanty and slightly albuminous. The pulse was about 90, weak, and intermittent. My questions were answered fully and clearly. I passed the night in an adjoining room. The door between the two rooms being ajar, I heard all that passed. He spoke to the nurse at intervals in a distinct voice, and took beef-tea, arrowroot, and wine, when they were offered, at short intervals. I was twice summoned to his aid during the night, in consequence of his being attacked by dyspnoea. On both occasions, he obtained considerable relief from the application of large thin poultices of linseed-meal and mustard to the thoracic parietes. When I left early in the morning for Paris, he had just awoke from a short sleep. He concurred with me and Dr. Bazard in thinking that he was in a rather better state than on the previous day. On arriving at my house in Paris, I received a telegram, dated noon, requesting me to return to Dijon. I had made my arrangements to do so, when another telegram, dated 3 P.M., informed me that he had just expired. I afterwards learned that his death, till within an hour of its occurrence, did not appear imminent. It seemed (as I afterwards learned) to have been caused by profound general prostration and paralysis of the respiratory muscles. Death was not preceded by delirium.

Recently, I was consulted by a military officer passing through Paris, on his way home from India on sick leave. He had suffered severely from dysentery, followed by debility and a great loss of power in both inferior extremities, which, he said, at one time amounted to complete paralysis. When I saw him, he could walk with the aid of a staff. He had a very anæmic appearance, and was suffering much from constipation. He was taking citrate of iron and quinine, which I recommended him to continue, with the addition of a dinner aperient pill, containing a grain of the extract of *nux vomica*. I saw this patient only twice, and have had no opportunity of knowing anything of the course of his malady subsequently to my last interview with him.

Zimmermann says that, in some persons who have had severe attacks of dysentery, it is not unusual in convalescence to meet with paralysis of the mouth and tongue, and sometimes of the whole of the lower part of the body. Sometimes, he says, universal paralysis manifests itself simultaneously with the cessation of the dysentery. He does not describe any individual cases. (*Traité de la Dysentérie*: traduction Française, p. 13. Lausanne: 1794.)

I have had several patients under my care for paralysis of the rectum, who traced that affection back to severe dysenteric attacks of old date.

The frequent occurrence of intractable inertia and paralysis of the rectum after dysentery has led some authors to attribute this inertia and paralysis to dysenteric lesions of the intestinal canal. A fact of kindred character is noteworthy in the present inquiry; viz., that paralysis following dysentery attacks the inferior more frequently than the superior extremities. As a rule, in paralysis of cerebral origin, the superior extremities suffer most severely and far more frequently.

[To be continued.]

FOUR CASES OF A PECULIAR EPILEPTIFORM DISEASE.

WITH SYMPTOMS INDICATIVE OF SPECIAL IRRITATION OF THE NERVE-CENTRE OF ARTICULATE SPEECH.

By W. B. CHEADLE, M.D., F.R.C.P.,
Senior Assistant-Physician to, and Lecturer on Pathology at, St. Mary's Hospital;
Assistant-Physician to the Hospital for Sick Children.*

THE cases here recorded exhibit epileptiform disease in one of its rarer and most curious forms. Trousseau has described seizures of an analogous kind in his *Clinique Médicale* as varieties of epileptic vertigo. As in Trousseau's cases, so in these, there is something more than the mere transient giddiness of the ordinary *petit mal*; something less than, and different in character from, the full epileptic fit. They have one distinct feature in common, although it is not equally prominent in all; viz., rapid muttering, the frequent hurried repetition of the same word or phrase during the convulsion; so that this special variety might, perhaps, be designated "clampsia loquax," or "muttering epilepsy".

CASE I.—Albert H., aged 18, draper's shopman, first came under the care of Dr. Cheadle at St. Mary's Hospital in March 1868, suffer-

* The cases are reported by Mr. G. C. A. Moir.

ing from a peculiar form of epileptiform attack, to which he had been subject since he was six or seven years of age. At that time, he had an attack of chorea, and, about the same period, he received a severe blow on the head with a heavy stick, about the centre of the coronal suture, which left a small well marked scar. He could not state positively whether he had any fits between the time he had chorea and his surviving the blow, but thought there were none till after the chorea. At the time of his admission, he had sometimes two fits a day, and then was free for a time, and generally he had two or three at the first onset, followed by a week's freedom from them. The series decreased in strength gradually, the last being only a sensation. During a fit, he felt frightened; desired to lean against some support; he trembled; was unconscious, but never fell, having sufficient warning to enable him to place himself safely. The attacks commenced with a peculiar sensation in the head. He then lost the use of the left arm, not of the right, although he dropped anything he might have been holding with that hand at the time. His eyes were said to be open, and to roll about, and he talked incessantly while the attack lasted, repeating the same word or phrase very rapidly over and over again. He had never hurt himself or bitten his tongue, but had twice passed urine unconsciously during the fit; he thought his bladder was very full at the time. After the fit, he was very drowsy. There was no history of nervous disorder in any other member of the family. This patient remained under treatment, with some short intermissions, for upwards of three years, and on one occasion was seized with one of his attacks while in the consulting-room, when the phenomena were carefully observed and noted down by Dr. Cheadle. Whilst he was standing waiting for his turn to be seen, the boy's face became suddenly distorted; he trembled, and looked frightened; his eyes became fixed and turned upwards, and he fell gently back against the wall, close to which he was standing. As he stood leaning thus supported, with his head slightly drawn back and his face turned upwards, he kept muttering with extreme rapidity, over and over again, the same words: "Man of war", "man of war", "man of war", about a dozen times. Then his features relaxed, and he stood up quite himself again. He was clearly perfectly unconscious during the height of the seizure; but, when sharply spoken to as it was passing off, he made an effort to reply, and evidently heard what was said to him. The whole attack did not last more than a minute. He was conscious afterwards that he had had an attack, but could not recollect what he said or did while it lasted. During the time of his long attendance, he was treated with bromide of potassium, belladonna, and strychnia; and on one occasion with the bromide and iodide of potassium together; but he never seemed to obtain other than temporary benefit. The bromide was used in doses varying from twelve to twenty grains three times a day, and always controlled the fits so far as to reduce their frequency and severity. On the occasion when it was prescribed with the iodide, no increased benefit was apparent from the combination. Belladonna was prescribed in the form of extract, of which a pill, varying from half a grain to a grain as a dose, was ordered every night. This also gave relief, either when used alone, or taken in conjunction with the bromide of potassium. Strychnia was given in the form of liquor strychnie in doses of five minims three times a day; it was tried for twenty-eight days, but the fits increased in number and severity, and it was abandoned. The patient felt so much relieved by the belladonna and bromide, that he continued his attendance for years, although he lived a considerable distance from the hospital.

CASE 11.—Miss A. W., aged 13, came under the care of Dr. Cheadle on September 22nd, 1873, suffering since her fourth year from attacks of slight loss of consciousness, lasting a few seconds or even minutes. During the attack, her eyes were drawn, she moved her body and head to and fro slowly, and spoke incoherently, generally of Scriptural subjects, repeating the same word or phrase over and over again, such as the name Moses or Jacob. She had never been hysterical. The only severe attack she ever had took place in the February or March previous to her coming under observation, and was like one of her ordinary seizures, only prolonged; in it she muttered, but neither foamed at the mouth nor struggled much. She had one or more attacks daily, and had twelve attacks on the day previous to coming under observation. Her mother has one other child, who has become strange and imbecile. Her maternal aunt was insane. No further family history could be obtained. The patient was said to have ascarides. A vermifuge of santonin and calomel was ordered, together with a mixture containing bromide of potassium in scruple doses, and iodide of potassium in doses of two grains, with cinchona and quassia. She took the powder on the 23rd, and had twenty fits: on the 24th, twenty-two fits; but, on the 26th, she passed a round worm, and had only two fits. On the 29th, she again had santonin with compound scammony powder. On October 6th, the powder was

reported to have acted freely, but no worms came away. She had two slight fits, which lasted just an instant, when she turned up her eyes and muttered a few words. From this time, the patient improved; had no more attacks, except once or twice very slight vertigo, the medicine being gradually reduced and left off altogether in December. From this time to May 1874, she had only three slight fits at long intervals. The bromide was resumed in twenty-grain doses, and no relapse has occurred up to the present time, December 1874.

CASE 111.—Miss K. F., aged 11, came under Dr. Cheadle's care on June 3rd, 1874, on account of slight vertiginous attacks, to which she had been subject for nine years. She was a quick excitable child; has never had rheumatism, chorea, or worms. She had an attack of convulsions when teething. There was no epilepsy or insanity known in the family. She was the youngest of eleven children, who were all alive and healthy. The attacks of vertigo were always ushered in by severe pain in the abdomen, about the umbilical region. She then put her hands up to her head, pulled down her hair, and held her ears, evidently in a state of confused half-consciousness, and repeated with great rapidity many times a phrase or sentence; often "Shut the door, shut the door, shut the door", many times over. Her face then became very blue, and she made a choking sound in her throat. The pupils of her eyes dilated, and a dreamy look passed over her face. Then she cried out, "All right, all right; I shall be better directly", as consciousness returned. She did not fall down, but she knew when an attack was coming on, and took care. She muttered and called out in this rapid incoherent way wherever she was. Attacks had taken place in church, and she cried out in this way. After the attack, she was very drowsy, and often went to sleep. The fits occurred sometimes three or four times a day; sometimes she was free for weeks. Excitement of any kind was very liable to bring on an attack. On examination, the chest was found normal, the heart's sounds clear, except slight prolongation of the systole at the apex. The abdomen was natural in appearance; no tumour of any kind could be detected, and there was not the least tenderness at any point. She was ordered five grains of santonin at night, followed by ten grains of compound scammony powder the next morning, and fifteen grains of bromide of potassium three times a day. For two days after taking the powders, she suffered great pain in the abdomen, so severe as to make her cry out and roll about, and also repeated attacks of the talking convulsion, five or six during the day and several during the night. The bromide of potassium was now increased to twenty-three grains, with three grains of iodide of potassium and one-eighth of a grain of extract of belladonna. The following week, the mother reported that the child had a bilious attack and diarrhoea, and the medicine was suspended. The attacks have continued, but no opportunity has occurred for the resumption of regular treatment.

CASE IV.—Louisa G. came under Dr. Cheadle's care in March 1872, having suffered for twelve months from attacks of convulsion of a curious character. The attacks were described as follows. She turned dark in the face; her eyes became fixed, and she seemed unconscious; her arms and legs "worked", and sometimes she fell; but the most constant feature was the pulling of her clothes up to her neck, crouching on the floor with her hands up to her chin; sometimes kicking, scratching, and laying hold of things; sometimes she talked rapidly, repeating the same phrase, often counting one, two, three, over and over again. She had no sobbing or crying after the fits; was drowsy and stupid, but did not sleep. She was conscious of having had an attack, but had no recollection of what she said or did during it. During the last week, she had had three or four of these fits daily, with one day's intermission. They were becoming more frequent and more severe than they used to be. She had several convulsions in infancy when teething. A careful physical examination disclosed nothing abnormal. She was not known to have worms. Her tongue was clean, the bowels reported regular, and appetite good. Four grains of santonine were ordered at night, and ten grains of compound scammony powder the next morning. Twenty grains of bromide of potassium in two drachms of steel wine were given three times a day. When seen a week later, she had had a fit every other day, and four on one day. The bromide was increased to thirty grains three times a day, and from this time she remained absolutely free from all attacks, except slight "warnings", in the shape of giddiness, speedily passing off. The medicine was gradually reduced, with the apparent effect of leading to a recurrence of the "warning" symptoms, but no decided attack. Thus she continued until March 26th, 1874, i.e., two years after the commencement of systematic treatment, never having an attack of talking and struggling convulsion, but occasionally slight vertigo. She had left off medicine for long intervals—weeks at a time—resuming it only when threatened by a return of the warning symptoms.

In all these cases, the subjects were young. I have not met with an

example of epilepsy of this form in adults, although many of Troussat's cases of an analogous disorder occurred in grown persons. In the present group, the disease commenced in every instance in childhood: in the first case, at 6 or 7 years of age; in the second, at the fourth year; in the third, at 2 years old; in the fourth, at 7.

In two cases, the children had suffered from convulsions in infancy; and in one, which recovered, there was a history of insanity and imbecility in the family. In the first case, the seizures were attributed to a severe blow on the head; in the second, they were no doubt aggravated, but probably not originally caused, by the presence of a round worm, the symptoms abating after its expulsion, but not ceasing entirely for many months. In the remaining cases, no cause could be assigned. In one of them, the existence of an aura, or at least of a premonitory paroxysm of pain in the abdominal region, seemed to point to some local irritation there as the starting-point. The rapid repetition of the same word or phrase, evidently a mere automatic discharge of language not springing from ideas, points to the morbid stimulation of that portion of the brain which has been shown to be intimately connected with the translation of ideas into articulate speech; viz., the third left frontal convulsion. The morbid anatomy of aphasia, and the striking experiments made by Dr. Ferrier, who says that he has succeeded by the electrical stimulation of this same third left frontal convulsion in producing cries in animals while in a state of unconsciousness, give special interest to the cases here recorded. The phenomena of phonation produced during the epileptiform convulsion are so closely analogous to those produced in the experiments on animals, as to lead to the belief that the same portion of the cerebrum was irritated by morbid influences in the one case as by the electric stimulus in the other. Against this there is, however, the fact, that in Case I the convulsion was accompanied by loss of power in the *left* arm; yet on the other hand, cases of left hemiplegia with aphasia have been recorded, and the active organ of speech is probably not invariably on the left side of the cerebrum. In these instances of disease, the stimulus may have been applied directly to the centre, or, as was probably the condition in Cases II and III, reflected from some distant organ.

In Cases II and IV, continued use of the bromide of potassium resulted in the complete disappearance of the symptoms, which there is every reason to hope will be permanent. In one of these, the disease had existed for nine years. In Case I, the symptoms were mitigated by the use of the same drug; but complete relief was not obtained. It should be remarked, however, that in this instance the largest dose administered was twenty grains—an amount which subsequent experience has taught me is quite inadequate for the complete control of epileptiform attacks at the age of the patient in question; viz., 18. In Case IV, the occurrence of an intercurrent affection has prevented the proper trial of the bromide of potassium, and it has not yet been resumed.

PUERPERAL FEVER IN PRIVATE PRACTICE.

By WILLIAM HINDS, M.D., etc.,
Professor of Botany, Queen's College, Birmingham.

THE editor of this JOURNAL invites a contribution from the individual experience of its readers, otherwise a very limited experience would scarcely justify any such contribution from me. Besides some recent cases, of which I will speak, my previous experience is confined to one fatal case. This was the 103rd case of midwifery which I attended, and I had no more puerperal fever until I had attended some 550 cases in addition. This first case occurred in 1847, and was followed by death in seven days. My last case occurred in January last in a primipara. I will give some account of both these cases, and do what I can to trace the etiology in each. The first case stands alone in my experience, and, as the last one is typical of some others, none of which proved fatal, I will give a few notes of that case only.

CASE I.—Mrs. P., aged 38, of active sanguine temperament, began to experience labour-pains about 5 o'clock on February 12th, 1847, which gradually increased in strength and frequency until 9 the same evening, when I was summoned to attend her. The pains on my arrival were active, and belonged to the first stage of labour. The os uteri was not dilated or disposed to dilate. It was marked by firm cicatrices, most likely the result of injuries at former labours. After several hours, the os somewhat improved; but the pains all at once ceased, and not a single pain came on for an hour or two. There was neither exhaustion nor fever, and the patient was perfectly calm. After an hour or two, the pains recurred, and were as active as before, and the os uteri became more dilated and its edges soft and elastic; but the pains in a few hours again ceased entirely. There was, however, not the least exhaustion, and nothing to induce active interference. The

same thing had occurred in her labours previously, she said; and her medical attendant had to leave her three successive times, and she had never required any instrumental aid. A third time I was compelled to witness a cessation of pains, and this time there was some disturbance of the circulation. The pulse was 120, the tongue was coated, and some thirst and considerable exhaustion. Ergot had been previously administered, and the head, which presented in the first position, rested on the perineum. This was about twenty-four hours from the commencement of labour, and near six from the commencement of the second stage. I ordered an enema to be administered, and left to fetch my forceps and summon a medical friend near. Returning very soon, I found she had been delivered immediately after my departure. The placenta had also been removed by a woman of some experience, who had been in attendance. The placenta, on examination, appeared to be perfect, and the uterus well contracted. During the first night, she had not much sleep; was restless and thirsty, and the tongue still coated when seen on the 13th.—February 14th. Pulse, 120; skin hot and perspiring; thirst and restlessness. A pill, with one grain and a half of opium, was ordered to be taken at bedtime.—February 15th. She had an excellent night's sleep, but the thirst was still great and the tongue coated; pulse, 120. The patient expressed herself much better. There was no milk at present. She made no complaint, except of thirst. A brisk aperient and nutritious diet were ordered.—February 16th. She had been restless during the whole of the previous night; the bowels were well open yesterday. There were thirst and coated tongue, and occasional delirium. She now complained of erratic pains in the limbs, which she considered rheumatic. There was some milk. The pulse was 120 at least, and more feeble. The skin was dry, not moist as before. There was not the slightest tenderness of the abdomen. I ordered a diaphoretic mixture, with ammonia and opium, to procure sleep.—February 18th. She had little or no sleep during the last three nights, although an opiate was administered. She was delirious at intervals, and last night she was with difficulty restrained from getting out of bed. There was no pain of head, and no abdominal tenderness. Nausea occurred occasionally; the tongue was furred and brown near the tip. Pulse, 135, weaker. She was ordered to have wine; to take castor-oil immediately, and two grains of opium at bedtime.—February 19th. She had eight hours' sleep, which was, however, much disturbed. She complained of pain in the arms. On the outer part of each forearm, there was a slight blush of redness and some oedema. The lower extremities seemed free from redness. There was some nausea; no tenderness of the abdomen. The bowels were relaxed five or six times; the tongue was brown, the pulse weaker, and the breathing had become hurried and laborious. There was no milk, and the breasts had become quite flaccid. The lochia were scanty, and somewhat offensive. Wine was ordered to the extent of two ounces every two hours, and quinine every four hours. In the evening, the red blush on the forearms occupied the whole outside space from wrist to elbow, and had become deeper, and the oedema had somewhat increased. The breathing was still laboured, and the pulse was 140 and tremulous. She had diarrhoea. The tongue was brown and dry. She was ordered wine and egg-flip *ad libitum*. The patient died early on the following morning. No *post mortem* examination was obtained.

REMARKS.—Here was a case of undoubted blood-poisoning; but what was its advent, what its etiology? At that period, there was an almost universal belief in contagion or zymotic infection. In this direction, I made most careful inquiry, and I certainly found that the female who was left with my patient, who removed the placenta in my absence, and who was employed by various medical men to give injections, etc., had, according to her own statement afterwards, been in attendance within a few days previously upon cases of both erysipelas and scarlatina. Did she communicate to my patient any zymotic poison? With the light I then had, I supposed this rather probable. I do not think so now. I am decidedly of opinion that it was a case of septic infection. Small escapes of blood, intrauterine, and confined during many hours of a protracted labour, will certainly suffice to produce a septic poison; and, in this case, the cracks in the hardened cicatrices of the os uteri would easily facilitate the process of septic infection. In this way, I have come to regard this case as one of primary sepsis, caused by breach of surface.

My second case, which I shall give very briefly, belongs to a totally different category. Here the uterus alone, and secondarily the abdominal parts in its immediate vicinity, were first affected.

CASE II.—Mrs. W., primipara, was confined on January 27th last, after a labour of about ten hours' duration. She progressed favourably for four days at least; for, when seen on February 1st, there was no complaint, except of restlessness and insufficient sleep. On the fifth day, on entering the room, an extremely unpleasant earthy odour was

found to pervade the atmosphere. I immediately inquired the meaning of this, but, before any answer could be given. I lifted the bed-clothes partly from the patient, when an intolerable stench escaped from the bed. The patient had had a frightfully putrescent and offensive discharge, and, for two or three days at least, had not been properly cleansed and changed. Rigors, very severe, had occurred, with sleeplessness. There was considerable prostration, with an anxious, flushed, and pinched countenance, with acceleration of pulse. The abdomen over the uterine region was very tender to the touch. There were some other grave features in the case, which made me regard it as one of great danger. Immediate steps were taken to wash out the vagina and uterus with lukewarm soapsuds impregnated with solution of soda chlorinata, and the processes to be repeated over and over again. Immediate and complete cleanliness was enjoined, and the napkins ordered to be well sprinkled with the same diluted chlorine solution. Opium and calomel were administered every eight hours at first, and counterirritation and fomentations were ordered to the abdomen. The next day, there was some improvement, and the patient afterwards gradually and fully recovered.

REMARKS.—In this case, too, there was some blood-poisoning no doubt, but it was indirect, or arose from the absorption of poisonous or septic gases, while in the previous case, I have no doubt, the blood was poisoned by the direct and immediate absorption of a liquid poison. In the last case, death would soon have occurred from uterine and general peritonitis, if from nothing else, had not immediate means been taken to alter the conditions present in the cavity of the uterus. The diagnosis in the first case could be of little avail as to the result, and the prognosis grave in the extreme. In the second case, there was much more room for remedial measures, and, with the proper remedies energetically applied, and with perseverance, there was good room for success. I fear to encroach too much upon the space of the JOURNAL, but should like to be permitted to remark on one or two points brought out in the very valuable discussion on this subject, and the kindred subject of pyæmia, as recorded in the columns of the JOURNAL. The second of the cases I have given, and those belonging to the same category, certainly, as far as they go, have some bearing on Mr. Wells's second double proposition, and also somewhat illustrate the negative of the third. A good deal has been said of the relation of bacteria to puerperal and other cases of a certain phase, and no doubt this relation, in a strictly scientific sense, is of very great interest indeed; but I much question its practical value in reference to either curative or preventive measures. It is, I think, to be inferred that an extraordinary susceptibility of puerperal cases to the onslaught of zymotic poisons in general is not to be too hastily assumed. If any general predisposition to attacks from this class of causes exist, it can, I believe, arise only from the lowered vitality incident upon the puerperal state. No doubt, a lying-in-woman who, previous to her confinement, is susceptible, would become more so when her powers of resistance were lowered by childbirth. At the same time there would appear, from my own experience, good ground to believe that many women, in the puerperal state, are not susceptible at all to either scarlatina or small-pox, or to any other disease of the same class. Scores of times I have attended cases of small-pox and others of the zymotic class, and visited lying-in cases during the same morning circuit. Sometimes, it is true, I have been able to take the precaution to visit the puerperal cases before the others, but not always, and no one case of infection, to my knowledge, has ever taken place with me.

CLINICAL MEMORANDA.

THE MEANING OF THE TERMS "CROUP AND DIPHTHERIA".

IN a paper on the above subject, in the last number of the JOURNAL, Sir John Rose Cormack states that "the spasmodic croup of English authors is the *faux* croup of the French". I have always believed, and I believe still, that the spasmodic croup of English authors is also the spasmodic croup of the French; its synonyms being "Laryngismus stridulus", "Crowing inspiration", "Thymic asthma". The *faux* croup of the French is the "Inflammatory croup" of English authors. The French synonym is "Laryngite striduleuse", stridulous laryngitis; the cough and the respiration being, as a rule, more stridulous in cases of inflammatory or false croup without false membranes, than in cases of so-called "true croup", with diphtheritic false membranes in the larynx and trachea. It appears to me that to speak of the spasmodic croup of the English as synonymous with the false croup of French writers, is to introduce a new element of confusion into the discussion of the relations between croup and diphtheria. There are three distinct

diseases to which the term croup has been applied generically: 1. Spasmodic croup, *syn.*, laryngismus stridulus; crowding inspiration; child-crowing; thymic asthma. 2. Inflammatory croup, *syn.*, stridulous laryngitis; catarrhal laryngitis; false croup. 3. Diphtheritic croup, *syn.*, laryngeal diphtheria; membranous laryngitis; membranous croup; true croup. Of course, laryngeal spasm may occur as complication of either simple inflammatory croup or of diphtheritic croup.

GEORGE JOHNSON, M.D., F.R.S.,
Physician to King's College Hospital.

THE TREATMENT OF ACUTE PERITONITIS IN OVARIAN DISEASE.

THE alleviation of the intense pain which occurs in cases of peritonitis, secondary to previous pathological changes in the peritoneal cavity, is frequently a matter of considerable difficulty. For example, where cancerous deposits exist in the mesenteric membranes, or in the various forms of ovarian disease, the recurrence of peritonitis and its duration appear to be attended with more acute suffering than any form of disease with which we are acquainted. The result of *post mortem* examination in such cases generally enables us to ascertain the fact, that active organic changes have apparently occurred in some particular part of the diseased tissues, from which the peritoneal inflammation has originated. In a case recently under my care in St. George's Hospital, where the symptoms and physical signs led to the diagnosis of an ovarian tumour of considerable size in the left pelvic and abdominal regions, composed of one cyst with walls of some thickness, and attached by strong and dense adhesions to the surface of the uterus and pelvis, the symptoms to which I have above referred suddenly occurred in that severe form which is met with in the worst cases of puerperal peritonitis. The abdomen was distended, tympanitic, and excessively painful; and the constitutional disturbance such as to lead us to expect that the patient would not survive many hours. With the view of relieving her from the pain she was enduring, I punctured the peritoneal cavity with a fine cannula trocar, and allowed the fetid gas to escape. The trocar was again introduced and passed into the cyst, the surface of which reached between two and three inches above the pelvic brim. By means of the aspirator, about a pint and a half of fetid pus was drawn off, and the cyst injected with warm carbolised water (1 in 50 at temperature 98 deg.) By alternate injection and aspiration, till the fluid was free from odour and turbidity, which required between an hour and a half and two hours' continuous attention, and the passage of nearly a gallon of water, the acute pain was entirely subdued. There were certain difficulties in the operation which the simple appliances at hand rendered unavoidable; but the result was satisfactory enough to encourage the belief that those processes of decomposition which give rise to gaseous and inflammatory products in the peritoneal cavity may be dealt with on the general principles of antiseptic treatment.

R. J. LEE, M.D., Assistant-Physician
to the Children's Hospital.

PATHOLOGICAL MEMORANDA.

CAN A DEAD MAN GROAN?

THE possibility and probability alike of such a circumstance as the utterance of a groan after somatic death are sufficiently heterodox to ordinary credence to induce me to record the fact of my having, in connection with others, heard a veritably dead man groan.

J. B., aged 57, committed suicide by hanging, and, after he had been very effectually suspended for an hour, was cut down by me and two others. As the doubled rope was slackened from the neck, air escaped from the thorax through the larynx, and a prolonged rather loud groan was the consequence. The two men who assisted me exclaimed, "He ain't dead"; and I, for the moment, fell in with their views, ripped open his clothes, and practised artificial respiration; but I soon noted that there was not the slightest attempt at respiration; that the heart was still to eye, hand, and ear; that his well opened eyes were glazed as only a dead man's eyes glaze, and that the dilated pupils were insensible to strong light. He was certainly dead, and dead from the first, and the groan we all heard had, I imagine, the following causation. The suicide braces his body for the final throes by taking in a deep breath; and, when hanging is the method adopted, the constriction of the air-passages is too immediate and effectual to allow this air to escape; but, when the rope is relaxed, the lungs and thorax contract with sufficient force to occasion a groan even an hour after death. Such a positively observed fact may find its importance in a medico-legal sphere, and I feel that it ought to be contributed to the *répertoire* of such as it may interest.

E. HOLLAND, M.D.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN
THE HOSPITALS OF GREAT BRITAIN.

ST. THOMAS'S HOSPITAL.

CASE OF STRANGULATED INGUINAL HERNIA: OPERATION: SAC NOT
OPENED: IMMEDIATE UNION: RECOVERY.

(Under the care of Mr. F. MASON.)

THE patient in this instance was a man, aged 47, married, who was admitted into Albert Ward, under the care of Mr. Simon, on October 15th, 1874. It appears that he had had an oblique inguinal hernia on the right side for twelve years, for which he had worn a truss. He was a railway-porter, and was exposed to a good deal of physical labour, yet the instrument kept the rupture from protruding. He was quite well until the day of admission, when, in consequence of having a painful carbuncle over the iliac crest of the left side, he removed the truss. About 3 P.M., as he was walking across the room, the hernia descended, and all attempts on his part to return it proved ineffectual. He was admitted into the hospital at about 6 o'clock, and an ice-bag was applied for some time, when Mr. Simon was sent for, in consequence of the symptoms of strangulation becoming urgent. Mr. Simon being absent from town, Mr. Mason was called to the case at 12.30 A.M. on October 16th. On his arrival, the patient complained of a good deal of abdominal pain, and the hernia protrusion was so tender as to preclude a careful examination of the part. The patient had vomited, but the contents of the stomach were not markedly stercoraceous. It was decided to give the patient chloroform, and, if necessary, to operate. The patient having been removed to the operating-theatre, chloroform was administered, and, moderate taxis proving unavailing, Mr. Mason transfixed the skin over the neck of the hernia, and, dissecting carefully with the forceps and knife only down to the peritoneal sac, passed his finger into the external abdominal ring. A hernia-knife was then employed, and an incision made in an upward direction through a tight constricting band. The limb was then flexed on the abdomen, and the hernia instantly returned into the abdominal cavity. Four silk sutures were applied to bring the edges of the skin together, and a pad and bandages having been adjusted, the man was taken back to bed. The subsequent history is briefly told; for, when the patient was dressed at 9 A.M., that is about eight hours after the operation, the wound was found perfectly healed. The stitches were removed on the following day; the wound was firmly closed, and not a single drop of pus was seen throughout. The patient was discharged well on October 30th, having been kept in the hospital until the carbuncle was cured.

REMARKS.—Mr. Mason observed, that so satisfactory a termination after an operation for strangulated hernia was exceedingly rare; and it was the more surprising in this case, inasmuch as the carbuncle from which the patient suffered indicated that the man was not in the best of health. Mr. Mason thought that the successful result was due partly to the little delay that existed before the operation, and in some measure to the sac not having been opened, but perhaps more particularly to the fact, that the incision into the constricting band was a fairly free one, which allowed the hernia to be gently returned without in the least bruising the intestine. With regard to the prolonged use of taxis, Mr. Mason added that he believed that some patients, with the view of avoiding an operation, employ an unjustifiable amount of force in their endeavour to put back the rupture. In dealing with any individual case, the surgeon should take this previous automanipulation into consideration, and, if there be much local pain, the division of the strictured part should be at once recommended. The operation was simple, if done early, but delay in strangulated hernia was well known to be especially dangerous to life.

HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM.

PARAPLEGIA: RECOVERY.

(Under the care of Dr. LOCKHART CLARKE.)

THE following case is one of great interest, and records an example of remarkable success in treatment.

J. M., aged 46, was thrown from a chaise in August 1870, and violently pitched on to a hard road. He turned a complete summersault, and fell on his back. He was quite stunned, and remained insensible or upwards of half an hour. A large and painful lump formed at the

back of his neck, and for some two or three months afterwards he used, at night when in bed, to feel a dull heavy pain extending up the back part of his head. All effects of the fall, however, seemed to have disappeared, when, in September 1872, after two days' shooting, he suddenly felt an extreme coldness in his right foot for four or five minutes while sitting down. The same feeling was experienced in the course of a few days, and then recurred more frequently, the left foot also being sometimes affected in the same way, but never at the same time as the other. These symptoms were succeeded, about a month later, by stiffness of both knee-joints, followed by numbness in the leg, thigh, half the penis and scrotum, abdomen, and loins, on the right side. There was no loss of power, however, on that side; but the left leg was very weak, and he dragged it in walking, although he felt scarce any perceptible numbness in it at that time. In the right leg, besides the numbness, there was great loss of sensibility to heat and cold. For some months, he had been under medical treatment, and had taken nux vomica and iodide of potassium, with cold douche and shampooing to the back, and faradisation. However, the disease progressed until he became almost entirely paraplegic. He came into the hospital on February 5th, 1874. He was then unable to stand without support. He had hyperæsthesia of the right leg, and almost total anæsthesia of the left. Muscular startings in both legs were severe and distressing, but reflex action was diminished. His urine was thick, scanty, and loaded with lithates. On examination of the spinal column, considerable pain was found to be caused by pressure over the sixth and seventh dorsal vertebrae, and again over the tenth and eleventh. He was ordered a blister, five inches by two in size, over the tender space in the dorsal region of the spine, with the following draught:—Liquoris potassæ 3ss.; potassii iodidi gr. v; spir. ætheris nitrosi, ʒi; spiritus juniperi 3ss.; tinct. belladonnæ, ℥v. At the end of a week, another blister was applied over the tenth and eleventh dorsal vertebrae, and, a week afterwards, another was applied to the same place as the first, over the sixth and seventh dorsal vertebrae. These blisters were followed by diminution in the startings of the legs, and had also the effect of removing to a considerable degree the tenderness on pressure. In about a month, there was a very decided improvement in both the power and sensibility of the lower extremities. He could lift his legs a considerable height from the ground while sitting: a movement which he was wholly unable to perform when he came into the hospital. The hyperæsthesia of the right leg and the anæsthesia of the left had evidently diminished. He continued the same medicine, with repeated blisters at intervals to the spine whenever there was any tenderness on pressure or muscular jerking of the legs. At the end of two months, he was able to move about the ward with the assistance of two sticks; and, a few weeks later, he could walk round the garden at the back of the hospital. It was now considered better that he should leave the hospital and go to a relative in the country, but continue the same medicine and repeat the blister when necessary. He left on August 27th, and continued steadily to improve. In the course of six weeks, he wrote to say that he could very well walk a mile and a half without fatigue, and, a few weeks later, he called at the hospital to show himself, stating that he considered himself almost perfectly well. The number of blisters applied to the spine was fourteen.

The symptoms in this very satisfactory case were evidently due to a subacute or almost chronic inflammation of the spinal cord and its membranes, and the success of the treatment was in favour of this diagnosis.

GENERAL HOSPITAL, BIRMINGHAM.

FATAL CASE OF VOLVULUS.

(Under the care of Mr. PEMBERTON.)

[Reported by W. OTTLEY, M.B., House Surgeon.]

G. A., aged 50, a pauper imbecile, was admitted on March 21st, with a history of constipation and occasional vomiting, there being at the same time a tumour in the right inguinal region. Owing to his being dumb, and to his complete absence of intelligence, a very imperfect history was obtainable, but it was ascertained that he had been in his usual health until Thursday, March 18th, and the master of the workhouse stated that no tumour had been noticed in the groin until after that date. On examination, the abdomen was found to be moderately tense, but there was no marked tenderness of this or of the tumour before mentioned, which was of the size of a large egg, very hard and solid to the feel, without impulse on coughing, and not painful, even on moderately firm pressure. It was rounded and smooth, was not translucent; it occupied the right inguinal canal. There was no redness or œdema of the skin over it. The testis on this side was absent from the

scrotum. On the other side, the testis was natural in shape and size; there was a scar of doubtful nature on the penis, but no enlargement of inguinal glands nor any other evidence of syphilis. The tongue was moist, slightly furred. March 22nd. He passed a very restless night, sitting up in bed, and occasionally getting out on the floor. He refused all nourishment; there was no change in the condition of the tumour; the bowels were not opened; there had been no vomiting. He was ordered an enema, and a draught containing twenty grains of hydrate of chloral and 30 grains of bromide of potassium at night. March 23rd. He vomited once. The enema was returned unchanged. March 24th. Tympanitis had decidedly increased, and there was considerable abdominal tenderness. Vomiting had occurred again, and the man was weaker. In the presence of these symptoms, it was decided to make an exploratory incision into the tumour in the groin. The man being put under the influence of ether, an incision four inches in length was made over the axis of the tumour, and the dissection carried down to the sac, on opening which about two ounces of serous blood-stained fluid escaped, and the enlarged and adherent testis was brought into view. The sac (which was that of a congenital hernia, there being an opening into the peritoneal cavity large enough to admit the finger) was found to be empty, and a careful search having failed to reveal the seat of obstruction, the wound was closed. March 25th. The patient had very little pain after the operation, and slept a little during the night, though he continued to sit up, and to attempt to get out of bed in the intervals of waking. In the morning he was very much weaker, the abdomen greatly increased in size, and breathing much interfered with. He died about 1 P.M. At the *post mortem* examination, on opening the abdominal cavity an enormous coil of large intestine was found extending from the left iliac region to the diaphragm, filling the left hypochondrium, and curling down to the sacrum. It was as large round as the man's knee; its walls were thin and membranous and contained a large quantity of fluid, besides the gas which distended it. The small intestines were also blown up, and had pushed the diaphragm as high as the third interspace on both sides; the liver was thrust back against the spine. It was found that the coil of large intestine consisted of the sigmoid flexure which had been twisted a whole turn on itself, its channel being thereby completely obstructed, and the bowel had been so nipped that there was ecchymosis under the peritoneum at the seat of twisting. There was a second volvulus of the ileum, the mechanism of which is difficult to describe; but it appeared as if the gradual distension of the sigmoid flexure had twisted the greater part of the small intestine in one direction, the mesentery being rolled up; one coil, however, had received a twist the opposite way, and where the two pieces crossed, the bowel had been strangulated; there was ecchymosis at this point, and a few flakes of lymph were found near the spine. There was a congenital opening into the tunica vaginalis, through which a hernia might have descended; the testis in the right inguinal canal was hard and fibrous, containing several cheesy patches and without a trace of testicular structure. The bases of both lungs were collapsed from pressure by the abdominal contents.

REVIEWS AND NOTICES.

CONTRIBUTIONS TO THE MECHANISM OF NATURAL AND MORBID PARTURITION, INCLUDING THAT OF PLACENTA PRÆVIA. By J. MATTHEWS DUNCAN, President of the Obstetrical Society, Edinburgh. Edinburgh: A. and C. Black. 1875.

DR. MATTHEWS DUNCAN has already obtained so high a reputation for his philosophical and accurate treatment of all the mechanical questions involved in parturition, that very high anticipations are raised by the appearance of another volume devoted to this special subject, and these are not disappointed in its perusal. In this, as in former works, the author is especially remarkable for the ingenuity displayed in devising experiments, whereby positive data are obtained for the solution of problems which had previously been the subject of uncertain inferences. In the more theoretical part of the discussion, we find that mechanical questions, which some authors have, by elaborate research, involved in greater obscurity, are always definitely and lucidly stated, and for the most part treated with accuracy and soundness. The book now before us, in conjunction with his former works, is sufficient to place Dr. Duncan in the very first rank of those who have contributed to the advancement of obstetrical science.

The present book, like the *Researches in Obstetrics*, consists of a collection of papers published at various times, and includes a reprint of those chapters of the former work which relates to the subject of mechanism. It thus forms a somewhat more complete whole than the other, comprising a consideration of most connected and mechanical points which are now open to discussion. Among the chapters reprinted,

which will not now call for special notice, are those on the power exerted in ordinary labours, the maximum power in difficult cases, the strength of the uterus to resist bursting pressure, the pelvic articulations in parturition, the lateral obliquity of the fetal head, and the relation of the caput succedaneum to the presentation.

In the introductory chapter, the author divides the progress of the science into three stages: first, the measurement of the passage to be traversed, and the body to be pushed through; secondly, the discovery of the manner in which the fetus traverses the passage, and the alterations in form thereby produced; and, thirdly, the study of the forces employed to do the work. Of these, the first stage is already achieved; the second is far advanced, but still far more complete; while the third is as yet hardly commenced, but is far from complex, and promises more conspicuous practical results than either of the others.

The second chapter treats of long delay of labour after the escape of the liquor amnii; and a case is related, showing that the fetus may survive as long as forty-five days under such circumstances, provided the uterus remains quiescent.

In the third chapter, Dr. M. Duncan discusses the curves of the developed genital passage. He controverts the opinion of Schatz and Schultze, that there is normally a posterior obliquity of the axis of the uterus in relation to the axis of the pelvic brim, and the practical conclusion drawn by the latter with regard to the position which ought to be assumed in the different stages of labour.

He next points out that there is commonly a lateral curve in the genital passage, due to the obliquity of the axis of the uterus towards the right side. In this circumstance, he finds an explanation of the mode of causation of brow and face presentation, discussed in the fourteenth chapter. A point is here involved, which is not only of theoretical interest, but has an important practical bearing in relation to the position which should be adopted in such cases; and the author appears to be not so clear as usual in the mechanical grounds upon which his conclusion is based. He assumes that resistances are uniform; and states that, when the fundus uteri is inclined to the right, that part of the fetal head which is toward the left will be pushed down most, because the line of force will be nearer to the outer side of the curve. In this way, he considers that a face-presentation may be produced when the occiput is towards the right, and finds a confirmation for this explanation in the fact shown by statistics, that face-presentations are relatively more frequent in the second than in the first position of the head. Now, it is clear that the resultant of the uterine force will be parallel to the axis of the uterus, and that, so long as there is no lateral flexion of the fetus, its line of action will lie in the median antero-posterior plane of the fetal head. The effect of this force in rotating the head on a transverse axis, and so forcing down one extremity more than the other, is measured by the product of the force, and the perpendicular from the centre of gravity of the head upon its line of action. It depends, therefore, solely upon the point at which this line of action cuts a transverse plane drawn through the centre of gravity of the head. And this will be the same, whether the head enter the brim directly or obliquely. The fact that, in the latter case, the line of action passes nearer to one side of the passage, does not affect the question.

It appears, therefore, to us, that Dr. M. Duncan has discovered the true cause of face-presentations, but that its mode of operation is somewhat different from that which he describes, and is to be found in the inequality of resistances. If the fetal head enter the brim obliquely, it will first encounter that margin of the brim which is nearest, namely, that which forms the inner side of the laterally curved passage. The part of the head which is on the inner and shorter side of the curve, will, therefore, be first resisted and retarded, and, if the occiput of a dolichocephalic head be turned in this direction, as in the second position of the vertex, it may become hitched upon the edge of the brim. When the head is fully engaged in the brim, a similar effect will be produced up to a certain point, but in a different manner. The pressure, and therefore the friction, will then be greater on the outer and longer side of the curve, towards which the line of force is inclined. So far as regards friction, therefore, the outer extremity of the diameter will be most retarded. But an opposite, and usually a preponderating effect will be produced by the excess of perpendicular pressure at this end of the diameter. In consequence of the elongated shape of the head, the direction of this force will, so long as the largest diameter of the head has not yet entered the brim, meet the longitudinal axis of the head at a point in advance of its centre of gravity. When this is the case, it will tend to produce such a rotation on a transverse axis, that the part of the head on the outer and longer side of the curve will descend most rapidly. It is in the same way that the resistance of the antero-posterior curve of the pelvic passage produces extension of the head in the later stage of normal labour.

Precisely the same mechanical point is involved in the question, also discussed by the author, of the effect of anterior or posterior obliquity of the uterus, in relation to the axis of the brim, in producing lateral obliquity of the fetal head. The confusion which has existed on the subject is shown by the fact that Scanzoni and Litmann have attributed to the same causes exactly the opposite effects to those which Dr. Duncan, with good reason, considers them to produce.

In the seventh chapter the effective power of parturition is discussed, and the danger and difficulty pointed out, which are inherent in the method of calculation adopted by Professor Haughton, leading to the conclusion that the auxiliary forces exceed that of the uterus in the proportion of about ten to one, and amount to a total of nearly a quarter of a ton. By estimating the force required to check the advance of the head, the author infers that the total force naturally exerted rarely exceeds fifty pounds.

The ninth chapter contains an account of experiments on the tensile strength of the fresh adult fetus; and an inference is drawn as to the amount of force applied in podalic extraction, which is compatible with the life of the child. It is shown that the spinal column gives way under a tension varying from ninety to one hundred and fifty pounds, and that an addition of less than twenty pounds more is sufficient to produce decapitation.

In the tenth chapter, the author investigates the question of the synclitic motion of the fetal head, which Kuenke has described as taking place while it traverses the true pelvis, and the enclitic motion which he believes to occur in the last part of the passage. By the former of these not very lucid expressions, Kuenke means such a motion that the same plane of the fetal head, which is at first coincident with the brim, becomes coincident in turn with the successive planes of the pelvis, so that the head descends as if fixed to a lever moving on a hinge at or near the symphysis pubis. Dr. Duncan forcibly demonstrates the fallacy of the explanation given by Kuenke for this supposed motion, namely, that the pressure of the curved posterior wall of the pelvic passage causes a corresponding pressure of the head against the symphysis; and that this latter pressure produces a greater retardation at the anterior end of the diameter than the former does at the posterior. This explanation amounts, as he shows, to an assumption that the reaction is greater than the action.

The sixteenth chapter contains an explanation of the true mode in which the placenta is naturally expelled, and a refutation of the view commonly entertained, and expressed by Ramsbotham, Rigby, Schultze, and others, that it descends like an inverted umbrella, the point where the cord is inserted coming foremost. Dr. Duncan points out the fact, which every observer can verify for himself, that, when no traction is made on the cord, and there is no excessive effusion of blood, it is the edge of the placenta, and not the point of insertion of the cord, which first presents at the os uteri. He shows that normally the placenta becomes folded upon itself about a longitudinal axis.

The last five chapters of the book are devoted to a very full discussion of the several points of mechanism connected with placenta prævia, including the spontaneous separation of the placenta, the causes and source of hæmorrhage during pregnancy and labour, and the mechanism of its arrestment. Hæmorrhage in the earlier months of pregnancy, if not due to commencing abortion, the author considers to be analogous rather to the accidental hæmorrhage which may occur when the placenta is normally situated. He controverts both the old traditional view that it depends on an expansion of the cervix during the later months of pregnancy, and also the theory of Dr. Barnes, that it is due to the excessive proportionate growth of the placenta, because the latter involves the erroneous notion that the cervix can be the placental site. He shows that the spontaneous separation of the placenta is due to the lateral stretching, and not, as Dr. Barnes has supposed, to the longitudinal shrinking of the uterine wall, since otherwise separation would occur at the normal site, where a corresponding amount of shrinking may take place at the escape of profuse liquor amni. He considers Dr. Barnes's estimate of the diameter of the zone of necessary separation to be too great. The arrestment of hæmorrhage he attributes mainly to the lowering of venous pressure produced by the hæmorrhage itself. He regards, however, as important aids towards this end the effect of the pressure upon the open mouths of the vessels, and the elongation of their orifices, which are produced by uterine action.

We have endeavoured to give some outline of the more important topics discussed by Dr. Matthews Duncan, but to all our readers we commend the book itself, and especially to those who are themselves students of the mechanics of parturition. It will be found not only to convey most valuable instruction, but to be fruitful in suggestions to scientific observers in pointing out those lines of investigation which are most likely to afford further discoveries in the future.

REPORTS AND ANALYSES AND DESCRIPTIONS OF NEW INVENTIONS IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

KINMOND'S EFFERVESCING FLUID CITRATE OF MAGNESIA.

IT is very well known that what is commonly sold as granular effervescing citrate of magnesia is in truth not a citrate of magnesia at all, but a tartrate of soda. A good deal of discussion and some legal proceedings have resulted from this unsatisfactory state of things, and some of the leading chemists have proposed various compromises in the way of title. But, as the soluble salts of magnesia have decided advantages, and are those which the prescriber desires for his patient, it is a good idea which Messrs. Kinmond and Co. of Leamington have had in issuing in a duplex bottle a fluid magnesia of double the official strength, and (in the attached smaller compartment) a solution of sweetened citric acid. Half a teaspoonful of the citric solution added to a tablespoonful of the magnesia solution gives a true effervescent solution of citrate of magnesia.

MR. SYDNEY JONES' OVARIOTOMY-FORCEPS.

THIS forceps has many advantages over those previously made for ovariectomy. First, the handles are longer than Nclaton's, by means of which they are not so much in the way of the operator. Another great advantage is, that the instrument never tears the walls of the cyst, because the holding parts of the places fit well into each other, as shown in the diagram. Lastly, near the bow, is a rack similar to

that of a hæmorrhoid-forceps. The ovariectomy-forceps has been in use at St. Thomas's Hospital for some time, and has been much admired by several of the staff.

ETHER-FLASKS.

STAFF-SURGEON DR. JAMES LILBURN has invented a very useful method of closing bottles containing ether, chloroform, and other volatile fluids or tinctures, in hot climates. The bottles are made with a narrow neck, corked, and the glass of the neck drawn over the cork and closed with the blow-pipe. Evaporation is impossible. The invention is very simple and practical, and his ether-flasks, after being tried and found successful, are, we understand, to be adopted at foreign stations.

DR. VON BRUNS'S WOUND-DRESSING COTTON.

VON BRUNS's dressing cotton for surgical use possesses many advantages which must, we think, recommend it for use in hospitals and public institutions. It is entirely free from grease, very pure and white, and is in every way a most convenient material for all kinds of surgical dressing, either as an absorbent of discharges, an elastic compress or tampon, a cushion or envelope. It merits, and we think would repay, trial by surgeons. It is supplied by Krohne and Sesemann, Duke Street, Manchester Square.

BRITISH MEDICAL ASSOCIATION: SUBSCRIPTIONS FOR 1875.

SUBSCRIPTIONS to the Association for 1875 became due on January 1st. Members of Branches are requested to pay the same to their respective Secretaries. Members of the Association not belonging to Branches, are requested to forward their remittances to Mr. FRANCIS FOWKE, General Secretary, 36, Great Queen Street, London, W.C.

BRITISH MEDICAL JOURNAL.

SATURDAY, MAY 1ST, 1875.

THE SANITARY ADMINISTRATION OF THE LOCAL GOVERNMENT BOARD.

It only needed the publication of the reports of the general inspectors of the Local Government Board, on their proceedings in initiating the Public Health Act, 1872, to complete the strange story of the sanitary administration of that Board under Mr. Stansfeld's presidency. These reports have now, thanks to Mr. Stansfeld himself, been laid before Parliament, and he has already, in his place in the House of Commons, taken occasion to refer to them as justifying his sanitary policy by the "great progress" in local sanitary organisation which they show. It will be remembered that Mr. Stansfeld's policy, according to his utterances first before a deputation from the Executive Council of the British Medical Association in November 1872, and again at Halifax in January of the present year, was, before all things, a policy of local health self-government. In pursuit of his policy, he selected for his agents in interpreting the Public Health Act, 1872, to the sanitary authorities newly created by it, the former Poor-law inspectors: a selection determined by the familiarity which already existed between these gentlemen and the rural sanitary authorities, and by the confidence which the Board reposed, as the result of long experience, in the judgment with which they would act as "negotiators" between the local bodies and the Board. These inspectors, following a Poor-law precedent, were directed to invite and promote conferences with local authorities, and to "work out" with them, in discussion, the different questions which would arise in the initiation of the Act, trammelled only by certain general indications of the Board's wishes. Without laying down any rigid rule as to the medical officers of health, and admitting that, under certain circumstances, Poor-law medical officers would be the best medical officers of health, the Board, while declining to express an opinion on the area over which such officer should be appointed, was, on the whole, in favour of joint appointments. But it was for the local authorities to discuss and determine what they should do, and for the Board to approve or not of such determination, and it expressed a hope that "local authorities would discuss schemes for the appointment, whether joint or separate, considering seriously whether they could not unite the appointment, and then that they would propound their schemes to the Board". The policy here explained had been instilled into the inspectors during "a couple of days" discussion between them and the president immediately after the passing of the Act, after which they were dismissed to their districts, "there to act as the interpreters and negotiators of the policy of the Board".

Any knowledge of the subject-matter of the Act on the part of the inspectors was held unnecessary, and, it may be inferred, even undesirable, as tending to interfere with the judgment of local authorities. The essential consideration in the initiation of the Act was the integrity of local self-government; and even such suggestions as the Board thought fit to make for the guidance of local authorities were to be held wholly subsidiary to this consideration, subject to the reservation of the Board retaining its power of approval or disapproval of any schemes submitted to it. Certainly, on the first of the occasions which have been referred to, Mr. Stansfeld spoke of his faith in the

power of local government bodies as being conditional on their direction and encouragement by impartial guidance, and he gave expression to some excellent precepts concerning minute sanitary work; but these observations had obviously no intimate bearing upon his sanitary policy, and they may be dismissed from consideration.

If now we turn to the reports of the inspectors entrusted with the interpretation of this policy to local authorities, the attention is at once arrested by several curious inconsistencies between their action and the policy of the Board as described by Mr. Stansfeld. Either we must assume that the sacred privilege of self-government, of which as regards local authorities the Board had, according to its own showing, become the tutelary genius, attached also to its own inspectors—in which case we have an inspector's policy superadded to the Board's policy; or, that the inspectors had widely misapprehended the Board's policy, thus betraying the confidence reposed in their judgment by the Board; or, that the policy described by Mr. Stansfeld in November 1872, as influencing the Board, was the outcome of some less defined preceding policy. The explanation of the inconsistencies is probably to be sought in the operation of all the conditions here assumed in various degrees.

It is apparent that the inspectors gave little heed to that sensitive regard for local self-government which Mr. Stansfeld describes as the essential feature of his policy. They went to their districts possessed with the notion that the new duty imposed upon them involved very active and energetic work in advising the local authorities, and, so far from simply setting the new organisations in motion with such suggestions and in such manner as the Board had recommended, they submitted to them very definite detailed schemes, and urged these upon the authorities with a remarkable persistency. Mr. Hedley understood that the inspectors had to give detailed consideration to the circumstances of each district, in advising the local authorities as to making appointments; Major Cox (acting temporarily for Mr. Peel) "urged strongly" combined appointments; Mr. Farnall submitted "precise suggestions for combination" to the local authorities in his district; Mr. Wodehouse urged joint appointments; Mr. Corbett "invariably sought, in the first instance, to attain" such appointments, having recourse to "personal conferences and remonstrances with recalcitrant Boards"; and so forth. Clearly, the inspectors entered upon their tasks with such a notion of local sanitary government as was derived from their experience of local Poor-law government, with regard to which they exercised much more considerable powers. We are not surprised to find, therefore, not a few of the inspectors lamenting their want of compulsory powers to carry out the notions of the Board, and urging the necessity of such powers. One only seems to have a shadowy notion that possibly, in addition to difficulties arising out of certain hesitancy of new authorities to undertake their duties, there might be difficulties arising out of the previous relations between the inspectors and the authorities in Poor-law government. Mr. Wodehouse deprecates hasty dealing with the authorities, and observes, "already, in certain matters connected with Poor-law administration, such as the appointment and removal of officers, and the detailed plans and construction of workhouse buildings and infirmaries, there is reason to believe that the control exercised by the central authority has deterred some gentlemen, who would be useful members of boards of guardians, from taking part in their proceedings, because they consider that their hands are too much tied to enable them to discharge with efficiency the duties imposed upon them". Few things, indeed, have contributed more to prejudice new sanitary authorities, and especially urban authorities, against the inspection of the Local Government Board, than the impression that the inspectors could exercise as much vexatious power in sanitary administration as in Poor-law administration. Their selection as sole interpreters of the Local Government Board was on this ground alone a blunder (Mr. Stansfeld notwithstanding), which their meddlesomeness and want of knowledge served to aggravate.

If the inspectors and their president were not in thorough concord as to the spirit in which they approached local government, they were still

less in concord, where concord was most desirable with him, and also among themselves as to the suggestions of the Board. It would appear from those reports, that the inspectors were not left to their unaided imaginations as to the opinion of the Board. The reports make reference to a certain instructional letter of the 17th August, 1872, issued by the Board for their guidance; but this letter, although it forms the text, as it were, on which the various reports comment, is, strange to say, not printed, and only one paragraph from it, so far as we have made out, appears in the course of the reports, namely, in the report of Mr. Wodehouse. If the reports be read in the order in which they are printed, the reader would come to the conclusion that the Board's views in favour of joint appointments of medical officers of health had actuated the advice of the inspectors throughout. When, however, the reports are arranged in order of the time when the inspectors began their new duties, a very different result is obtained. Mr. Doyle was the first in the field; and he, coming fresh from the "couple of days" discussion with the Board, recommended the several Boards of Guardians in his district "to appoint the medical officers of each union officers of health, each in his own district"; and Mr. Hedley tells us that the Board, in the instructional letter referred to, "appears at that time to have contemplated that, as a general rule, the district medical officers were to be appointed as medical officers of health, each one acting for his own poor-law district". The quotation from the instructional letter given by Mr. Wodehouse completes all that need be said on this part of the subject. It is as follows: "Where the services of a medical practitioner possessing superior qualifications for the office are likely to be obtainable, it is desirable that the appointment should be for the whole sanitary district, or for two or more adjoining districts." Those of our readers who are attached to puzzles will find a charming exercise in attempting to reconcile these different utterances with the utterances of Mr. Stansfeld.

By the time we have got thus far in the analysis of the reports, we are quite prepared to accept as consistent parts of the policy of the Board, the various suggestions of the inspectors as to the area fitted for an officer of health. Mr. Hedley prefers a county; Mr. Wodehouse "is not prepared to go quite so far", and recommends, after Dr. Budd, the Parliamentary division of a county; Mr. Baldwin Fleming prefers the "union area" as the unit for appointments, at least in the first instance; Mr. Doyle fixes the area of the poor-law medical officer's district; and so forth.

Mr. Hedley thinks that the "advance which has been made in the path of improved sanitary organisation", under the wondrous policy here briefly indicated, "may easily be underrated by those who look to ends only, in disregard of means". We prefer to look at the means with reference to the ends they are designed to accomplish. Now, it has been commonly understood that the object of the Public Health Act, 1872, was to bring every part of the kingdom under the influence of such a form of sanitary organisation as had been shown by experience to be most beneficial in previously organised districts. The functions of a medical officer of health and of an inspector of nuisances were perfectly well known, and these have been not inaptly set forth in the regulations as to these offices issued by the Local Government Board. But Mr. Hedley has no hesitation in setting aside previous experience on the subject and stultifying the regulations of his Board, by writing: "It is not easy to overestimate the importance of the efficient discharge of the duties appertaining to the office of inspector of nuisances. The majority of the sanitary defects in the country arise from faulty construction or from simple neglect to remove filth. The former may require some engineering skill for their correction; but the latter can be detected and abated by the exercise of our common senses and our common sense. Such are ninety-nine out of every hundred village nuisances, against which the inspector has to wage incessant war. It is only in those more serious and happily rarer encounters with enemies, whose detection and extermination require the insight and accuracy of science, that the intervention of the medical officers of health will be indispensable. In ordinary times, and under ordinary circumstances, it

is the inspector of nuisances who will fight the sanitary battle." Mr. Wodehouse regards the action of the inspector of nuisances as the means of educating authorities up to a proper appreciation of the utility of a medical officer of health; Mr. Corbett "pressed on" the appointments of inspectors of nuisances before those of medical officers of health, in order that the new authorities might obtain through them "the fullest information on the sanitary condition(?)" of their districts; and so from report to report we find the prevailing notion among the inspectors that sanitary work and the prevention of disease simply mean the removal of obvious nuisances and the arrest of spreading diseases when they happen. Comprehending the duties of the inspector of nuisances more fully than those of the medical officers of health, they naturally have given prominence to the former at the expense of the latter, and thus reversed wholly the teachings of sanitary experience. The intelligent conception of the ends arrived at in reference to the prevention of disease by the removal of nuisances, which it is the primary object of the medical officer of health to supply, has no place in their advice to sanitary authorities; and the chief measure of success with them in the sanitary organisations which have been effected under their supervision is the abatement of nuisances as ordinarily conceived.

Advice such as this, which reverts to rudimentary conceptions of sanitary administration, and for which the Local Government Board is alone responsible, has largely frustrated the ends which alone justify the appointment of a medical officer of health, and has too commonly interposed no inconsiderable difficulty in the proper discharge of his duties.

PUERPERAL PERITONITIS AT CREWE.

THE recent sentence of a midwife at Manchester for attending women in labour, after she had been cautioned by a medical man not to do so, has created great alarm in the northern counties. We have commissioned a correspondent at Crewe to make inquiries, where an outbreak of puerperal fever had been announced, as to the state of the register of deaths, and, after a careful examination, he states that there have been four cases of puerperal peritonitis, and one of peritonitis immediately after childbirth. It was currently stated at the guardians' meeting, on the previous Saturday, that there had been nine cases of deaths from puerperal fever, but the person who examined the register had probably included the deaths of some women after labour, from causes particularly incidental to women at that period. Dr. Haughey, medical officer to the Nantwich Board of Guardians, had the misfortune to have three cases of puerperal fever, one of peritonitis simply, and Mr. Vaughan attended the other patient at a little village called Hough, near Wybunbury. The deaths in the case of Dr. Haughey occurred, the first on March 20th, the 21st, 26th, and April 2nd. Mr. Vaughan's occurred on the 26th. It will thus be seen that the whole of the deaths took place within a period of ten days. There have, as we have already stated, been a singularly large number of deaths from causes incidental to women in labour, and all these have been seized upon, and currently reported as having been caused by the fever epidemic. The excitement in Crewe, on the appearance of the brief reports in the northern dailies, was very great, and several of the more well-to-do mechanics and tradesmen have sent their wives away to be confined. The Local Government Board have been telegraphing for information as to the extent of the ravages of the disease, but when it is stated that there are only four well authenticated cases on record, the anxiety felt in all quarters will now be considerably modified.

The subject came before the Crewe Local Board at its monthly sitting on Wednesday week. The following letter from Dr. Haughey, addressed to the Chairman, was read by the Clerk.

"Sir,—With the intention of allaying the unnecessary alarm which the allusion in the papers may create as to the prevalence of puerperal fever in Crewe, I venture to address a few remarks upon the subject. Careful investigation has conclusively proved that the disease called puerperal fever prevails epidemically, and that there are conditions which favour infection with the poison in the puerperal state, just as there are conditions which predispose to infectious and malarious diseases in

the non-puerperal state, such as exposure to sewer-gas in badly drained houses, and depressing emotions, fear, and dread. We have often observed that puerperal women exposed to the poison of zymotic diseases, such as scarlet fever and measles, or to erysipellatous contagion (especially if the vital systems, nervous, circulatory, or mental, are excited or not in a state of health) are liable to be attacked with some form of puerperal fever. But it is also believed that puerperal fever is produced from poisoning of blood induced by inflammation of patient's own tissues and decomposing matters in the uterus. I admit the possibility of fever being conveyed by accoucheurs, nurses, and visitors, but more especially by nurses, as they are more in contact with the patient, especially if strict precautions are not observed as to cleanliness, disinfectants, and change of dress. If these precautions are taken by those attending midwifery, the possibility of conveying disease is very doubtful. Of the fatal cases which occurred in my practice, I can only attribute one to puerperal fever, so-called, the remainder having died either from improper nursing or exposure to cold, and other internal complications not in any way connected with the puerperal condition. I have not been able to trace any history of contagion or infection in the deaths from childbirth in my practice, because the interval between the deaths was very considerable, and during the time I attended a great number of cases who made good recoveries. In order to take every precaution, I have not delivered any cases of labour for three weeks, and have secured the services of a medical gentleman, who has been surgeon on board-ship and is fresh from the sea-air, to attend to my patients."

"P.S.—Puerperal fever, like all other zymotic diseases, is likely to be engendered by decomposing animal matters; hence the importance of antiseptics and efficient sanitary measures."

A special report upon the disease was also read from the medical officer to the board (Dr. R. Lord), but he merely "deplores what they feel powerless to remedy", although he has ordered every sanitary precaution to be taken.

The board had a long discussion, and the result was that the Clerk was ordered to write to the medical men and midwives in the town, asking them to use every precaution against spreading the disease. No death has occurred since those enumerated.

It is now to be hoped that we have heard the last of this case. Presuming that these cases are favoured by unsanitary conditions, it must be confessed that Crewe presents a favourable field for the spread of disease. At the monthly meeting of the Local Board last week, it was stated that the ashpit contractor was just four hundred pits in arrear, and, with the summer sun streaming in upon these, it will not cause surprise if fever of other kinds is soon rife in the town. Then, again, the water is described to us as being "about the vilest liquid possible, being full of animalcules and sediment". These are conditions favourable to the spread of any zymotic form of disease, both by the facility with which contagia are thus conveyed, and probably, also, by the constitutional depression which they produce.

It is stated that Mr. Wheelhouse of Leeds, and Mr. Hussey of Oxford, will be brought forward as candidates for seats in the Council of the Royal College of Surgeons.

THE Marquis of Lansdowne will preside at the sixty-first annual dinner of the Royal Hospital for Diseases of the Chest, City Road, to be held on the first Wednesday in June. The Grocers' Company have given one hundred pounds, and the Brewers' Company twenty guineas, to the funds of this hospital.

SURGEON-GENERAL THOMAS LONGMORE, C.B., Professor of Military Surgery in the Army Medical School at Netley, and Honorary Surgeon to Her Majesty the Queen, has consented to take the chair at the annual festival of the Fellows of the Royal College of Surgeons in July next.

THE *Correio Medico de Lisbon* announces the death, through suicide by shooting himself, of Dr. J. C. Mendes, surgeon of division, and for a long time director of the permanent military hospital in Lisbon. He was about fifty-six years old.

HIS Royal Highness Assistant Brigade-Major the Duke of Connaught recently visited the Norfolk and Norwich Hospital, after which he generously forwarded the sum of £50 in aid of its funds.

AMONG the candidates recommended by the Council for the Fellowship of the Royal Society are Mr. Ray Lankester, Dr. Risdon Bennett, Dr. Klein, and Dr. Dupré.

ONLY Dr. Risdon Bennett and Dr. Klein, among all the candidates selected, have any medical status. Dr. Klein is, however, not a practising physician, but is well known here as the able director of the laboratory of the Brown Institute at Wandsworth, under the auspices of Professor Burdon Sanderson, and for his very valuable histological and pathological researches, of which his work on the lymphatics and his recent investigation of the organisms of typhoid and sheep-pox are among the most recent. Dr. Klein was, in Vienna, an assistant of Professor Stricker. His labours since he settled in this country have amply justified the reputation which he brought to it.

THE medical profession cannot complain that they are not adequately represented in the Royal Society. For the last quarter of a century, medical men have been largely honoured by the Fellowship of this Society, and the judgment shown in the selection has been very generally admitted to be sound. Nevertheless, there is a feeling in the minds of many that the door by which they enter is too much of a side-door, and that, while eminence in medical science is recognised indirectly, it is not openly weighed at its just and apparent value. Medical men commonly enter the Royal Society either very late in life as an official form, or as physiologists, histologists, or for some piece of work in chemical biology. What often happens practically is this. A senior of a great hospital sees that the number of names on the staff with this trilateral decoration have fallen below the high average which properly illustrates the list of officers. Then some of the young juniors are told: "You ought to work for the Royal Society." This work is generally a piece of biological research very remotely connected with the real pursuits of his life, and only adopted for the express purpose of "getting into the Royal Society". That object achieved, the Society hears little more of its new Fellow, and sees little more of him, except in the tea-room, at the annual *conversations*, or at the Royal Society Club dinner. This, of course, is not the typical Fellow, nor is it the typical mode of work. But it occurs so often, that it has come to be accepted to be perhaps even more commonly the practice than it really is. The medical and surgical Fellows of the Royal Society include the cream of the profession, and the sound good sense and just influence of Professor Sharpey have to be thanked for making a very inadequate method work, on the whole, satisfactorily, as, in good hands, even defective instruments are often made to work; but there are various disadvantages in this mode of procedure. In the first place, it produces a good deal of sham physiological work, and tends probably in the end to discourage real physiological advance. So large a number of medical men of one grade or other have been introduced to the Royal Society on the score of single achievements which they have never followed up, that we are blinded in this country to the poverty of our physiological work and the thinness of real scientific and medical investigation by the number of crowned physiologists. The mode in which the sciences and researches collateral to medicine are dealt with at the Royal Society—distributing facile honours for little work, and really on other intrinsically good grounds—holds out no premium for the devotion of a lifetime to such research. It confounds the real workers with the workers *ad hoc*.

It is possibly owing to the peculiar relation of the biological sciences to the Royal Society, and the absence of any weighty encouragement, scientific or otherwise, that this country has no Biological Society where workers in biology can meet for mutual debate, encouragement, and comfort. The very august and sedate character of the sittings of that most distinguished body, and the fact that a large

proportion of its biological members become *emeriti* as biologists, after a very short essay, does not encourage the attendance of younger men, who can relate short notes of recent investigations, and discuss their work as it proceeds. The practice of meeting in sections would perhaps help the present desolation. Nothing is more exciting than sympathy: and the disgust with which mathematicians and astronomers hear of the labour bestowed on determining the development of a tooth, or watching the migration of white corpuscles, is not enlivening. Moreover, the severely abstract atmosphere of the place tends to divorce physiological research from its medical relations, and this, again, is an evil. We are inclined to think that the interests of biological science would be served by the formation of sections in the Royal Society, or by the foundation of a biological section.

THE interesting discussion on puerperal fever at the Obstetrical Society will, we hear, be reopened by Dr. Barnes at the next meeting of the Society on Wednesday next, May 5th. Professor Stoltz, Dean of the Faculty of Nancy, and Professor Howitz of Copenhagen, are expected to be present; and it is hoped that Dr. Arthur Farre will make a contribution to the subject under discussion. It is long since Dr. Farre, whose stores of experience must be great, and whose skill and erudition have been well approved, has made any public contribution to the knowledge of the art which he practises with distinction.

THE British Medical Benevolent Fund has received a donation of one hundred guineas from Mr. Erasmus Wilson, F.R.S., for the special fund for augmentation of annuities. Mr. Erasmus Wilson has reached that honourable stage in life when good nature ripens into munificence; he appears to pass no small part of his time in the occupation which he publicly eulogised this week in his official speech at the Installation of the Prince of Wales as Grand Master of the Freemasons, that of "leading the brethren to unite in the grand design of being happy and communicating happiness". The "grand design of being happy", *pace* Freemasonry, is a poor conceit; that of communicating happiness a much surer and nobler pursuit.

LORD LAWRENCE, formerly Governor-General of India, and more recently Chairman of the London School Board, has accepted the post of President of Guy's Hospital, in lieu of the late Mr. Gurney Hoare. His lordship presided for the first time at a General Court of Governors held at the hospital on Wednesday last. Old Guy's men will learn with regret that Mr. Birkett has retired from the office of surgeon to the hospital, the time having arrived when, according to the new rules of the institution, his term of office had expired. We presume that he will be appointed to the honorary post of consulting-surgeon to the hospital, in accordance with the precedent which has been followed in the case of the other physicians and surgeons who in recent years have retired from their active duties upon the staff. At the above named Court of Governors, Mr. H. G. Howse, late assistant-surgeon to the hospital, was elected surgeon; and Messrs. R. C. Lucas and Golding Bird, demonstrators of anatomy in the medical school, were both appointed assistant-surgeons. Mr. Cooper Forster is now senior surgeon to the hospital. Mr. Birkett's retirement, and the promotions consequent thereon, will necessitate considerable changes in the surgical department of the medical school. It is understood that Mr. Forster and Mr. Durham will be the joint lecturers on surgery.

THE Board of Trade have received intimation that a severe outbreak of yellow fever has occurred at Rio de Janeiro, and that the deaths amount to from twelve to fifteen daily. The despatch states that a considerable number of the crews of British vessels had fallen victims. Her Majesty's Minister at the Hague states that all arrivals from Rio will be placed under quarantine at the ports of the Netherlands.

THE usual publishers' medical advertisements continue to appear in the daily papers. One which we notice this week—such as have appeared without reproach for years—includes advertisements of books

on "The Uterus and its Appendages", "The Treatment of Fistula", "Constipated Bowels", "The Urine and its Derangements", "Diseases of the Urinary Organs", "Stone in the Bladder", "A New Successful Treatment of Cancer", "The Functions and Disorders of the Reproductive Organs", "Uterine Therapeutics", "Cancerous Growths", etc. Are any of these books intended for popular readers? We believe not. Then why advertise them to popular readers? In no other country, we believe, is such a practice tolerated. Does it add to the dignity of our profession, or to the edification of the public? If these books were written for general readers, or intended to be read by them, the practice would have a satisfactory meaning. But, if any suffering and deluded person should buy one of these books, he would find it couched in technical phraseology, addressed to a technical audience, and presupposing so much technical knowledge that only professional readers could master its contents or draw a sound conclusion. The purpose with which this system of advertising of medical books in daily papers is commonly believed to be carried on by many, though certainly not by all or even by the majority, was very broadly and intelligibly stated recently by the President of the Harveian Society. There can be no doubt that his strictures have a considerable force and a wide scope of application. Why should a practice which is open to so many objections be continued?

DR. LYON PLAYFAIR last week asked the President of the Local Government Board whether he had obtained any report from the Medical Officer of the Local Government Board on the practical efficiency of the Public Health Act; and, if so, whether he would lay it before the House of Commons. The answer was, that no such report had been obtained. This is, of course, very significant and entirely consistent. It was perfectly well known that the jealousy of the Medical Department of the Local Government Board was such that Mr. Simon, the chief repository of knowledge in this country on the subject of the methods, powers, and results of sanitary administration and executive work, was not consulted on the passing of the Public Health Act; and that, if he had been, it would have been free from the gross blunders which have marred its conception and arrested the progress of sanitation throughout the country. It is quite consistent with this course, that the Local Government Board should carefully abstain from taking the opinion of their own highly skilled officers on the operation of the Act. A house divided against itself, how shall it stand?

MR. STANSFELD'S public excuse for the proved absurdities and omissions of the Public Health Act was sufficiently ingenious, if rather incredible. He aimed at failures, because only by failures in local self-government can success be reached. He claims to have a peculiar insight into the mental and moral constitution of local boards. The result of his experience is a theory that only by realising their own shortcomings, and passing through much tribulation, can they reach the state of docility in which they will be willing to be guided by higher knowledge. After falling often into the mud, they may learn to desire to be supported on the strong wing of the central authority at Gwydyr House. The epidemics of Over-Darwen and Lewes were contemplated in his scheme, and are among the means by which benighted boards may learn to ask for help. His scheme is not one of legislation in the ordinary sense, but of free-will, in which Gwydyr House shall play the part of Providence. The reports which have recently been published of the lay inspectors, each in his own district, are sad examples of the sufferings of intelligent men set to play a part in which they are ignorant of the first principles of their work. The blundering of the authorities is only equalled by the errors of the inspectors; and the simper of self-satisfaction with which this lasting proof of official mismanagement, ignorance, and conceit is put on record, sets the true stamp upon the whole. Here we see a government which feared nothing so much as contact with the men who knew their business, employing the blind to lead the blind, and asking them to record in their own words what is their own opinion of their own proceedings, and carefully abstaining from submitting judgment of a highly skilled expert in their own office, the principal

medical officer of the Board. One day, when we have time and space for a little harmless sanitary fun, we shall take these reports in hand. They are a huge and costly practical joke, but so utterly worthless, except as examples of what to avoid and how not to do the right thing, that just now it were idle to waste more time upon them than we do this week.

ASHANTEE HONOURS.

THE medical officers of the army seem singularly unfortunate in the return which they have received after every campaign, for the skill, care, and attention which they have bestowed upon their combatant brethren while in the field, and at a time when such services are of the very last importance to the latter. As far as we can see, the vast mass of the medical officers engaged on such occasions have received no reward whatever for their untiring devotion to duty, except perhaps a few empty compliments which could scarcely be held back by those in authority. In former days, when the army still retained much of its ancient feudal character and prejudices, and when military surgeons were the nominees of persons of rank against whom it would have been vain to rebel, we could understand the existence of such a state of thralldom; but now that the army has become a national one, and that the interests of the old officers have been bought out at an enormous expense to the country, we fail to see why the young surgeons who enter the service by public competition are denied their fair share in the public honours and rewards, granted no longer to an exclusive class, but to stimulate the military virtues of the whole. It would be vain, indeed, to hope that without such rewards anything but a perfunctory performance of duty would be carried on at a moment when success depends upon the simultaneous and zealous movement of all. In his opening statement, when presenting the army estimates to the House of Commons on the 8th ultimo, Mr. Hardy acknowledged that, with respect to the one expedition which went out last year—that to the Gold Coast—the medical service was so highly satisfactory that it would be wrong in him to pass it by without a word. "I am told by the Director-General of the Army Medical Department that this most satisfactory result, considering the nature of the service and the climate, was mainly owing to the skill, care, and intelligence of the medical officers accompanying the expedition." Yet, in spite of this high eulogium from the Secretary for War, a reference to our Parliamentary intelligence will show that the Horse Guards consider that the medical officers have received their full proportion of honours and rewards in being granted these last in a proportion of one in nine to those engaged, while combatant officers, more than one of whom, we believe, never landed or saw a shot fired, are granted similar recompenses in the proportion of one in three, and this in a doctors' war, when the chief enemy to be combatted was the climate, not the missiles of the Ashantees. Such a want of generosity on the part of the Horse Guards appears to us to be almost without precedent. We cannot but remember that brevet promotions, staff appointments, pecuniary rewards and decorations were sown broadcast among the fortunate soldiers who composed the little army which went to the Gold Coast, and we should have thought that some concessions would have been made to the feelings of those medical officers who bore the brunt of the work, and without whose exertions the confines of the Protectorate would scarcely have been reached. No combatant officer who did good service was forgotten; many medical officers, on the other hand, have but broken health as the legacy of the late expedition. We have commented thus strongly on the injustice of the treatment received upon the part of the profession, and the very unequal distribution of rewards, for we cannot but feel that what is done to-day will be repeated to-morrow, when any similar occasion may arise, unless we continue to do so.

LEPROSY RESEARCHES.

IT will be in the recollection of many of our readers that Dr. Vandyke Carter was commissioned by the India Office to visit, on his way out to India, various places in the East, with the view of gathering information relative to leprosy and allied diseases. A few particulars of his

proceedings may not be without interest. At Milan he saw pellagra, but, contrary to the teaching of books of authority, he could trace no outward resemblance of the disease to leprosy. We are glad to have this opinion, because it relates to a matter in regard to which we have long indulged in scepticism. Dr. Carter visited Biskra, and had an opportunity of seeing the "Biskra bouton". As the result of his observation, it would appear that he gained an impression that the "bouton" is not always specific, at least it seems to pass by many transitions to the form of "boils", yet there are a seasonal and a regional limitation which, when combined, are very significant conditions. At present, Dr. Carter has not made up his mind as to the nature of the disease. At Crete, however, he happened to come across the "Aleppo bouton", which is supposed to be analogous to that of Biskra. The disease was introduced in 1827 from Syria, starting from Cavea; hence the current name of "Cavestica" has spread over the whole island. A cursory inspection of the morbid specimen obtained reveals something like the growth figured by Fleming and others as occurring in Delhi boil, and, as it is contagious, Dr. Carter notices a great likeness between it and Delhi sore, and so far he lends weight to the supposition that Biskra bouton, Delhi sore, and Aleppo boil are one and the same thing in essence, however much they may differ in accidental features. Leprosy, of course, mainly engaged Dr. Carter's attention. He found little or none in Algiers, Tunis, or Greece proper, but plenty in the Archipelago, where the disease is probably spreading and is severe enough. Asylums are provided here and there, but the Turkish Government take literally no trouble about the matter. We believe we are correct in saying that Dr. Carter met with no new observations tending to throw light upon the nature or the cause of leprosy. We are at one with him in being more than ever impressed with the necessity of carrying out a special study of the disease at all stages, and especially in reference to its pathological condition, and in relation with Hansen's recent observations. India, indeed, is *par excellence*, the field for such work, and it ought to be undertaken by competent workers. Sooner or later, facts showing light upon the genius of the disease must be forthcoming to the display of scientific acumen and diligent investigation; meanwhile the segregation of the leper is the most effective and humane *régime* under which the sufferer can be placed, and it offers the best opportunity for affording that alternative which recent observation had shown to be possible. We shall look forward with interest to Dr. Carter's account of the facts he gained on his way to India, and we cannot conclude without expressing a hope that the Indian authorities will give him the opportunity of pursuing his inquiries into the matter of leprosy.

DEATH FROM CHLOROFORM.

THE *Gazette Médicale de Bordeaux* (November 5th, 1874) mentions a fresh case of this kind, a man, aged forty-two, suffering from a canceroid of the penis, on whom Dr. Lande operated by galvano-cautery. Chloroform was given with a compress arranged like a funnel, at the bottom of which was a plug of lint. The patient, though weak, had neither pulmonary nor heart disease. Scarcely had twelve to fifteen grammes of chloroform been inhaled, when, at the end of two or three minutes, the patient became pale, the pulse stopped, the respiration was suspended, and all efforts to restore animation proved fruitless.

ST. THOMAS'S HOSPITAL.

AT a General Court of Governors of St. Thomas's Hospital, held on April 21st, the treasurer informed the Court that the president, Sir John Musgrove, Bart., had founded a scholarship of the annual value of forty guineas, to be awarded biennially in the medical school of that hospital, and to be held for two years by the second year's student placed highest in the first class at the winter examination. Sir John Musgrove, Bart., has transferred the sum of £1,400 Consols into the names of the treasurer and other trustees, and a deed of trust, defining the conditions on which the scholarship is to be awarded and held, has been executed. A very cordial expression of thanks to Sir John Musgrove was unanimously passed.

OBSCENE PUBLICATIONS.

THEY seem to have a much firmer way of dealing with quackery in Scotland, and one which it would be well to imitate a little more on this side of the Tweed. For causing indecent bills to be posted, the principals are fined as well as the bill-stickers. In the Small Debts Court of Glasgow recently, a firm of printers sued a "Dr." Perry of Buchanan Street (whose name does not appear in the *Medical Directory*) for the cost of printing a number of leaflets. The defendant pleaded that the printing was not executed in conformity with his orders, and was of an inferior quality. He produced a copy of the publication to Sheriff Galbraith, who presided, and who, examining it for a minute, said that he declined to look at such a leaflet either in one way or another, and that he could not admit such a disgraceful publication into that Court. He consequently dismissed the action.

THE COTTAGE HOSPITAL, WOODHALL SPA.

IN the spring of 1873, a cottage hospital was opened at Woodhall, in order to place the valuable spa water within the reach of the poor, on terms which they could afford. After the hospital had been in operation for two seasons, it was found that the expense of the baths was so great, that the committee have been obliged to raise the weekly payment for each patient from five shillings to ten shillings. They have also decided that in future a donation of ten guineas, instead of five, shall be requisite to constitute a life governor, and have appealed to their supporters, begging them, in the interests of the hospital, either to refrain from exercising their right of nomination or to increase their subscriptions. The treasurer announces in the third annual report, recently published, that his appeal has been responded to in a liberal spirit, and he hopes that the hospital will re-open this spring free from debt. We are glad that this institution has thus been placed upon a basis which promises to give it permanence. We have more than once pointed out the value of the Woodhall waters. The large proportion of iodine and bromine which they contain—a larger proportion than any other mineral water in the world—makes them particularly valuable in all cases that are connected with the scrofulous diathesis. A brief statistical table, appended to the report by the medical officer, Mr. R. Cuffe, shows the classes of cases that are most likely to derive benefit from a visit to Woodhall.

THE PHYLLXERA.

ACCORDING to Reuter, the Academy of Science of Paris have discovered an effectual and practical means of destroying the phyllxera. The Academy will shortly publish a communication on the subject, and it is believed that this plague will be averted.

THE LATE PROFESSOR OPOLZER.

A PORTRAIT of the late Professor Opolzer was publicly unveiled in the large hall of the Academy of Sciences in Vienna, on April 17th, in the presence of a large concourse of professors, students, medical practitioners, and others. Addresses were delivered by Herr Waller on the part of the students, and by Professor Zimmermann. Dr. Theodor Opolzer, professor of Astronomy, returned thanks for the honour paid to the memory of his father.

LEEUWENHOEK AND THE MICROSCOPE.

A COMMITTEE has been formed at Delft in Holland, to make arrangements for the celebration, on September 8th, of the second centenary anniversary of the discovery of microscopic animals by the celebrated Antony van Leeuwenhoek, a native of the town. It is intended to render the occasion especially interesting by the exhibition of the microscopes which the distinguished naturalist made and left at his death, and of letters and other memorials of him. The Committee are also endeavouring to raise a fund for the purpose of founding a gold medal, to be awarded under the name of the Leeuwenhoek medal, every tenth year, to the Dutchman or foreigner who shall have done most for the advancement of microscopic science. The award is to be made by the Royal Academy of Sciences at Amsterdam.

THE RISKS OF OBSTETRICIANS.

IT is not long since an action was brought against a medical man, and heavy damages consented to, for having accidentally infected his patient with syphilis whilst attending her at her confinement. The case created much attention at the time, from its extreme rarity and the attendant circumstances. The reverse, we believe, has never happened, where the attendant has sued the patient for infecting him, although this is of much more frequent occurrence, and the ultimate consequences more serious. Many practitioners have not only been ruined in health, but even in reputation and character, through this untoward accident. In some cases that have come to our knowledge, the persons were advanced in years, the effects of the syphilitic poison most severe, and ruinous in their consequences. The legislature has been very careful to protect the public from the effects of negligence or malpractice on the part of the practitioner; but is the reverse the case? The question comes, how to obtain security against the liability of contagion, and redress, after being infected. Dr. Cairns, who brought a most interesting but sad case before the Obstetrical Society of Edinburgh in November last, where a medical man was doomed to suffer most grievous wrong, lose his best patients, have his character assailed and maligned, and his very presence shunned, through having caught syphilis whilst attending a gratuitous patient, suggests that patients should be compelled by pains and penalties to inform the attendant, when about to be confined, that they are suffering from venereal disease; and that, in every case where there is any abrasion of the skin of the hand, the medical man should use a gutta-percha covering, if he be not ambidexter; and that he should carefully wash the hand afterwards with a good antiseptic. Respecting the former proposal—that patients should be compelled to acquaint the attendant that they are suffering from venereal disease—it is open to this very grave objection and serious difficulty: the majority of women who have contracted syphilis from their husbands are entirely ignorant of the fact; and, again, many women give birth to syphilitic children without themselves being affected, apparently, in the least degree, and yet their children may be the source of contagion to the medical man. The subject is one of extreme difficulty, and worthy of serious consideration.

DEATH DURING THE ADMINISTRATION OF ETHER.

WE are favoured by Dr. James Hardie of Manchester, with the following particulars of the case of fatal administration of ether, which has recently occurred under his care. J. F., a delicate timid boy, aged 16, had long suffered from strumous disease of the bones of the feet. He became an inmate of the Manchester Workhouse Infirmary last autumn. On September 25th last, Dr. Hardie removed the right foot at the ankle-joint, chloroform being administered. He bore the anæsthetic well. On October 29th, the cuboid bone of the left foot and the metacarpal bone of the left thumb were excised. On this occasion chloroform was again administered. When the operations had been completed, some alarming symptoms showed themselves, viz., fixed dilated pupils, feebleness of pulse, extreme pallor, and absence of respiration. These quickly passed off, on the tongue being forcibly drawn forward, cold water sprinkled over the face, and galvanism applied to the phrenic nerves. On the 3rd of the present month, bare bone having been found to remain in the unhealed wound of the thumb, the boy was again placed on the operating table, having previously been given an ounce of brandy. He was asked to have the trifling operation performed without an anæsthetic, in order to test his probable endurance; but, the patient beginning to whimper, Dr. Hardie stirred a probe about in the wound. This caused him to cry out; and ether was administered by Dr. Hardie, who poured about four drachms on a piece of lint, which was placed in a folded towel, and held pretty closely over the face. He inhaled the vapour more quickly than usual, there being no coughing, and but little struggling. In about four minutes from the commencement of the inhalation, and before any fresh ether was poured on the lint, he was apparently ready for the operation. Immediately afterwards, before the operation was begun, Dr. Hardie observed the

respiration, which he had been closely watching, suddenly cease; and, at the same instant, an extreme pallor came over the face, and the pupils became widely dilated. At the moment when these symptoms appeared, he had not his finger on the pulse, nor did he feel for it before resorting to remedial measures. Mr. Pountney, the house-surgeon, however, on placing his finger over the radial artery, when Dr. Hardie gave the alarm, found it to be imperceptible. Dr. Hardie immediately pulled the tongue forcibly forward, but without effect. The poles of a battery standing in readiness were then applied to the phrenic nerves, and only induced three or four gasping attempts at respiration, which also then ceased. Cold water affusion, artificial respiration, and Nélaton's method of suspension by the feet, were all successively had recourse to, without the slightest avail. Indeed, beyond the few gasps induced by the application of the battery, there was not the smallest response to the efforts towards reanimation. After twenty minutes, these were discontinued. The *post mortem* examination was made, by the Coroner's order, by Mr. J. Armstrong. The following is the report in the hospital register of inspections, by Mr. Needham, senior house-surgeon, who was present. The brain, larynx, liver, kidneys, and intestines were healthy. The stomach was quite empty, and no signs were observed of any attempt to vomit. The cavities of the heart were quite empty, and the lungs were neither gorged with blood nor darker than usual; their posterior portion was somewhat dark, but this was probably owing to the position of the body on its back. The spleen showed commencing amyloid degeneration. The larger blood-vessels contained much blood, which was very dark, and showed no tendency to form clots, but seemed loose and fluid. No microscopic examination of the heart was made, but to the naked eye it appeared healthy, only being slightly pale. It appears probable that death resulted from syncope. The ether used was Robbins' ether for local anæsthesia.

OTHELLO AND HAMLET.

THE performance of the part of Othello by Signor Salvini at Drury Lane is one of the most interesting of psychological studies. Of all the great life-histories which our national dramatist has bequeathed as an immortal legacy to our literature, there is none more strongly and nobly marked than this of Othello. Less subtle, less varied, and less changeable than that of Hamlet, always a favourite study of psychologists, it is yet more splendid in its passion, and more pathetic in its motives. Both passion and pathos find in Salvini an interpreter rich in natural gifts of voice and person, and whose histrionic power is so developed by study and so strong in genius, that this difficult character is here realised with singular grandeur and startling effect. The sudden changes in mood, the gradual alienation of mind, the highly wrought accessions of rage, the melting moments of pity, the distracting anguish of horrible suspicions and false beliefs, and the tiger-like impulses of the ferocious jealousy of the hot-blooded Moor, are rendered by Salvini with marvellous power. It is curious to observe how Shakespeare, whose observation ranged so widely, had taken note of the association of epileptiform seizures with brutal accessions of rage, on which alienists have much dwelt of late; and the wildest rage of Othello is associated with "trance". The stage is so degraded with buffooneries and burlesques, made up of jingle, fleshings, and poor verbal jests, that the advent of an artist such as Salvini, who restores it to its true function, is worthy of record. Mr. Irving's performance of Hamlet might perhaps here also properly be mentioned, but that we think that the actor has misconceived the psychological import of the character. The fussy, vulgar, spasmodic, ranting, gasping prince, in whom Mr. Irving, by much study and great skill, interests us, in spite of our better judgment, is not the noble, high-bred, philosophic Prince of Denmark whom Shakespeare shows us in the closet. His madness is a piece of player's fustian: we seem all the time to be present at another version of "The Bells". It is an effective and studied performance, but no true picture of that most interesting and most noble of Shakespearian characters.

MEDICAL WITNESSES IN THE POLICE-COURTS.

DR. CORBY, House-Surgeon of the South Infirmary, Cork, and his resident pupil Mr. Fahil, have, as we learn from the *Cork Examiner* of the 17th ult., done good service by calling attention to the anomalous position of medical men who are required to give evidence before magistrates. A patient had, in a quarrel, received a cut on the head, which was dressed at the Infirmary. Mr. Fahil, who was summoned to give evidence at the police-court, respectfully objected to make any statement unless he received a fee for his attendance. This course he adopted at the request of Dr. Corby; and the latter gentleman said: "We object on principle, because, if we were compelled to give evidence in the case of every cut we dress at the Infirmary, we would soon have no time at our disposal to attend accidents at all, and, in fact, a second house-surgeon would be needed." The magistrates, the chief clerk, and two solicitors concerned in the case were all of opinion that the medical witnesses ought to be paid for their attendance; but unfortunately the magistrate has no power to allow fees in such a case as this, nor is there any fund out of which he could pay them. We sadly need a new Judicature Bill, which, while it does not overlook weightier matters, will condescend to provide for the reasonable remuneration of medical witnesses in the inferior no less than in the superior courts of law.

ALLEGED NEGLIGENCE BY A MEDICAL MAN AT BOSTON.

THE *Lincolnshire Herald* contains a report of the prosecution of a medical practitioner of Boston, Lincolnshire, for causing the death of a midwifery patient by mismanagement and neglect. As the defendant thought proper to reserve his defence, we can only give the facts as they appear from the evidence of the prosecution. From this it appears that the doctor was called to visit the patient, a multipara, about 7 a.m. He went at once, found that she had been in labour about five hours, and that she was in a very exhausted state, owing to hæmorrhage, which had been going on for some time. Having administered some brandy, he immediately proceeded to deliver by turning. The witnesses for the prosecution allege that he used considerable force in performing this operation, and that the delivery was effected with undue haste. They also state, however, that the child, a seven months' fetus, and the afterbirth, came away together, and it appears likely that the case may have been one of placenta prævia, with breech-presentation. But little blood was lost during or after the birth, and, as the patient appeared comfortable, the doctor soon took his leave. About an hour afterwards, sudden collapse occurred, and the patient sank rapidly. At the *post mortem* examination, a rupture of the uterus was found. As the defendant was committed for trial, this is not the time to comment on the case. We are, however, sorry to read the very positive way in which one of the medical witnesses criticised the defendant's conduct. We only hope that he himself may never be placed in a similar position; though, if the report above referred to be a fair one, much more unlikely things may happen.

SCOTLAND.

THE conferring of medical degrees took place at Aberdeen University on Saturday. Twenty candidates received the M.D. degree, and thirty-one that of M.B. The address to the graduates was delivered by Dr. Ogston.

THE installation of Dr. Alleyne Nicholson to the Chair of Natural History in the University of St. Andrew's, vacant by the death of the late Dr. Macdonald, took place last week in the Lodge Hall of the United College. On the 22nd, the graduation ceremonial of the same University occurred, when nine candidates were presented for the degree of M.D.

At the second professional examination in Edinburgh, held last week, the inspectors of the General Medical Council, Dr. Barclay of St. George's Hospital and Professor Humphry of Cambridge were present and inspected the examinations.

DR. BELL PETTIGREW, Lecturer on Physiology at Surgeons' Hall, Edinburgh, has been awarded the Godard Prize of the French Academy of Sciences for his original anatomical and physiological memoirs. In virtue of this distinction, Dr. Pettigrew becomes a Laureate of the Institute of France.

WEDNESDAY, April 21st, was the Graduation Day in the University of Edinburgh, for the arts and other classes at the end of the winter's work. Among other degrees conferred was that of D.Sc. on Mr. T. B. Belfour, with first-class honours; of B.Sc. in the new department of Public Health, with first-class honours, on Mr. James A. Russell, demonstrator of anatomy, the first degree of the kind in this department; and two of M.B. and C.M. After the ceremony, an address was delivered by Professor Sellar, in which he contravened the arguments used by the Principal at the beginning of the session, derogatory to the arts teaching in the university, and showed that, since 1858, there has been a gradual and very considerable increase in the number of arts students, and now this is crowned by the largest number of arts graduates on record.

ACCIDENTAL POISONING.

A CASE of accidental poisoning took place at Barnhill, Perth, on Saturday. A few months ago, a man named Robertson had one of his legs amputated in the Perth Infirmary, in consequence of a railway accident. He did well, and a short time since was allowed to return to his own house, where he was attended to by his wife. On Saturday afternoon, Mrs. Robertson gave her husband what she thought was the tonic he was in the habit of taking, but unfortunately she had taken the wrong bottle, and, instead of the tonic, administered a quantity of the liniment used to his leg, in consequence of which he died in about two hours.

THE EDINBURGH ROYAL INFIRMARY ACT OF PARLIAMENT.

WE are informed that the expenses of passing the Act of Parliament just obtained by the managers of the Royal Infirmary will be defrayed with a sum of money given for the purpose by the trustees of the late Mr. David Nisbet, architect, Edinburgh. In this way, the ordinary funds of the institution will be relieved of a considerable burden.

MILK IN EDINBURGH.

At a late meeting of the Edinburgh Town Council, the report of the city analyst, Dr. Falconer King, for the past quarter was read. During that time, six samples of milk had been sent in for analysis, of which only one was found adulterated, and that was by being mixed with a considerable quantity of skimmed milk. The report stated that considerable alarm had lately been caused by a rumour that the common flavouring substance oil of lemons was largely contaminated with lead. A sample of the substance was subjected to a careful analysis, with the result of showing that only the merest trace of lead was present.

THE HEALTH OF EDINBURGH.

THE report of the Medical Officer of Health for Edinburgh, for the month of March, shows that the mortality during that month was at the rate of 26 per 1,000 of estimated population. This comparatively high mortality is accounted for by the unusual number of deaths from diseases of the respiratory organs. Meanwhile the health of the city, so far as diseases of an infectious nature are concerned, is very satisfactory. During the past month only three deaths from fever have been recorded—indeed a fortnight elapsed without a death from fever of any kind being registered—a very unusual event in Edinburgh. The corresponding month of last year shows a lower death-rate on the whole (24 per 1,000), but a much higher mortality from fever. This year the mortality is spread pretty equally over the old town, new town, and

southern suburbs—a fact which indicates the action of no merely local cause, but the question of a low and uncertain temperature affecting the whole city.

ANCIENT REMAINS.

At the monthly meeting of the Society of Antiquities of Scotland, an interesting account was given by Mr. A. J. Warden, of the opening of several stone cists, containing human remains and urns, at Barnhill Links, in the parish of Monfeth. One of the skeletons had been the subject of more than usual interest, on account of a curious appearance on the long bones, which seem to have been bound round closely and regularly with some fibrous substance, suggestive of decayed strands of hemp. But Mr. Sadler, assistant to the professor of botany, stated that the structure exhibited under the microscope, by the great mass of the vegetable matter, was not fibrous in texture, but composed of rhizomorphic fungi—a curious class of plants, which grow in cists and coffins, and sometimes entirely fill them. A curious and interesting collection of stone implements from Shetland, and a nugget of native gold, weighing close upon an ounce, from Kildonan, Sutherlandshire, were exhibited at the same meeting. The gold nugget is said to be the largest ever found, except one in the possession of the Duke of Sutherland.

THE PROPOSED REGISTRATION OF FOREIGN DEGREES FOR WOMEN.

THE Royal College of Surgeons of Edinburgh has forwarded to Dr. Lyon Playfair a petition against the Bill now before Parliament "To amend the Medical Act, 1858, so far as relates to women who have taken the degree of Medicine in a foreign university"; the universities specified being those of France, Berlin, Leipzig, Berne, and Zürich. The petitioners admit that it might be a fair question whether the degrees of certain foreign and colonial universities of good repute should be allowed to be registered, the privilege, however, not being confined to women; but they point out that it should be left to the General Medical Council to decide, after due inquiry, what universities should be so registered. They further allege that, without such provision, it would be unfair to the public and the profession of Britain to admit to registration foreign and colonial degrees, which are beyond the supervision of the Medical Council. A further objection urged is, that to pass such a measure as the Bill in question would be inexpedient and partial legislation, and inconsistent with the object of the Medical Act.

IRELAND.

ROYAL COLLEGE OF SURGEONS OF IRELAND.

ON Tuesday, May 4th, pursuant to the provisions of the Supplemental Charter, the election for the various examiners of this college will take place. These include seven examiners to examine candidates for fellowship and letters testimonial; three for the diploma in midwifery, and a similar number to examine students as to their proficiency in general education. A considerable amount of interest is expected for these elections, as several names, some already on the council, intend, it is said, to compete for these appointments.

CONVERSAZIONE AT THE ROYAL COLLEGE OF SURGEONS OF IRELAND.

ON Thursday evening, the 15th instant, the President and Council of the College of Surgeons entertained his Grace the Lord-Lieutenant and a numerous company at a *conversazione*. All the rooms in the College were thrown open, and a military band attended, and performed at intervals during the evening. A large number of interesting scientific and artistic objects were exhibited. His Grace arrived about ten o'clock, and was conducted through the rooms by the President. The arrangements were excellent, and reflected great credit upon the organisers of the entertainment. We were glad to notice among the visitors a large number of non-professional gentlemen. We think that

such entertainments are well calculated to bring the public into more intimate relations with our profession, and should always be glad to welcome a larger proportion of the non-medical element in such assemblies. We congratulate the President and Council on having their invitations responded to by such a varied company, and upon the excellent arrangements for their entertainment.

PATHOLOGICAL SOCIETY OF DUBLIN.

THE last meeting for the session was held last Saturday. It is customary for the president to declare the name of the winner of the gold medal of the Society, for the best essay on the subject named by the Council for competition among the students who attend the meetings. The subject for this year was on the "Human Entozoa", but, no essays having been sent in, no medal was awarded.

SPECIAL CORRESPONDENCE.

PARIS.

[FROM OUR OWN CORRESPONDENT.]

Paris, April 11th, 1875.

Effects of Atmospheric Pressure on the Blood.—*Germs and Ferments.*—*Dr. Dechambre and the Academy of Medicine.*—*Professor Pajot.*—*Professor Gubler.*—*Concours for Appointment of Professor Agrégé.*—*The General Medical Association of France.*

YOUR readers are doubtless acquainted with the researches of M. Bert, with reference to the quantity of oxygen which the arterial blood of animals contained at different degrees of atmospheric pressure. He has instituted further inquiries in order to ascertain the amount of oxygen the blood is capable of absorbing at divers degrees of barometrical pressure. In a paper read before the Academy of Sciences, he has summed up the results of his experiments as follows: "There exists a combination of oxygen with hæmoglobin, which may be obtained by agitating blood and air at the normal pressure. This combination remains stable at a temperature of 16 deg. C. (60.8 deg. Fahr.), under gradually diminishing pressure, until it reaches about an eighth of the atmosphere; but at the temperature of the bodies of the mammalia, the combination becomes gradually dissociated according as the pressure diminishes." From these experiments the following deduction may be made, viz.: That the poverty of the blood in oxygen of an animal placed under feeble pressure depends on the imperfect union of the air with the blood in the lungs, and the diminished capacity of the blood for absorbing oxygen, so that, if it were possible to saturate the blood of the animal with oxygen under such pressure, the quantity of oxygen would still be considerably less than the blood would contain at the normal pressure. In other words, the anoxyhæmia which produces mountain-sickness is brought about by purely physico-chemical and physiological processes.

The discussion about germs and ferments is still going on at the Academy of Medicine. After passing in review M. Pasteur's opinions about putrid fermentation in eggs and fruit, and the production of ammoniacal urine, M. Colin stated that, "in making a synthesis of the facts observed, one is led to think that the ammoniacal salts, such as urea, etc., can be found at divers parts of the organism: that they then enter the general circulation, and are finally eliminated by the kidneys, and the other excretory organs". What makes him believe that the ammoniacal products do not originate in the bladder, is the fact that he had not been able to produce ammoniacal fermentation, notwithstanding he had placed the animals for experimentation in the most favourable position for the production of such a phenomenon. For instance, M. Colin injected into the bladder of a cow twenty-five cubic centimetres of putrefied urine, and, notwithstanding this, the cow continued to void normal urine. In summing up his arguments, M. Colin advised that we should not be too hasty in coming to conclusions, or in accepting as absolute and definite solutions of difficult problems; doubts and objections provoke researches which lead to the discovery of new facts, new relations, new laws. The study of fermentation in the living organism and the dead body is incomplete. M. Pasteur considers M. Colin's experiment with ammoniacal urine of no great value. Why should it astonish, he said, that putrefied urine should not have rendered the cow's urine ammoniacal? If the animal expelled the liquid immedi-

ately it was injected, the vibriones, not having remained in the bladder, could not change the nature of the urine.

Dr. Dechambre, the talented editor of the *Gazette Hebdomadaire*, and author of several works, has been elected a member of the Academy of Medicine. The tardy recognition of the meritorious services of a man so well known was the wonder of all who knew him; but the Academy has somewhat redeemed its fault by acting on the principle of "better late than never".

The opening of the School of Medicine took place on March 15th. Professor Pajot began his course of lectures on the following day. I need hardly say that his reappearance at the school was looked forward to with the greatest impatience, and long before the hour the amphitheatre was crowded. The spectacle was very imposing, and offered a great contrast with the "manifestations" reserved for unpopular professors. When he entered the amphitheatre, the scene was most affecting. He was received with an outburst and a salvo of cheering; and he was so overwhelmed by this mark of affectionate sympathy that it was some minutes before he could speak. He then addressed the students in the following terms. "Gentlemen, it seemed to me that, after the fatigue caused by overwork, and after having been engaged in teaching for thirty years, I was entitled to rest, and that I should yield my place to younger heads and hands; but it seems it must be otherwise. You think I am still good for something, and, although I am not altogether of your opinion, I found I had no alternative in compliance with your own solicitations but to return to my post; so here I am. In former years, I had not to ask your indulgence, I did not require it; but now, age and sickness render this necessary. It is not with impunity that one can practise the profession of accoucheur, which requires him to spend night after night without any sleep, and, at the same time, speak for an hour nearly every day, in a large amphitheatre like this, for thirty years. One must have the constitution of a horse to be able to withstand for any time the mental and physical fatigue inseparable from such a profession. So you see, strong as I was, I have at last broken down, and now require rest. I shall, however, do my utmost to continue my work, that is, if my health will allow me, so let us not lose a moment." These words were received with great applause; and on silence being restored, the professor continued: "Gentlemen, now that we have offered mutual felicitations, let us work." I cannot help thinking that these demonstrations are of questionable propriety, and it must be galling, I should say insulting, to unpopular professors that their pupils should be allowed to sit in judgment on them, especially if their unpopularity arise, as indeed it almost always does in the Paris faculty at least, from some difference of political or religious creed between the two parties.

Professor Gubler, another popular lecturer at the School of Medicine, devoted his first lecture for the session in simply recapitulating last year's course on the therapeutics of acute diseases. M. Gubler first treats of the diseases, and then enters into the natural history of the therapeutic agents employed, which gives the student a better notion as to their clinical application. This year, M. Gubler is to take up the treatment of chronic affections, and he places first on the list the different forms of dyspepsia, which is found associated with almost all chronic affections, either as an efficient cause or complication, and which is often an indication of the first stage of cachexia. Then follow the various degrees of anemia and nervous affections, which are frequently superadded to the above. He next proposes to treat of the different forms of cachexia, gout, Bright's disease, diabetes, and the treatment of two opposite conditions of the system, emaciation and excessive fat.

These lectures were interrupted by the competition examinations, or *concours*, for the appointment of professor *agrégé*, or subprofessorship in medicine, which has just been brought to a close. The following are the successful candidates: MM. Dieulafoy (well known in connection with the aspirator), Grancher, Lionville, Lépine, and Legroux for Paris; and MM. Grasset and Ballestre for Montpellier; all distinguished for their works in the various branches of medicine.

The annual meeting of the Association Générale des Médecins de France, a benevolent society, took place on Sunday, April 4th, and was followed by the usual banquet. As the funds of this Association are in a prosperous condition, the annuities have been extended to the families of deceased medical men who may be in need; and it is in contemplation that, should the funds continue to prosper, pensions will be granted to all medical men who may belong to the Society. The chair was occupied by M. Tardieu, the President; but M. Amédée Latour, the talented and well-known Editor of the *Union Médicale*, though present at the meeting, was prevented by indisposition from occupying his usual seat of General Secretary. He was replaced by M. Brouardel, who read the annual report.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 22ND, 1875.

SIR JAMES PAGET, Bart., D.C.L., LL.D., F.R.S., President,
in the Chair.

PRACTICAL OBSERVATIONS ON THE PULMONARY AND CARDIAC COMPLICATIONS OF ABDOMINAL TUMOURS: WITH REMARKS ON BLOOD-LETTING AFTER SURGICAL OPERATIONS. BY WILLIAM HENRY DAY, M.D., M.R.C.P.

THE author first described some of the effects of solid or cystic abdominal tumours, and of large collections of fluid in the peritoneal cavity, in displacing the thoracic organs, and inducing a long series of constitutional and local symptoms. He showed the importance of ascertaining the condition of the lungs and heart before deciding upon the removal of fluid or of tumours from the abdominal cavity. He examined the effects of rapid and of gradually increasing pressure upon the thorax, and also the results of the rapid removal of pressure by tapping or by the removal of a tumour; advocating the gradual removal of pressure whenever practicable, and giving several instances to prove the utility of venesection in cases where portions of lung which had been compressed have rapidly expanded, and congestions or hepatisation have followed. He also gave instances in which organic diseases of the lung have been relieved after the pressure which aggravated the symptoms had been removed. He compared the pulmonary symptoms which often follow operation on the abdomen with the more ordinary forms of bronchitis or pneumonia, and gave practical details of treatment in different classes of cases. The author ended his paper by endeavouring to enforce the two following conclusions. 1. The surgeon who treats cases of abdominal distension must not overlook the pulmonary and cardiac complications which are due to compression or displacement. 2. The success of operations for the removal of abdominal tumours may be increased or diminished by careful examination of the state of the chest before operation, and by equally careful attention after the operation, not only to the parts involved in the surgical proceedings, but also to those changes in the blood and in its circulation through the heart and lungs, and to the effects on these organs, which are due to sudden removal of pressure alone, or to other causes of considerable elevation in the temperature of the blood.

MR. KNOWSLY THORNTON had seen much of the cases referred to in the paper; they seemed to bear out the author's remarks on blood-letting. There were two important questions to be considered. When should blood-letting be performed? and in what class of cases? He thought that it should be done promptly, when the first symptoms appeared—flushing of the face, with rapid pulse and hot dry skin—even though there was yet no rise of temperature. If this period were allowed to pass, blood-letting did not seem to act so readily. The application of cold to the head was very useful in many cases, in which there appeared to be a condition of brain which led to a rise of temperature and rapid pulse. For this purpose, he recommended the cap (or a modification of it) used by Mr. Lister, by which a constant stream of water was constantly poured over the head. Under the application of cold to the head, symptoms of acute bronchitis sometimes rapidly ceased. The action was too rapid to be accounted for by cooling of the blood; it seemed as if some influence were exerted directly on the brain. This method was preferable to the cold pack in hyperpyrexia, while in septicaemia the latter was especially indicated. —DR. FROTHROCK SMITH had for many years practised venesection in connection with ovariotomy, in preparing patients for the operation. He removed small quantities of blood. —MR. SPENCER WILLS doubted whether small bleedings before the operation would have much influence on the result. He rather agreed with Mr. Thornton that, when it was necessary to bleed after ovariotomy, the bleeding should be early and free. Since Dr. Day's paper was written, he had had four or five cases in which bleeding was followed by remarkable relief. He could also bear testimony to the usefulness of the ice-cap, which had the advantage over the cold pack that the patient was not disturbed. He had lately given small and repeated doses of aconite—half a drop of the pharmacopœial tincture every half-hour—with the effect of quickly rendering the pulse slower. The effect on temperature was less marked. —DR. DAY, in reply, pointed out that blood-letting was

not always at once followed by a fall of temperature. The ice-cap was no doubt useful in many cases; but sometimes it failed in relieving the symptoms.

A CASE OF LEFT SUBCLAVIAN ANEURISM TREATED BY TEMPORARY COMPRESSION APPLIED DIRECTLY TO THE ARTERY IN THE FIRST PART OF ITS COURSE. BY ARTHUR FERGUSSON M'GILL, F.R.C.S., LEEDS.

(Communicated by JOHN WOOD, F.R.S.)

THE patient, a laundress aged 35, had been suffering from an aneurism of the third part of the left subclavian artery for three years. She had been treated by digital compression, by manipulation, and by repeated galvanopuncture. The first two methods were adopted without result; the last with great, though temporary improvement. In December 1874, it was found, on examination, that the pulsation extended upwards from the centre of the clavicle for $1\frac{1}{4}$ inches, and downwards and outwards from the same spot for $2\frac{1}{2}$ inches. The patient was suffering much from pain; her rest was impaired; and she was rapidly becoming worse. Under these circumstances, it was determined to try the effect of temporary compression applied directly to the artery at the first part of its course. On January 2nd, 1875, the operation was performed. An incision was made from the centre of the sternum upwards along the anterior border of the sterno-mastoid for two inches, and another of the same length along the clavicle; the sternal and part of the clavicular origin of the sterno-mastoid muscle was then divided, and the anterior scalenus and first rib were reached. After searching with the finger, the artery was found displaced backwards, and an aneurism-needle was passed round it. In passing the needle, a small opening was made in the pleura. The artery being isolated from the surrounding structures, a pair of torsion-forceps were applied, and left on for ten hours and a half. The next day, there was a return of pulsation in the sac; but this disappeared in twelve hours. She was apparently doing well, when symptoms of pleurisy and bronchitis supervened, and she died at the end of five and a half days. Leave could not be obtained to make a complete *post mortem* examination, but a partial examination at the seat of the operation was allowed. The forceps had been applied at the point where the vertebral was given off, and at that position the artery was patent and healthy. The aneurism, which commenced a quarter of an inch from the thyroid axis, and extended outwards for $3\frac{1}{4}$ inches, was filled with a hard clot, and was in fact cured. The operation was only performed after grave consideration. It was thought, (1) that no other method of treatment could be adopted with advantage, (2) that the proposed operation was practicable, and (3) that there was a reasonable prospect of success. The second of these opinions was arrived at after making many dissections on the dead body, and after learning that Dr. Rodgers of New York had applied a ligature to the subclavian artery in this position. It was thought that the application of a ligature in the ordinary manner was unjustifiable, as experience showed that patients on whom this operation was performed almost invariably died of secondary hæmorrhage. It was hoped that, by applying temporary compression, this accident would be avoided; while the experience of the rapid-pressure treatment of aneurism, introduced by Dr. W. Murray, showed that a cure by this procedure was not improbable. When this method of treatment was adopted, the cure was not effected by the gradual deposition of layers of fibrine, but by the sudden coagulation of the contents of the sac. This would account for the return of the pulsation on the second day after the operation. Though in this case the treatment had not been successful, it seemed probable that it might hereafter prove so in similar cases.

MR. JOHN WOOD said that the application of direct pressure to an artery was very different from pressure from without; it was difficult to regulate the force applied so as to avoid sloughing of the vessel. He thanked Mr. McGill for bringing forward the case; there was too much reluctance to make unsuccessful cases public. —MR. HENRY LEE said that the filling of an aneurismal sac with clot was not the same thing as curing the aneurism. He had had a case of inguinal aneurism which he treated by flexion. A clot formed; but the patient would not keep his limb bent, and the clot disappeared in two or three days. This was followed by intense and long continued pain in the course of the femoral artery, as if portions of the clot had been washed down the vessel. —MR. HYLKE said that Scarpa had used a broad ligature for the purpose of occluding arteries without dividing the middle and internal coats. —SIR JAMES PAGET called attention to the method recommended by Mr. John Dix of Hull, of using wire, bringing out the ends through the skin apart from the wound, and twisting them over cork, so that the ligature could be tightened or loosened at pleasure. —MR. MCGILL said that the pressure was applied as lightly as possible, so as to avoid division of the inner and middle coats of the vessel.

CLINICAL SOCIETY OF LONDON.

FRIDAY, APRIL 23RD, 1875.

E. HEADLAM GREENHOW, M.D., F.R.S., Treasurer, in the Chair.

Fibroma.—Dr. TILBURY FOX communicated for Dr. Gustavus Fritzsche of Poland a case of fibroma weighing thirty-five pounds, which was successfully removed. The case occurred in the surgical clinical establishment at Warsaw, and was operated upon by Dr. Kosinski in that hospital. The patient, a female aged 27, stated that the growth had existed from childhood, and in all probability was congenital, as directly after birth a little dark spot was observed in the position of the subsequent growth. It increased slowly, and assumed great dimensions, so that the patient could not stand long, could not lie on her back, and could not work. Three years before admission, she observed a sore place on the lowest part of the growth; and there escaped from it an enormous quantity of serous fluid. When admitted, the patient was seen to be of medium stature and weakly constitution. Her skin was pale, rough, and covered with a great number of dark brown spots, especially on the extremities. In the sacro-lumbar region was a large tumour hanging to the knees of the patient when she was in the erect position. The pedicle of the tumour extended from the eleventh dorsal vertebra to the junction of the sacrum to the coccyx, and on the sides to lines drawn perpendicular from the ends of the eleventh ribs. The skin covering the growth was of a brown colour, and was very thick. At its lower part were numerous enormously enlarged lymphatic vessels in and under the skin. The whole mass was very soft, and felt like a bag filled with a gelatinous mass. The tumour was removed by a circular incision made round the pedicle; and afterwards, by a few deep cuts, the mass was separated from the body. A large quantity of blood was lost; and the patient, after the operation, was very weak and exhausted. The healing of the wound, which was retarded by an attack of erysipelas, occupied six months. The growth weighed thirty-three pounds, without the fluid and blood which escaped during the operation, and which would have weighed at least two pounds. Microscopic examination of the tumour showed that it consisted of long bundles of cellular tissue, which was in some places very loose. These bundles contained many spindle-cells, and formed a network, the meshes of which contained much fluid, with a great percentage of albumen and many wandering cells. At the end of six months, the patient left the hospital in good health and much strengthened.

Dr. TILBURY FOX said this was a valuable contribution to the therapeutics of fibroma; for, taken in connection with Mr. Pollock's cases, it showed that such large masses could be removed successfully, contrary to what is stated in books.—Mr. POLLOCK said that, in all the cases he had seen (ten or twelve), there had been smaller multiple tumours in addition to a larger mass. He pointed out the necessity of trying to save as much blood as possible during the operation; this was done in his last case by first passing numerous ligatures round the base of the mass to be removed, the vessels being so large, that the veins equalled the fingers in size, while the arteries were as large as the radial. Although he left much behind, yet the mass removed was so great (extending the whole length of the thigh), and, in spite of precautions, so much fluid and blood was lost, that the patient never rallied from the operation.

Disordered Nerve-Function in an Infant.—Mr. THOMAS SMITH related the following case. L. C., a girl sixteen months old, the only child of healthy middle-aged parents, was under the care of Dr. Chalkdcott of Chertsey. She was healthy up to a year old, when she could walk. At this time, she began to cut her teeth rapidly, and suffered from disordered bowels, being for the most part troubled by obstinate constipation, but occasionally suffering from diarrhoea. Her urine became high-coloured and very offensive. She gradually lost strength, became unable to walk, and finally was too feeble even to sit up. She had no convulsions. When first seen by Mr. Smith, she had been ill for four months; her expression was anxious; face pallid; she was very irritable; she could neither sit nor stand. The skin was everywhere harsh and dry; on the front of the belly, it was shrivelled, and looked as if she had borne children. The pulse, tongue, and respiration were natural; the bowels, though obstinately constipated, were less so than heretofore. There was scarcely any hair on the head. She held her hands to her head like a child suffering from cervical caries. There was tenderness over the spine in the sacral region. There was no paralysis of sensation or motion. The urine and feces were normally retained. The following phenomena were observed. The child, who was extremely fretful and irritable, could at once be quieted by scratching roughly either the palms of the hands or soles of the feet. If this

were done, she at once became quiet; the expression of her face completely changed; her muscles relaxed; and in a minute or two the parts scratched lost their dry and horny condition, and became warm and soft. Meantime, perspiration began to flow most profusely, until it dripped from the surface. The parents said that, as long as this irritation was continued, the same phenomena were observable; and that the child would remain quiet even for hours. The same results could be obtained by scratching the scalp, or by plucking out the hair. The present hairless condition of the head was due to the child having torn off her own hair for her own pleasure. She had been treated with advantage by bromide of potassium and hydrocyanic acid, and her constipation had been relieved by small doses of jalapin with podophyllin. Two months later, under the continuance of the same treatment, all symptoms, with the exception of the constipation, had disappeared. The urine was normal; the skin moist and soft; the palms and soles were no longer dry and horny, and she could not bear to have them touched. The hair was growing well on the head: she had no pain; she could sit up, and even walk. The improvement had been gradual and persistent. Mr. Smith brought this case before the Society as an instance of that form of hysteria known as spinal irritation, and fully described by Dr. Radcliffe, the late Dr. Anstie, and others: a disease seen, as he said, too frequently in adults, especially in the middle and upper classes, but most rarely met with in infants.

Scald of the Glottis: with Deposit of Diphtheritic Membrane in the Pharynx, Larynx, and Bronchi.—Mr. R. W. PARKER read notes of the case. The patient was a little girl, aged 3, under the care of Mr. Thomas Smith, in the Hospital for Sick Children. She had put her mouth to the spout of a kettle, which was boiling on the hob, and from which steam was actually issuing at the time. She would not swallow anything that same evening; but there was no difficulty with her breathing. Indeed, the immediate effects of the accident seem to have been slight, as she was not seen by a medical man for thirty-six hours. It was not until three days afterwards that the breathing became really affected, and she had a "croupy" cough for the first time. During the next two days, her breathing became more laboured, and her voice weaker; and, on the sixth day from the accident, she was admitted into the hospital. She was now exceedingly low and depressed, breathing very rapidly, and with great difficulty, but she did not struggle for breath. Her voice was entirely suppressed. There was great contraction of the hypochondriac regions with each inspiration. The mouth was carefully examined, and the lips, tongue, palate, and tonsils, were found free from any visible injury. On the posterior wall of the pharynx, a small patch of membrane was seen. An ice-bag was applied to the neck, but, at the end of two hours, there was no amelioration, so tracheotomy was performed. Two long pieces of membrane was got up with the aid of a feather; one of them was tubular, and about the size of a crow-quill. The child was greatly relieved by the operation. The general condition, however, rapidly became worse; she ceased to take notice of anything or anybody, and died thirty-six hours later, of blood-poisoning and exhaustion. The *post mortem* examination showed the lips, tongue, and tonsils, to be normal. Two small erosions existed on the hard palate at its junction with the soft. The anterior surface of the soft palate was normal; its posterior surface was rather swollen and mammillated in appearance, from swelling of the glands of its mucous membrane. There was a small patch of membrane on the base of the uvula, and another just above the left arch of the palate, another piece on the posterior surface of the posterior pillars of the fauces: these pieces were not perfectly separable from the mucous membrane. The epiglottis was covered with membrane, and was thickened and swollen, as were also the aryteno-epiglottic folds. The tracheal mucous membrane was intensely red and injected, and coarsely granular in appearance: this appearance extended as far as the tertiary bronchi. In some of the bronchi, pieces of thin, reddish, well formed membrane were found. In the lungs there were patches of slight superficial collapse; the margins and bases were slightly emphysematous. No pneumonia was present anywhere. No urine was observable during life, but a little found in the bladder after death contained albumen and hedgehog-crystals of urates. It was argued, that the membrane was not directly due to the hot steam, therefore, that it was not a slough: 1. Because those parts with which the steam would first come into contact, were not injured, while parts with which the steam could not come into contact were patched with membrane; and, further, because membrane was found in the tertiary bronchi, where, even if the steam penetrated at all, it must have been so cooled by admixture with the contained air, and by contact with the bronchial secretion, that it could not then have caused the extensive mischief described: 2. Because the dyspnoea did not commence until three days after the accident, and only became urgent on the sixth day. The insidious onset of the more acute symptoms, on the contrary, sug-

gested the diphtheritic nature of the complication, and the *post mortem* evidence favoured this view. Mr. Parker maintained that the fact that false membranes had been found under a variety of circumstances, such as scalds of glottis, foreign bodies in the larynx, and in cut-throat cases, could scarcely be urged as an argument in favour of the non-specific nature of such exudations, any more than that the erysipelas which attacked a hospital patient after operation was non-specific, because the patient, though in exactly the same surroundings, had resisted the contagious influence for five or six weeks previously to his operation. Finally, the identity of croup and diphtheria was inferred from the fact, that the same contagion would produce the two diseases indifferently, and, in illustration, the following cases were read. A little girl was taken into the Children's Hospital with typhoid fever, and when she was in the fourth week of the disease, she had laryngeal diphtheria, and had to be tracheotomised. The disease began with a loud croupy cough, and slight hoarseness, which lasted for several days, but there was no dyspnoea. There was no enlargement or tenderness of the submaxillary glands. There was no albumen in the urine; there was no dysphagia; no marked depression; and there was no membrane about the fauces. After an emetic on the fourth day of the disease, she vomited freely, and, in the effort of vomiting, she brought up some tough white membrane; other pieces were brought up on the two following days. Being much worse, she was tracheotomised. On the ninth day after the operation, the urine became albuminous, and continued so for eight or ten days; she recovered. A few days later, another child in this same ward, who was under Mr. Smith for scrofulous disease of the knee-joints, began to be ill, with symptoms of languor and depression; then her temperature rose to 104.4 degs. Fahr., she was flushed, and felt sick, and could not swallow without discomfort. On closer examination, it was found that there was swelling and tenderness of the glands below and behind the angles of the lower jaw. The uvula was of a deep red colour and swollen. Both tonsils were enlarged, and deep red in colour, and, on the inner surface of each, there was a patch of white membrane of the size of a fourpenny-piece. The voice was pharyngeal in quality, otherwise not altered. There was no dyspnoea; no albumen in the urine. In eight days from the commencement, the membrane had entirely disappeared, the swelling of the throat was subsiding, and the child's general condition improving; she quite recovered. A fortnight later, one of the nurses in the same ward had a sore throat. On examination, the fauces were found red and congested, the tonsils large, and the left one spotted with half-a-dozen small white dots. The submaxillary glands were not enlarged. Now, had the first case not been operated on, she would quickly have died, and the disease in her case would have been found localised in and confined to the larynx, and, on *post mortem* examination, it would have been demonstrated as true croup; while, had the second child died, the case would just as certainly have been called one of diphtheria; and there would be no hesitation in speaking of the third case as follicular tonsillitis. No doubt these three diseases were due to one and the same cause, the difference in manifestation being the result of idiosyncrasies of the individual attacked, or of the organ implicated.

Dr. DICKINSON could not concur in these conclusions. The child must have been peculiarly unfortunate to have suffered from the effects of scald one day and to have been attacked on the next with diphtheria. Irritants, as boiling water, acids, etc., were well known to produce membranous inflammation of the larynx. The assertion that croup and diphtheria were identical, was one of the most startling manifestations of the present change in the current of thought in medicine. It might, indeed, be impossible to discriminate croup and diphtheria by the occurrence of membranous inflammation of the larynx alone; but how could a case of scarlet fever be distinguished after death from one of simple cyncanche pharyngea? or how, as Dr. Moxon had pointed out, could Asiatic be distinguished from English cholera when the anatomical lesion was alone presented? or contagious erysipelas from the same affection following a gumboil or inflamed tooth? Clinically, however, typical cases of croup and diphtheria differed most widely. Croup began with nasal or bronchial catarrh, and the inflammation, spreading to the larynx, led to the formation of membrane. Diphtheria had no antecedent catarrh, but was ushered in by a general febrile condition resulting from a specific poison, and was accompanied by the formation of false membrane primarily on the pharynx, which might spread to the larynx. In the worst cases, the exudation was limited to the pharynx, nasal passages, and mouth, and death occurred from asthenia. The laryngeal inflammation in croup had no tendency to spread. Glandular enlargements, the early appearance of albumen in the urine, and the frequent supervention of peculiar nervous sequelae, characterised diphtheria. The etiology was different: croup was frequently traced to cold, diphtheria mostly to exposure to some definite

poison, e.g., sewer-gas. The outbreak of diphtheria in the Children's Hospital, quoted by Mr. Parker, was traced to defective drainage and escape of sewer-air into the ward. The subject was one peculiarly appropriate to the Society, whose President (Sir W. Jenner) had recently declared in favour of the identity between the two affections, while he (Dr. Dickinson), on the other hand, thought the arguments in favour of their non-identity to be unanswerable, although cases were occasionally met with which it was difficult to place under either category.—Dr. HILTON FAGGE fully concurred in the views expressed by Dr. Dickinson, and he was partly influenced by the fact, that membranes might be found in the larynx under very different circumstances, as in cut-throat. Every few weeks or so, a child was brought to a London hospital suffering from croup. If it died, a membrane might or might not be found in the larynx, and it might reach the bronchi. In the pharynx, there was usually more or less membrane. In old times, the presence of membrane on the pharynx in croup was seldom recognised; but, since the introduction from the French of the term "diphtheria", it had been taught that any membrane whatever seated above the aryteno-epiglottic folds was diphtheritic. Moreover, the older physicians, recognising croup from its clinical features, might readily have passed over small patches of exudation on the palate and fauces. Only a small proportion of cases met with in an epidemic of diphtheria presented a marked laryngeal character; and, according to his experience, it was the rarest thing to find diphtheria admitted into a hospital apart from an epidemic. It was, indeed, highly probable that so-called "laryngeal diphtheria" in children was merely croup. He believed that every true case of diphtheria was as contagious as the exanthemata. The last case he had seen was nine years ago, when a patient with chorea, admitted into the same bed occupied just before by a case of diphtheria which was fatal, contracted the disease and died, although all precautions had been taken. It was far better always to act on the belief that diphtheria was very contagious. Croup and diphtheria could not be distinguished by their anatomical characters; but he would say that, in London, a case of membranous laryngitis would probably be croup. Much of the confusion between the two affections arose from the use of the word "diphtheria" by German writers; thus Virchow gave the term "diphtheritic" to that form of inflammation in which the deeper layers of the mucous membrane were infiltrated, the whole altered membrane sloughing off; and Niemeyer, adopting this view, applied it to epidemic diphtheria. This was clearly erroneous, and a more correct interpretation was given by Rindfleisch, who admitted the anatomical identity between laryngeal and pharyngeal croup (diphtheria). But it had led to the view being taken in England that the diphtheritic membranes should be inseparably adherent, and should invariably leave a raw surface when detached.—Dr. DUCKWORTH also concurred with the two preceding speakers, and pointed out that, although the presence of membrane on the pharynx could not be held to be distinctive of diphtheria, there was invariably in this disease a peculiar turgidity and redness of the mucous membrane of the pharynx (even in purely laryngeal cases) which was never seen in croup.—Mr. T. SMITH pointed out that Mr. Parker's case refuted the statement that the membrane resulting from local irritation was not the same as that resulting from diphtheria; for here it had no character of a slough, but was precisely the same as a diphtheritic exudation.—Dr. YEO had recently been converted to the view, that croup and diphtheria were identical; for he had seen cases presenting the symptoms of croup to which diphtheritic symptoms were added. One such, a child, died from blood-poisoning, although tracheotomy had been performed and had afforded great relief. Here the larynx and trachea were studded with circular patches of exudation. He thought Mr. Parker was quite justified in his opinion that the scalding water did not pass the glottis; and one explanation of the escape of the buccal mucous membrane might be found in the fact, that this was ordinarily exposed to rough substances without injury.—Mr. BARWELL had seen several cases of scald of the throat produced by children sucking the spouts of tea-kettles. The child, being frightened, made a deep inspiration, and thus drew water into the back of the throat, so that it was quite conceivable that some might enter the larynx. Only one case had been seen after death, and in that the trachea was lined by false membrane, while the tongue was abraded from contact with the spout of the kettle. He agreed with Dr. Dickinson that it would be very remarkable had a child been attacked with diphtheria directly after it had scalded its throat. Dr. CAVLEY pointed out that the theory of non-identity required that more than one cause could produce the same effect; in the opposite view, many effects had the same cause; one of the chief arguments against the identity of croup and diphtheria being, that the identity of the membrane was no evidence of the identity of the disease. But it was notorious that the same poison or the same irritant produced very different effects in different

individuals, the differences shading one into another. It was certainly not his experience that, as Dr. Fagge had stated, cases of croup admitted into London hospitals were equally distributed throughout the year. He had had cases at the North-Eastern Hospital for Children, which, from their sudden onset and rapid course, would be called croup, proving fatal within forty-eight hours, whether tracheotomy were performed or not. In all, false membrane had occurred in the fauces. Such cases were truly laryngeal diphtheria, so rapidly fatal as not to show any other of the symptoms of that disease. There were two distinct forms of diphtheria: one in which the general manifestations predominated, and the other in which the local symptoms were chiefly exhibited; cases of the latter kind occurred even in epidemics. He believed, then, the two diseases to be identical, and both due to the same poison.—Dr. GREENHOW thought that Mr. Parker's case was one of diphtheria, in which the scald played the part of a determining cause; and he strongly upheld the view, that croup and diphtheria were perfectly distinct affections. The marked depression characteristic of diphtheria was absent in croup. He had recently had under his care a case of croup, which was treated by leeching and depressing remedies, emetics, etc., with success; but such treatment could never be adopted in diphtheria. A few weeks ago, a child was admitted under his care, in which the diagnosis was at first doubtful; but tracheotomy was performed without relief, and the enlargement of the glands behind the jaw pointed in favour of diphtheria. After death, some small patches of exudation were found on the fauces, beyond the reach of observation during life. Four days afterwards, the sister of this patient was admitted with diphtheria, and died; while the nurse in charge of the two cases was attacked, and was only now convalescent. The nature of the membrane was of minor importance, for it differed widely in different cases of diphtheria. He had only been enabled to examine after death one case of croup, in which death resulted from absolute choking by the false membrane; here a tube of membrane was found confined to the larynx and trachea, the surface beneath being injected, but in other parts pallid and free from the vascularity correctly described by Dr. Duckworth as occurring in diphtheria.—Mr. PARKER, in reply, pointed out that those parts nearest to the steam were least affected; and he could not accept Mr. Barwell's explanation of the formation of the membrane in the trachea from direct irritation. The case of laryngeal diphtheria following typhoid, which he had related, was acknowledged by all at the time to be diphtheria, although confined to the larynx, and the membrane being exceedingly tough and white. The early symptoms in this case were those of croup, *i.e.*, of catarrhal character; but he had seen cases of croup in which there was but little primary coryza. Diphtheria might occur without deposition of membrane, with merely coryza and reddened fauces. Passing to the sequelæ, he said that evidence was wanting that paralysis was a necessary sequela of diphtheria; and it would hardly do to base the diagnosis of a disease upon its sequelæ, as had sometimes been done in diphtheria. In that view, dropsy or perforation of intestine might be held to be distinctive of scarlatina or typhoid fever, and yet it was very likely that these sequelæ could be prevented by timely treatment. Thus no case of scarlet fever treated from its commencement in the Children's Hospital had led to dropsy; while those cases in which dropsy supervened were precisely those in which little or no treatment had been adopted; so also with typhoid fever. With regard to albuminuria, in one of the two undoubted cases of diphtheria he had mentioned, there was much albumen; in the other, none. Was croup non-contagious? The last case in the Children's Hospital for which tracheotomy had been performed with success produced violent inflammation in the eye of the nurse in charge, by some of the membrane being expectorated into the eye. Nor was the amount of depression any diagnostic feature; and he repeated that he had never seen a case of asthenic croup in an impoverished child; the type, then, varied with the individual. There was no glandular swelling in the case of diphtheria following typhoid which he had related.

HARVEIAN SOCIETY.

THURSDAY, APRIL 5TH, 1875.

W. H. BROADBENT, M.D., President, in the Chair.

Facial Neuralgia.—Mr. HENRY SEWILL related three cases of facial neuralgia, which, after resisting treatment for considerable periods of time, were cured by the extraction of carious teeth with inflamed nerves. The patients had not suffered from toothache.—Dr. BROADBENT remarked, that in his experience several cases of the most severe facial neuralgia, in which diseased teeth were not suspected by the patient, had been permanently relieved by dental treatment.

Tinnitus Aurium.—Mr. GEORGE FIELD read a paper on this sub-

ject. He first gave its various causes, and the treatment that had been recommended, etc. He then related fifteen successful cases of severe noises in the ear, treated by him by galvanism at St. Mary's Hospital, all of which had failed to get relief from other modes of treatment. He used Dr. Stohrer's double-celled induction apparatus, applying the galvanism directly to the membrana tympani by means of a probe passed through an ear speculum, made for the purpose by Messrs. Krohne and Sesemann. A piece of platinum wire was fixed to the speculum, and by this the current was carried to the tympanic membrane. Most of these patients had great concavity of the membrana tympani, with more or less deafness and obstruction of the Eustachian tubes. Some of them had suffered from noises in the ears for many years, and the sounds described by them were various. The "tinnitus" in some cases was almost unbearable before this mode of treatment was adopted. Mr. Field maintained, that galvanism no doubt stimulates the intrinsic muscles of the ear, and therefore enables them to perform their proper function. He said he had reason to believe that the stapes often remains fixed within the foramen ovale in these cases of singing in the ears. Such a condition doubtless does, from the continued contact of the stapes with the internal ear, induce a constant formation of false sounds. The partial withdrawal of the stapes, effected by contraction of the stapedius muscle, would be followed by a reduction in, or a temporary removal of, such false sound. And he would, therefore, suggest, that if this stimulation be carried on perseveringly, the muscles may regain their tone and exert their proper influence in the auditory function. A discussion followed, in which the President, Mr. Edmund Owen, Mr. Thomas, Mr. Browne, Mr. Sewill, and Dr. Farquharson took part.

ASSOCIATION INTELLIGENCE.

MIDLAND BRANCH.

A QUARTERLY meeting will be held at Lincoln on Wednesday, May 5th. Members desirous of reading papers are requested to communicate at once with

C. HARRISON, M.D., *Hon. Sec.*

Lincoln, April 11th, 1875.

BORDER COUNTIES BRANCH.

THE spring meeting of the Branch will be held at Carlisle on May 12th, 1875. President, Dr. Green, Kendal; President-elect, Dr. W. A. F. Browne, Dumfries. Gentlemen intending to read papers, or be present at the dinner, are requested to give notice to the Secretaries.

HENRY BARNES, M.D. } *Hon.*

Carlisle, April 13th, 1875.

J. SMITH, M.D. } *Sec.*

MIDLAND BRANCH.

A QUARTERLY MEETING will be held in the Board Room of the County Hospital at Lincoln, on Wednesday, May 5th, at two P.M.

Notice has been received of the following communications:

Ether as an Anæsthetic, and Notes of Cases. By C. Bell Taylor, M.D.

A case of Scald of Glottis, with recovery after the operation of tracheotomy. By the President.

A meeting of the Council of the Branch will be held at 12.30 on the same day, at the house of the President in James Street.

Lincoln, April 19th, 1875.

C. HARRISON, M.D., *Hon. Sec.*

BATH AND BRISTOL BRANCH.

THE sixth ordinary meeting of this Branch will be held at the York House, Bath, on Thursday evening, May 13th, at 7.15 P.M. F. Mason, Esq., President.

R. S. FOWLER } *Hon.*

Bath, April 1875.

E. C. BOARD } *Sec.*

METROPOLITAN COUNTIES BRANCH: ORDINARY MEETING.

AN ordinary meeting of this Branch was held at 11, Chandos Street, on February 19th; T. B. CURLING, Esq., President, in the Chair.

Cerebro-spinal Paresis with Intense Neuralgia.—The history of a case of this kind, by Dr. LOCKHART CLARKE, was read in his absence by Dr. FARQUHARSON, one of the Honorary Secretaries. A discussion followed, in which Dr. Fothergill, Dr. W. Dickson, Mrs. Garrett-Anderson, Mr. Sedgwick, the President, Dr. Farquharson, Dr. Dowse, and Mr. Allingham, took part.

CORRESPONDENCE.

PUERPERAL FEVER.

SIR,—In response to your invitation to members to give publicity to their views on puerperal fever, I send you the result of my experience, extending over a period of fifteen years.

In the beginning of my career, I acted as *locum tenens* for a gentleman who was obliged to leave home owing to the prevalence of puerperal fever in his practice. He had, in a few weeks, attended many cases of this nature, some of them proving fatal, and he left under my care several patients in various stages of the disease. One only died, the rest (daily, and often twice daily, visited by myself) recovered. I may here state that the fever was not generally prevalent, but was restricted to the practice of which I was in charge. During the few weeks I officiated, I delivered from twenty to thirty women, yet of all these not one was attacked by the disease.

Now the question which seems to me to upset the ordinary belief as to the communicability of contagion by the hand or clothes of the accoucheur is, how did it happen that, as I was in such close contact with patients suffering from a disease generally acknowledged to be very contagious, there was absolute immunity in the cases I delivered? I have in my time attended many isolated cases of puerperal fever, why did the disease not spread to the other cases I delivered during such attendance, if the clothes readily communicated it? A neighbour of a patient suffering severely from puerperal fever, and who administered vaginal injection, and generally acted as nurse, acted at the same time in the same capacity for another woman; no bad result ensued.

Three months ago this disease appeared in my practice. During a fortnight, out of nine cases I attended, eight were attacked, two ending fatally. I ceased practice, spent in the interval a fortnight at a hydropathic establishment, took various baths and out-door exercise, and, not feeling well, put myself under an alternative course of treatment. I resumed the practice of midwifery after five weeks cessation. All the cases subsequently delivered have done well. Neither scarlatina nor any other fever was prevalent in our district, and no other medical man, save myself, had any case of the kind.

From consideration of facts such as these, I have formed the opinion, first, that there is a form of puerperal fever communicated by the accoucheur; second, that it is extremely improbable that it is communicated by effluvia from the clothes or any merely external source. Cases such as I have cited confirm me in the belief that we must look for some other explanation, and that furnished by one of your correspondents a few weeks ago, seems to me to be the one most reasonable and worthy to be entertained, viz., that the poison originates, or has its *habitat* in, and is exhaled from the person of the accoucheur. —Yours truly,

GERM.

THE CONTAGIOUS DISEASES ACTS.

SIR,—When such persistent efforts are being made by certain parties to obtain the repeal of the "Contagious Diseases Acts," I think it would be well if medical men who have been, or are, called upon to treat venereal diseases, would give their opinions and the foundations for such opinions—*Whether the "Acts" in question should be repealed or not.*

I have been the medical officer to the Tenby district of the Pembroke Union for many years. In the vicinity, we have, upon an average, from 130 to 140 soldiers, at the Huts and Fort, who are drafted from the Depot at Pembroke Dock to this locality for rifle drill and practice; and, after a few weeks, exchange for other detachments coming up for the like purpose. We are not under the Acts; but the fact admits of no dispute, that, up to the passing of the Contagious Diseases Acts, venereal disease was prevalent in this locality, and my list of patients was never free from such cases. Since the Acts have been in force and the troops protected, venereal diseases have steadily diminished in frequency, until such complaints are all but extinct in this locality. I have not seen a single case of venereal disease of any kind for two years and upwards; and I have the permission of my friend Surgeon-Major Venour (the medical officer in charge of the troops) to state that his experience coincides with my own.

It is not my intention to enter upon a discussion of the subject, under the pretext that the "Acts" have an immoral tendency, or the reverse. It is notorious the parties brought under surveillance are well known to have little, if any, morals to part with; and I must have been very much mistaken if thirty or forty years ago the inhabitants of our large cities, or the soldiers located in barracks thereat, were more moral than at the present time, because venereal disease was prevalent, or the fear thereof. That venereal disease will ever be eradicated from our large cities I do not expect, but that the ravages of these distressing complaints may be in part in course of mitigation, I have no doubt. It

does seem absurd, in my humble opinion, that a soldier or civilian is more moral because he has had, or expects to have, venereal disease. That such is the inference certain parties would suggest is obvious, fortunately without effect. Neither the actual contamination or the fear of infection has prevented the spread of such complaints, and never will. Therefore, by all means let the "Contagious Diseases Acts" be carried out to their legitimate issue, without let or hindrance. Such is the opinion and conclusion of yours obediently,

GEORGE CHATER.

Tenby, April 16th, 1875.

SIR,—I am obliged to Dr. Parkes for affording me the opportunity of correcting an unintentional injustice to various gentlemen who have taken part in the recent controversy. He says, in his letter in to-day's JOURNAL, "there is one sentence in Dr. Nevins's letter which requires a word of reply." He says he has called upon the advocates of the Acts to refer to Dr. Balfour's returns, "instead of their own picked and unauthentic statistics"; and Dr. Parkes goes on to add, "The figures furnished by the various medical officers are perfectly 'authentic'." They are taken from the regimental returns, which are transmitted to head-quarters, and form the basis of the tables there calculated. Dr. Nevins has no more right to doubt the accuracy of the figures given by Surgeons-Major Fox, Gore, Efolliott, and others, than he would have to doubt the figures of any hospital physician of London or Liverpool who laid the statistics of a disease before the profession. I have thought it necessary to assert the good faith and accuracy of the Army Medical Officers against Dr. Nevins's unfounded assertion, that their figures are 'unauthentic'."

In the beginning of my letter, from which Dr. Parkes has quoted, I objected to the use of "unpublished and unauthenticated statistics", and was not aware, until he pointed it out, that in a later paragraph of the same letter I had written "picked and unauthentic statistics". I have not the slightest thought of imputing want of good faith to any of my opponents in this controversy, nor do I believe that it has ever been implied in any of my letters; and if the accidental use of the word "unauthentic" has been so understood, I trust they will accept this *amende*. What I have throughout objected to has been the use of statistics "unauthenticated" by publication in the Army Returns, and therefore not accessible to the profession at large, and affording no means for the correction of accidental inaccuracies. I regret that, whilst zealous about an accidental and doubtful imputation upon the good faith and accuracy of his friends, Dr. Parkes should have allowed himself to write about his opponents, "the tactics of the opponents of the acts are so shifty, etc." The controversy, hitherto, has been very free from personal imputations, and I trust it will so continue to be carried on, that it may leave behind it no remembrance of words which their writers would wish to be forgotten.—I am, sir, yours faithfully,

J. BIRKBECK NEVINS, M.D.

THE DEBATE AT THE PATHOLOGICAL SOCIETY.

SIR,—When speaking at the last meeting of the Pathological Society, I had intended, had I not been stopped by the clock, and by the evident feeling of the Society that the debate should be adjourned, to ask Dr. Bastian to give us in his reply some explanation of the many published experiments which seem, to those who hold to the germ-theory, to be distinctive of the views held by him. I refer more especially to the "porous cell" experiments of Klebs, the diffusion experiments of Chauveau, both repeated by Sanderson; the experiments recently published by Roberts of Manchester, in the *Philosophical Transactions*, and those of Lister in the *Quarterly Journal of Microscopical Science*, and the *Lancet* of April 3rd. I think the facts they place before us are so important that any paper or discussion which does not deal fully with them, cannot be said to be anything but one-sided; and I trust Dr. Bastian will, at the next meeting, let us have his explanation of them.—I remain, yours, etc.,

J. KNOWSLEY THORNTON.

Park Street, Grovesnor Square, April 27th.

TESTIMONIAL.—The committee of the Surrey Reformatory School for Girls has presented a valuable microscope to their honorary physician, Dr. G. P. Rugg, on his retirement from that office, with a suitable inscription, in "testimony of their appreciation of the valuable and efficient services rendered by him as honorary physician to the school during a period of eight years."

PRESENTATION.—On April 26th, an address, handsomely illuminated, was presented to Dr. O'Keefe, of Queen's College, Cork, by the students attending the classes in *Materia Medica* and *Medical Jurisprudence*, in which they expressed their appreciation of the value of the lectures delivered on these subjects, and of the great attention they received from that gentleman.

PUBLIC HEALTH AND POOR-LAW MEDICAL SERVICES.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

SANITARY MATTERS AT LEWES.—The medical officer of health reports that the recent outbreak of typhoid fever in Lewes has rapidly died out, and that no fresh case had been reported during the fortnight embraced by this last return. During the last three quarters, the deaths in Lewes referred to fever have been nine, twenty-five, and fifteen, respectively. The usual quarterly meeting of the Town Commissioners was held on the 7th inst., when several matters connected with the sanitary condition of the town were discussed. It was stated that, under the present contract system, the scavenging and watering of the town were inefficiently performed; and it was, therefore, proposed that the commissioners should take this work into their own hands. At the present time, the ashpits, it was said, were emptied very irregularly, and at times it was difficult to get them emptied at all. The chairman, in pressing the proposition (which met with some opposition, on the ground that the new system would probably be more expensive than the old), very properly urged the importance of all refuse being regularly cleared at least once a week, especially from small houses. Most of the commissioners agreed that the existing arrangements for the clearance of ashpits and refuse were a disgrace to the town, and that they could only be put upon a satisfactory basis by taking the matter into their own hands, which was desirable, even should it result in a slight increase of expense. These views prevailed, and the proposition was ultimately carried with but one dissentient voice. Efficient scavenging forms an important part of the sanitary organisation of a town.

SWANSEA.—At the monthly meeting of the Swansea Rural Sanitary Authority, the medical officer of health, Mr. Rogers, reported that, during February, the death-rate had exceeded 28 per 1000; this large mortality being principally due to scarlet fever and to bronchial affections amongst children, resulting mainly from the keen easterly winds and the great alternations of temperature which had been experienced. The type of the prevalent scarlatina is stated to be very malignant, and this may perhaps in part be explained by the fact that, in many instances, the population live in badly constructed houses, which are ill-drained, and have neither proper water-supply nor efficient means of scavenging. Disinfection appears to be carried out in the district; but, except this step be seconded by isolation, which under existing circumstances is stated to be impracticable, it cannot be expected to result in much good.

WILLENHALL.—In the Willenhall urban district, the mortality during the past year has been 23.4 per 1000, and, according to Mr. J. T. Hartill's report, enteric fever has been very prevalent. The report only contains a brief *résumé* of the sanitary work which has been carried out, and it does not enter into details as to the probable causes of the mortality. The supply of water is, however, stated to be intermittent, and it is believed that risk of local contamination is thus favoured.

SHORT HEATH.—Mr. Hartill reports that the sanitary condition of this district is likely to be much improved when the water-supply now being provided by the Wolverhampton Waterworks Company has been carried throughout the locality. In many other respects, however, sanitary improvement is evidently much needed. There is no efficient sanitary inspection, the removal of night-soil is not properly effected, and in some parts there is overcrowding, and persons resident in ill-ventilated cottages are subjected to the effluvia emanating from foul ditches.

CAMPBELTOWN.—At Campbeltown, in Argyllshire, considerable improvement is stated to have been effected in the sanitary condition of the borough; but the evils resulting from overcrowding are still great, many families being huddled together in ill-ventilated tenements. This condition is stated to be increasing every year with the increase in population, and it is found to be one of the greatest obstacles to sanitary reform. Dr. Gibson, in his report, instances cases where, in two small ill-ventilated apartments, as many as seventeen persons were found residing; and he points out that, under such conditions, it would be quite impossible for him to stay the spread of any infectious disease which had once obtained a hold in these haunts. Fortunately, such diseases are at present rare in the district, and the spread both of typhus and of small-pox has in several cases been prevented by the

immediate removal of the first cases to hospital. The provision of more closet-accommodation is also an urgent want in the borough, for at present every quiet street and lane are made the depositories of human filth. In many of the inferior houses, there are no closets at all, and, as there is a great dearth of public closets, it is at present impossible to put an end to this nuisance. After hearing Dr. Gibson's report, the Council resolved to give both him and the inspector of nuisances an increase of salary, and it is to be hoped that the adoption of this step indicates a determination on their part to deal energetically with the gross sanitary conditions reported to them as still prevailing in their district.

THE HEALTH OF DUDLEY.—The usual quarterly meeting of the Dudley Town Council was held on April 6th, at which was read the report of the Special Committee which had been appointed to consider Dr. Ballard's report upon the sanitary condition of the borough. The recommendations of the Committee were, principally, that a full statement of what had been done by the Council to remedy the evils pointed out by Dr. Ballard should be forwarded to the Local Government Board. This included efforts to obtain a better and a more regular water-supply; the covering in of foul ditches; the suppression of filthy undrained pigsties; the better regulation of slaughter-houses; the gratuitous distribution of disinfectants; the provision of a complaint-book for the use of the inhabitants; the pulling down of houses unfit for human habitation; the appointment of additional inspectors of nuisances; and an increase of the salary of the medical officer of health. The report also stated that a public mortuary and a hospital for infectious diseases would both be built shortly. The Mayor expressed his willingness to take all the blame upon himself if the Town Council and the Sanitary Committee were not kept to their work; and it would really seem as if a reign of real sanitary activity were now to prevail in this unhealthy town. That it is much needed, is proved by the last report of the health-officer, from which it appears that the death-rate of the borough is still equal to 39.2 per 1,000. The deaths included twelve from whooping-cough, and three from puerperal fever, which is now very generally prevalent. There had been four cases of small-pox in the town; but, by prompt isolation, the spread of the disease had been prevented, and it was reported that all the patients were convalescent.

SELBY.—An interesting report has been issued by Dr. Parsons on the sanitary condition of the Selby rural district during the past year. The district is situated in the centre of a wide alluvial plain, through which runs the Ouse; it is also skirted by the Rivers Aire, Derwent, and Wharfe. The surface is generally flat, and but few houses are more than thirty-five feet above the sea-level. Taking the average of the past six years, the general mortality for the district has been 18.0 per 1000; but it has varied in different groups of villages from about 22 to 15. This difference is attributed to the closer aggregation of dwellings, to the consequent concentration of the refuse matters of the population, and to the greater want of a free circulation of air in the villages of the former class. One of these evils is, however, in course of removal, the ordinary midden-privies being replaced by box-closets. The boxes are made to fit accurately beneath the closet-seat, and the latter lifts on hinges, so that the ashes may easily be thrown day by day upon the excreta. The boxes are further fitted on wheels, so that, when full, they can easily be wheeled away to a spot where their contents may suitably be deposited. Much of the water with which the district is provided is procured from wells often sunk in an alluvial or peaty soil, and more often still fouled by the percolation into them of filth from drains, privies, and farm-yards. Indeed, the supply derived from the rivers is found to be superior to that procured from many wells, and even that derived from the Aire is stated, after the sediment has subsided, to contain less albuminoid organic matter and chlorine than that of most of the wells. Great difficulty is, however, experienced in dealing with the question of water-supply; for, although power is given under the Sanitary Law Amendment Act, 1874, to close polluted wells, there is no power to compel the owners of property to provide a proper supply of water by sinking a new well. Dr. Parsons has been in communication with the Local Government Board on this point, and he has been informed that the obligation on the part of an owner of property to give his houses a proper water-supply, provided this can be done "at a rate not exceeding twopence per week", does not apply to cases where such a supply can only be obtained by digging a well. This is a point of extreme importance, and, if the view adopted by the Local Government Board be correct, it is evident that some modification of the existing law on this point is required. Dr. Parsons suggests that, in any future legislation, the words "at a rate not exceeding twopence per week" should be altered into "at a reasonable cost". The report concludes with a detailed account of the special

sanitary work required in each portion of the district, and contains some excellent advice as to the necessity for using disinfectants with lavish liberality wherever they are required. Parsimony, especially in this matter, is mistaken economy, and it is calculated to do the more harm, because of the false sense of security it tends to give.

HARDINGSTONE.—At a recent special meeting of the Hardingstone rural sanitary authority, Mr. Haviland, in an elaborate paper, drew attention to the main causes of disease in this district, and pointed out the extreme fatality of typhoid fever and of phthisis. As regards the former disease, Northamptonshire, in which this district is situated, affords a specimen of the high mortality resulting from it. Consisting of twelve registration districts, it only contains one, namely Oundle, in which the mortality from "fever" during the decennial period 1851-60, was below the average, while five districts, including Hardingstone, had a fever mortality considerably in excess of the average. This mortality has since that date been maintained, and, in Mr. Haviland's opinion, it is, to a great extent, due to peculiarities of soil which tend to favour the spread of this disease, mainly by water pollution. Thus the district lies mainly upon the great oolite, a porous limestone, and upon the porous Northampton sands with its ironstone, and the water which descends through these two strata are held up in them by a bed of impervious and tenacious upper lias clay. Such geological sites are clearly conducive to the spread of typhoid fever, if the soil be once fouled by filth, for they naturally give easy passage to the rainfall to form springs, but they, at the same time, also admit the soakage of filth which is derived from cesspools, badly constructed drains, and dungheaps, and the whole is upheld by an underlying impervious bed. In order to obviate the evils attendant upon such peculiarities of site, Mr. Haviland stated that the abolition of the cesspool system was essential, and in its place he advocated the organisation of a system of frequent scavenging and the establishment of dry-closets. Unless these steps were carried out, he confidently assured the authority that the high mortality of past years would most certainly become permanent. Hardingstone is almost exclusively a rural district, but its mortality in the ten years 1861-70 was as high as 20 per 1,000 living, and the fever mortality during the same period was in excess of that prevailing in Northampton. In the course of his paper, Mr. Haviland referred to some outbreaks of diphtheria, and he stated that he was then making inquiry as to the connection of this disease with overcrowded churchyards amongst other causes. There is hardly any disease concerning the causation of which more precise investigation is required, and it is from rural districts, where isolated outbreaks occur, that a clearer knowledge of its means of spread must in all probability come.

POOR-LAW MEDICAL APPOINTMENTS.

BANNISTER, William, M.R.C.S.Eng., appointed Medical Officer and Public Vaccinator for No. 1 District of the Havant Union, *vice* W. Steadman, M.R.C.S.Eng., resigned.
LAVIS, Michael D., L.R.C.P.Ed., appointed Medical Officer and Public Vaccinator for the Bushey District of the Watford Union, *vice* W. E. Barton, L.R.C.S.I.
PAGE, Edward S., L.F.P.S.Glasg., appointed Medical Officer and Public Vaccinator for the Solihull District of the Solihull Union, *vice* T. Lowe, M.R.C.S.Eng., resigned.
PAUL, Ernest W., M.R.C.S.Eng., appointed Medical Officer and Public Vaccinator for the Calne Union, Wilts, *vice* H. W. A. Sandell, L.R.C.P.Ed., resigned.
PRENT, Evan, M.D., appointed Medical Officer for the Llanharadril District of the Ruthin Union, *vice* E. P. Williams, M.D., whose appointment has expired.
SHANNON, Thomas E., M.D., appointed Medical Officer and Public Vaccinator for the Longford District of the Ashbourne Union, *vice* T. G. Copestake, M.R.C.S.Eng., resigned.
WILLIAMS, Robert, M.B., appointed Medical Officer for No. 2 District of the Leominster Union.

MILITARY AND NAVAL MEDICAL SERVICES.

INSPECTOR-GENERAL HENRY S. DONNETT, M.D., C.B., has been appointed to Plymouth Hospital, *vice* Minter, retired.

DR. DONNETT, Deputy Inspector-General of Hospitals and Fleets, doing duty at Malta Hospital, has been promoted to the rank of Inspector-General, *vice* Minter, placed on the retired list.

FLIEB-SURGEON J. G. T. FORBES, who, owing to a close application to his work in the Medical Statistical Department at the Admiralty, was lately struck down by paralysis, is slowly improving in health, but it is believed that he will never be able to resume the discharge of his highly useful and onerous duties.

PROMOTIONS AND RETIREMENTS IN ARMY MEDICAL DEPARTMENT.—Surgeon A. C. Gaye to be Surgeon-Major, *vice* A. C. Ross,

M.D., retired upon temporary half-pay.—Surgeon W. E. Alston, M.D., to be Surgeon-Major, *vice* J. Jardine, M.D., retired upon temporary half-pay.—J. A. Scott to be Surgeon-Major, *vice* W. Lapsley, retired upon half-pay.—Staff-Surgeon J. J. Henry, from half-pay to be Surgeon-Major, *vice* G. McG. Carolan, retired upon temporary half-pay.—Surgeon-Major T. Teevan retires upon temporary half-pay.—Surgeon-Major P. H. E. Cross retires upon half-pay.—Surgeon S. W. Handy, upon half-pay, resigns his commission.

MOVEMENTS OF ARMY MEDICAL OFFICERS.—Surgeon-Major F. Odevaire, in medical charge 84th N.I., is allowed furlough to Bombay for one month from date of quitting regiment, preparatory to furlough to Europe on private affairs.—Surgeon-Major W. D. T. Ticehurst, in medical charge 13th Regt. N.I., is allowed furlough to Europe for two years, from date of departure in April.—Surgeon F. Johnson has arrived in Dublin, from Dunmore, and been ordered to do duty at the Station Hospital, Phoenix Park.—Deputy Surgeon-General Grant, M.D., has been struck off the strength of the Curragh District on embarking for Bermuda, to assume the duties of principal medical officer at that station, and will be succeeded by Deputy Surgeon-General Vere Webb.

RECENT PROMOTIONS IN THE NAVY.

THE Army and Navy Gazette, in reporting that Dr. James J. L. Donnet, Deputy Inspector-General of Hospitals and Fleets (1867) has been promoted to the rank of Inspector-General, *vice* J. M. Minter, placed, owing to age, on the retired list, points out that, in promoting Dr. Donnet, the Lords of the Admiralty have passed over, in consequence of a most unfortunate technical objection, two most deserving and very valuable public officers—Deputy-Inspector Mackay and Deputy-Inspector Macleod, both of whom are several years senior to Dr. Donnet. We sympathise with regret that there is a difficulty in recognising the services of the two able officers named; at the same time it is right to point out that there is no question here of a merely technical objection, but the direct and express provision of an Order in Council. By the Order in Council of the 7th August, 1869, it is provided that no Deputy Inspector-General of Hospitals and Fleets shall be promoted to the rank of Inspector-General of Hospitals and Fleets, unless he shall have served five years as a Deputy Inspector-General, during three years of which he shall have been in charge of a foreign hospital, or of a fleet or squadron. Deputy-Inspectors Mackay and Macleod, who have respectively nine and seven and a half years' standing in that rank, have been on continuous full pay in England. In giving way in promotion to younger officers who serve in all climates, and are on full pay alternately, they fulfil the express terms of the order. The principle is, we believe, considered in the service to be sound, and one which ought not to be invalidated. At the same time, it ought not to be applied retrospectively to officers on active service when it was brought into law; and these officers might have been promoted in due turn *in italics* out of the limited list of available posts. This might, we suggest, fairly be the subject of a special Order in Council for their promotion.

ARMY MEDICAL SERVICE.

SOME very pointed remarks on the Army Medical Service have been put in a very terse way, in a small printed sheet of six pages, by "X". The writer shows that the mere guarantee of promotion of surgeons at fifteen years, which the Secretary of State for War, in bringing forward the Army Estimates, stated he believed he saw his way to granting, will not bring back the value of an army medical commission to what it was under the warrant of 1858. This was the warrant which Dr. Alexander, who was then Director-General of the Army Medical Department, succeeded in obtaining after a prolonged struggle, and which has since been much tampered with. In addition to certain promotion to the step of surgeon-major at the end of fifteen years, there must be a more steady flow of promotion. We agree with "X" in thinking that one of the most powerful safeguards against stagnation and wholesome spurs to exertion was taken away when Clause 7 of the warrant of 1858 was expunged. By this clause, it was ordered that all promotions to the inspectorial ranks should be given "by selection for ability and merit"; the grounds for the selection being stated in writing, and recorded in the office of the Commander-in-Chief. Instead of selection, seniority has been made the rule; so that, as "X" puts the case, "the sole qualification needed for eminence in the Army Medical Department is good physical health"; while the "feeling amongst the juniors, which should have culminated in respect for the scientific attainments of the seniors of their department, has merged into veneration."

tion for their years". We are sure that there is much truth in this. When men know that it makes no difference in their prospects or advantages whether they distinguish themselves in their profession or not, they are not likely, excepting in isolated instances, to exhibit particular zeal, or to distress themselves by overwork. They are more likely to "take the world easy", and make the preservation of health the first consideration. A remark, attributed to the late Sir John Hall, was quoted in a recent pamphlet on the organisation of the Army Medical Department. It was to this effect. On being asked whether he thought promotion by seniority or selection best, Sir J. Hall replied, "If promotion goes by seniority, God help the department; if by selection, God help the man who has to make it". This sounds very much as if the only interests to be consulted were those of the department, or of the officer on whom the duty would devolve of selecting for the higher grades in it. But we cannot help noticing that there are other interests at stake as well as those of the character and reputation of the department, though these are not to be lightly considered. The interests of patients and of the army at large are not to be neglected. No doubt it is an easy matter for the responsible authorities when seniority is the rule; there is no trouble in making an appointment when all that is to be done is to see what name stands first in the list. This was not the proceeding, however, that was adopted by the governing authorities when they had to appoint an administrative officer for conducting the comparatively recent expedition on the West Coast of Africa. They did not take the oldest general officer on the list because it was the easiest thing to do, but selected an officer who had the necessary professional knowledge, ability, and energy for carrying out the objects of the expedition to a successful issue. Neither did Sir Garnet Wolseley take the members of his staff on a seniority principle, but he selected them from the most competent officers at Woolwich, Sandhurst, or wherever else he could find them. Surely the respective merits of the medical officers must be pretty well known in the office of the Director-General of the Army Medical Department in London; if not, we can only say they ought to be known. If the heads of the medical service are themselves competent professionally, and able in their administrative capacities, they can have no more difficulty in estimating the relative merits and abilities of the medical officers under them than occurs in other branches of the public service. At any rate, if the system of seniority promotion is to continue, we agree with "X" in thinking that the deadlock in promotion will continue also. We commend the remarks of "X" on this point to the notice of the Right Hon. the Secretary of State for War.

SIR,—In discussing the various views regarding the Army Medical Department, great confusion of ideas seems to arise from confounding two separate and distinct subjects, the good of the service generally and the good of the members of the medical service.

Opinion is very much divided on the former, as to whether the late "combination" plan (of regimental and staff, for there never was a purely regimental system) or the recent "unification" scheme is the better; and till the latter has had a fair and continued trial, no decided verdict from experience can be given. But it is scarcely compatible with our knowledge of human nature to expect a fair trial of a new system to be carried out by men who suffer by the change. It is therefore necessary that the members of the department should be sharers in the benefit, if any, arising from it. "Increased duties and responsibility" ought not to be thrust on a gradually decreasing number of executives without some incentive to increased exertion; and if, as Mr. Hardy admits, we have always done our duty well as regimental officers, it must be made to our advantage to persevere in the same course under altered and adverse circumstances. That may be a low view, but it is the practical one. If we are to be a "staff", let us be treated as such, by increased pay and allowances, and total detachment from regiments to which now we are only attached for the purpose of supporting institutions in which we can no longer have any interest. As a satisfied and contented department we will work *con amore* any scheme which makes us so, but do not let us suffer whilst the experiment of finding out what is best for the service generally is being tried. If station hospitals and staff officers are best, let us have the one and be the other. If regimental hospitals and regimental officers are best, let us have them by all means. But do not let us personally bear the discomfort and disadvantages of both, without the benefits of either, till the question is decided.

There is no variety of opinion on the second subject, the good of the members, and the means of allaying the discontent of the service. Quicker promotion, earlier and better retirement, and a reasonable chance of reaching the highest rank of the department would suffice. But how can we be contented, whatever the system, when three-fourths of our service must be spent in the lowest grade, and our chance of

attaining the higher is so extremely small as to be scarcely worth calculating on? Promotion at twelve years service, a pension at twenty sufficient to induce retirement, and the administrative appointments tenable for only five years in each rank (the members of which should be equal), would restore the department to such a position as to lead a sufficient number of good men to enter it, and the question of an unification or other scheme would be a mere matter of detail, and minor grievances be unheard of.

In my estimation the old "combination" plan is the best for both medical officers and the service. As long as the regiment is the unit of the British army, it ought to be self-contained, complete in every respect, and it would be as reasonable to make the rest of the regimental staff part of a general one, as to make the medical officers solely members of a department when doing regimental duty. But if such should be found necessary for economy (I deny the efficiency), do not let the change be made at the expense of the officers by whom the saving is to be effected.

Yours, etc.,

A. M. D.

THE DISSATISFACTION IN THE ARMY MEDICAL SERVICE.

WHEN the Secretary of State for War mentioned, some nights since, in the House of Commons, that he had been deluged with pamphlets on the Army Medical Department, and referred to the want of agreement in the views of the writers, as expressed in them, he certainly could not have had in his mind, or have meant to make his listeners believe, that there existed any discrepancy among them regarding the causes of the prevailing discontent in the department. All the pamphlets that we have seen, agree in tracing the dissatisfaction among the Army Medical officers to the same sources, though this or that source of dissatisfaction may be put more prominently in one than in another pamphlet, according to the particular experience or feelings of the writer. The interference with the Royal Warrant of 1858, and the rescinding of the privileges which were granted in that warrant, were the *fons et origo* of the heart-burning among the medical officers which has never since been allayed, but has rather gone on increasing with increasing years. The mischief and distrust which resulted from the withdrawal of the status and rights which that warrant granted to the medical officers have been incalculable. None of the warrants or circulars which have been since issued have succeeded in undoing the harm, or in removing the sense of insecurity, which the breach of faith in cancelling certain of the provisions put forth in the articles of the warrant of 1858 gave rise to. A fresh addition to the list of pamphlets already published on the grievances of the Army Medical Department, entitled "Rough Notes on the Army Medical Department", which has just appeared, only calls attention to the same fact in other language. In this pamphlet may be found a short history of the legislative regulations bearing on the constitution and privileges of the medical branch of the army, from the year 1848 to the present time, together with an account of existing grievances, and some suggestions for their removal. As the Minister for War has himself admitted, in the House of Commons, that the discontent in the Army Medical Department is widely spread (and it would be difficult, indeed, for him to shut his eyes to the fact, considering in how many ways it has been brought to his notice); as in the next place there is a general agreement in respect to the principal causes of this discontent; it remains only that the various suggestions which have been put forth, with a view to secure a restoration of content, should be fairly considered. There is no lack of them for consideration. It is for the Secretary of State for War to decide, after consultation with his responsible advisers on such matters, what among the suggestions that have been laid before him can be accepted, and to what extent they can be acted upon, with due concern for the interests of the medical officers and the army at large: and we trust that there will not be any avoidable delay in a conclusion being come to on the subject. It is hardly possible to overstate the harm which must result from a large and important body of officers, such as those which form the medical branch of the army, continuing in a state of chronic sense of wrong having been done to them, of labouring under the sting of grievances unredressed, and of being subjected to other unjust treatment. The sooner this state of things is altered, and the department brought to a satisfied condition by just and reasonable concessions secured on a firm basis, the better it will be, not merely for the medical officers themselves, but, we may add, for all who are brought into official relations with them in the public service of the country.

NAVAL MEDICAL APPOINTMENTS.

CANN, Staff-Surgeon T., M.D., additional, to the *Ganges*.

COLAN, Fleet-Surgeon Thomas, M.D., to the *Albatross*.

COLQUHOUN, Staff-Surgeon A. G., additional, to the *Implacable*.

MEDICO-PARLIAMENTARY.

HOUSE OF COMMONS.—Thursday, April 22nd.

The Public Health Act.—Mr. SCLATER-BOOTH, in answer to Dr. Lyon Playfair, said he had no report from the medical officer of the Local Government Board on the practical efficiency of the Public Health Act, and therefore could not lay it before the House.

Friday, April 23rd.

Ashantee Honours.—Dr. LUSH asked the Secretary of State for War whether, having regard to the fact that in the distribution of honours and rewards after the Ashantee war, combatant officers were rewarded in the proportion of about one in three of those engaged, medical officers in the proportion of about one in nine, he would give some assurance to the House that in any contemplated or fresh distribution of honours to the army, such a grave disproportion would receive his attention with a view to its remedy.—Mr. STANLEY: In the unavoidable absence of the Secretary of State for War, perhaps I may be allowed to answer the question. It is considered that the medical officers engaged in the Ashantee Expedition have received their full proportion of the honours and rewards bestowed on that occasion, and I am unable to hold out any definite assurance with regard to any future proceedings.

Tuesday, April 27th.

Ventilation of the House.—Lord H. LENNIX, in answer to Mr. Cayley, said he believed that the plan of filtering air by passing it through cotton-wool had been found very successful, and there was no objection to supplying it to both Houses of Parliament, if this were necessary. At present, however, almost equally good effects were obtained by filtering the air through the finest cambric. The expense of changing to the cotton-wool would be £200 at first, and from £50 to £100 a year afterwards.

Medical Acts Amendment (College of Surgeons) Bill.—Mr. STANSFELD has given notice that he will, on the House going into committee, move that the House will consider the Bill that day six months.—Viscount SANDON will move the following amendments. After clause 1, insert the following clause (saving rights of the College to admit women to certain examinations). "Nothing in this Act contained shall deprive the said College of the right (if any) existing at the passing of this Act, or relieve them from the obligation (if any) existing at the passing of this Act to admit women to the examinations required for letters testimonial of the College, or for a qualification to be registered under the Medical Act, 1858, or to grant letters testimonial to any woman who has satisfactorily passed the examinations and fulfilled the other general conditions imposed upon persons seeking to obtain from the said College such letters, testimonial, or qualification."

Notices.—Mr. WHITWELL has given notice that, on the second reading of Mercantile Marine Hospital Service Bill, he will move that it be read a second time upon that day six months.—Mr. O'LEARY, on the second reading of the Medical Act Amendment (Foreign Universities) Bill, will move that it be read a second time upon that day six months.

OBITUARY.

ROBERT LAW, M.D.

DR. LAW, late Professor of Institutes of Medicine in the School of Physic in Ireland, died on Friday, April 23rd, at his residence, Merrion Street, Dublin, at the age of 77 years. Dr. Law was educated at the University of Dublin, of which he was a distinguished student, gaining high honours during his collegiate career. He obtained a scholarship in Trinity College in the year 1817, and graduated A.B. in 1819. He took his Bachelor of Medicine degree in the year 1822, but did not take higher degree of M.D. until 1857. He joined the King and Queen's College of Physicians in 1827, and was elected a Fellow in 1829, and served the office of Censor for several years. Dr. Law was an earnest and constant student of pathology and practical medicine, and contributed great numbers of papers to the medical journals and transactions of the various medical societies. His most remarkable contributions were those on Cirrhosis of the Liver and Lung. His papers on the administration of mercury by small and repeated doses contributed much to the advancement of the knowledge of the uses of that drug, and had a great influence in diminishing its excessive use. Dr. Law contributed articles on Hemoptysis and Pleurisy to the *Cyclopaedia of Practical Medicine*.

Dr. Law was elected President of the Dublin Pathological Society in the year 1858, and continued to take an active part in the Society's proceedings so long as his health permitted. His communications to the Society were always of an extremely original character, and tended much to raise the credit of the Society. He had made a collection of valuable pathological specimens illustrating these diseases, in which he took a special interest.

Dr. Law was elected Professor of Institutes of Medicine in the School of Physic in Ireland in the year 1841, in succession to Dr. Graves. He continued to hold this office until October 1873, when, in consequence of the failure of his health, he was compelled to resign. The College of Physicians accepted his resignation with great regret. Since the attack of illness in 1873, Dr. Law's health steadily failed, and he resigned all his public appointments, including his offices of Physician to Sir Patrick Dun's Hospital, Simpson's Hospital, and the Criminal Lunatic Asylum at Dundrum.

Dr. Law was much beloved by all who knew him. He was an elegant scholar and pleasant companion, and was not only an active worker for the improvement of his own profession, but also in the cause of charity of every kind.

UNIVERSITY INTELLIGENCE.

UNIVERSITY OF OXFORD.

THE NATURAL SCIENCE SCHOOLS.—In a Congregation on April 27th, a statute, the principal effect of which would be that the examinations in the Natural Science Schools would be held only once a year, and that honours might be obtained in different subjects at different times, creating, in fact, independent Schools of Physiology, Chemistry, and Physics, was thrown out, after a sharp debate, by twenty-five votes to twenty-three. The opposition was partly due to the fact that the complex character of the preamble had rendered amendments impossible.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on the 20th April, viz.:

Messrs. William Walker, L.S.A., Land's End, Lancashire; Alexander Cosgrave, Fairfield, near Manchester; Charles Edwin Smith, L.R.C.P. Lond., Preston, Lancashire; Thirkell Anningson, Burnley, Lancashire; Charles Wm. Buck, Settle, Yorkshire, and Arthur Richardson, Rusholme, Lancashire, students of the Manchester School; John James Barnes, L.R.C.P. Ed., Bolton; Charles William Bass, L.S.A., Barnsley, and Robert Alexander Jackson, Notting Hill Square, of University College; Edward Joseph Day, L.S.A., Woodyates, Dorset; Edwin John Gurdon, L.R.C.P. Ed., Colchester, and Henry Percy Potter, Denmark Hill, of St. Thomas's Hospital; John Rees, L.R.C.P. Ed., Dover, and John William Davies, L.R.C.P. Lond., Ebbw Vale, Monmouthshire, of Guy's Hospital; Thomas Murray Hope, L.R.C.P. Edin., Natal, and George Newton, Newcastle-on-Tyne, of the Newcastle School; Edward Houlbrook, L.S.A., Ilkley, Yorkshire, and John Benjamin Hellier, Headingley, Yorkshire, of the Leeds School; George Henry Haines, Woburn Place, of St. Bartholomew's Hospital; Frank Nankivell, York, of the Edinburgh School; James Stuart Orchard, M.B. Aberd., Salford, Lancashire, of the Aberdeen School, and Alfred Thompson, L.S.A., Spilsby, Lincolnshire, of the London Hospital.

The following gentlemen passed on the 21st April.

Messrs. Joseph Bourne Waterhouse, Burslem, Staffordshire; Frederick William Richard Romano, L.S.A., Brazil; John Morrison Hobson, L.R.C.P. Lond., Forest Hill, and Alfred Rawlings, L.S.A., Plympton, Devon, students of Guy's Hospital; Thomas Porter Greenwood, Easton, Northamptonshire; Leander Starr Jameson, Earl's Court Road, Kensington, and Henry Algernon Hodson, Bishop's Stortford, of University College; Eugene Crétin, L.S.A., Mauritius, and George Roger Tasker, Lancaster, of St. Bartholomew's Hospital; David Valentine Rees, Camarthen, and Frederick Treves, L.S.A., South Hackney, of the London Hospital; Frederick Daniell Miller, L.S.A., Streatham, of King's College; John Aspinall Hunt, Ackbrook, Derbyshire, of St. Thomas's Hospital; George Gosset, B.A. Cantab., of the University College and Middlesex Hospitals; John Thomas Graham, M.B. Glasg., Tottenham, of the Glasgow School; Samuel Edgar Martin, M.D., Queen's University, Ireland, Newry, co. Down, of the Belfast School, and Wm. Richardson Edmond, Swansea, of the Edinburgh and University College Hospitals.

The following gentlemen passed on the 22nd April:

Messrs. David Edwards, L.R.C.P. Lond., Mold, Flintshire; Charles Greenwood, Nether Broughton; and John Fleming Hartley, Thorpe Salvin, Notts, students of University College; George Weddall Bond, L.S.A., Fulham, Norfolk; and John Parkes Lockwood, New Hampton, Middlesex, of Guy's Hospital; William Mardon Beaumont, L.S.A., Oxford, of the Middlesex Hospital; William Hotson Cadge, Carlton Colville, Suffolk, of St. George's Hospital; William Romain Smith, Oxford, of King's College; John Duncombe Bell, L.S.A., Antigua, of St. Bartholomew's Hospital; and Edward Thornton Johnson, South Norwood, of St. Mary's Hospital.

The following gentlemen passed their primary examination on the 27th April:

Messrs. John Theodore Cash, Abraham Garrod Thomas, Ernest Aylward, James Milne Chapman, Vincent Wanostrocht, and Walter Smith Kay, students of the Edinburgh School; William Roger Williams, Gregory Stock, Frank Taylor, Thomas Chalmers Norton, and Arthur Henry Boissier, of the Bristol School; Alfred Edward Fitzpatrick, Walter Baugh Hadden, and Damer Harrison, of the Liverpool School; James Herbert Thorpe, Arthur Kimberley Scattergood, and William Smith Porter, of the Leeds School; Henry Frederick Bailey, and Richard Shalders Miller, of University College; William Barron Smith, and Robert Hunt, of the Manchester School; John Henry Barnard, and Alexander John James Johnston, of Guy's Hospital; Edward Stacey Norris, B.A. Cantab., of the Cambridge School; Evelyn Richard Hugh Pollard, of the Dublin School; William Henry Rean, of the London Hospital; and Albert Denthall, of King's College.

The following gentlemen passed on the 29th April:

Messrs. T. C. Eooth, Alfred Blackmore, George Kirby, T. H. Parke, and Edwin Jackson, students of the Manchester School; J. D. Grant, James Cooper, John Hassall, and C. E. H. Warren, of the Edinburgh School; Charles Green, T. G. Ainsley, and Mark Malvin, of the Newcastle School; John Bibby, L. W. Davies, and R. S. Wilson, of the Liverpool School; E. L. G. Gamble, S. P. Woolley, and F. E. Cockell, of St. Thomas's Hospital; R. G. Bailey, and J. W. Hinings, of the Leeds School; E. W. Pryce, and S. T. Plumble, of St. Bartholomew's Hospital; E. B. Granger, and A. C. Morton, of Guy's Hospital; Ernest Blacker, and H. G. Milner, of the Bristol School; F. G. Baker, of St. George's Hospital; E. H. Dumbleton, of the Birmingham School; and A. J. Smith, of the University College Hospital.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 22nd, 1875.

Barrow, John, Hilldrop Crescent, Camden Town.
Chadwick, George Richard, King's Lynn, Norfolk.
Lush, John Selfe, West Lavington, Wilts.
Makins, George Henry, Dacresfield, Walton-on-Thames.
Musgrave, Reginald Vernon, 39, Finchley Road.
Strickland, Arthur William, St. George's, Wellington.
Thomson, George William, Hemel Hempstead.

The following gentlemen also on the same day passed their primary professional examination.

Collier, Herbert, St. George's Hospital.
Ellis, Joseph Watson, St. Bartholomew's Hospital.
Farnell, Henry Dawson, University College.
Gillard, Clarence Richard, St. Thomas's Hospital.
Grimwood, John Joseph Wright, Guy's Hospital.
Heelas, James, University College.
Khan, Mirza-Hussein, St. Mary's Hospital.
Robertson, Frederick Freer Leslie, St. Bartholomew's Hospital.
Thompson, Harry Young, St. Bartholomew's Hospital.
Williams, Alfred Glover, St. Bartholomew's Hospital.

At the Preliminary Examination in Arts, held at the Hall of the Society, on the 23rd and 24th April, 62 candidates presented themselves; of whom 24 were rejected, and the following 38 passed, and received certificates of proficiency in general education—viz., in the First Class, in order of merit:

1. A. B. Lee. 2. J. P. Hardman, W. C. E. Taylor, and G. E. Wainwright. 5. H. S. Frakes. 6. C. B. Richardson and G. B. Wall. 8. J. R. Day, F. C. Fisher, and S. H. Lindeman. 11. C. F. Cuthbert and J. Whiting.

In the Second Class, in alphabetical order:

J. W. Aird, Isabella Bartholomew, H. A. Benham, A. Beverley, R. Brookes, J. F. Burnes, G. H. Dodson, A. W. M. Drew, R. E. Durell, R. H. Fuller, F. J. Grindon, St. V. L. A. Hammick, E. A. Harbord, B. A. Y. Jollivet, G. L. L. Lawson, C. A. McAnally, A. K. Morgan, J. N. Pogose, John Reis, T. S. Rogers, J. J. Rolands, A. Smith, C. A. Smith, E. A. Swithinbank, F. H. Villanueva, and H. Wakefield.

KING AND QUEEN'S COLLEGE OF PHYSICIANS IN IRELAND.—At the usual monthly examination meeting of the College, held on Tuesday, Wednesday, and Thursday, April 13th, 14th and 15th, the following candidates were successful for the License to practise Medicine.

Messrs. Frederick George Leslie Eagar, Charles Gabriel Maturin, Wm. Henry Sutcliffe, and George Hugginson Wilson.

The License to practise Midwifery was obtained by—

The above-named candidates, and Messrs. Matthew Smyth Blood and Arthur Sedgley Halan.

MEDICAL VACANCIES.

The following vacancies are announced:—

BETHLEM HOSPITAL.—Two Resident Medical Students.
BRADFORD INFIRMARY AND DISPENSARY.—Physician. Applications to be sent on or before June 12th.
BROADMOOR CRIMINAL LUNATIC ASYLUM.—Assistant Medical Officer. Salary, £200 per annum, with furnished apartments, coals, gas, and attendance.
CAMBRIDGE IMPROVEMENT COMMISSION.—Medical Officer for the Urban Sanitary District of Cambridge. Salary, £250 per annum. Applications to-day.
CHELTENHAM GENERAL HOSPITAL AND DISPENSARY.—Junior House Surgeon. Salary, £80 per annum, with board and residence.
EVELINA HOSPITAL, Southwark Bridge Road—Registrar and Chloroformist. Salary, £50 per annum.
GREAT YARMOUTH HOSPITAL.—House-Surgeon. Salary, £100 per annum, with furnished apartments, coals, gas, and attendance. Applications on or before May 12th.

HOUGHTON-LE-SPRING UNION.—Medical Officer for the Rainton District. Salary, £25 per annum.

KILCHREHAN AND DALARICH, Parish of—Salary, £80 per annum. Applications, on or before May 1st, to the Chairman of the Local Board.

LUTON UNION.—Medical Officer for the Workhouse. Salary, £30 per annum.

MILFORD UNION.—Medical Officer for the Collooney Dispensary District.

NEWMARKET UNION.—Medical Officer for Nos. 1 and 3 Districts. Salary, £85 per annum.

NEWBURY UNION.—Medical Officer for the Second District. Salary, £140 per annum. Medical Officer for the Fifth District.

NOTTING HILL PROVIDENT DISPENSARY AND MATERNITY.—Resident Medical Officer, with furnished apartments, coals, lights, and attendance. Applications on or before the 20th instant.

OLDCASTLE UNION, Crossahiel Dispensary District—Medical Officer. Salary, £100 and fees, with £15 as Sanitary Officer. Applications on or before May 4th.

PADDINGTON, Vestry of.—Medical Officer of Health. Salary, £300 per annum. Applications on or before May 4th.

QUEEN CHARLOTTE'S LIVING-IN HOSPITAL.—House-Surgeon.

SALOP AND MONTGOMERY COUNTIES LUNATIC ASYLUM.—Assistant Medical Officer. Salary, £100 per annum, with board and apartments. Applications on or before the 14th instant.

SCARBOROUGH DISPENSARY AND ACCIDENT HOSPITAL.—House-Surgeon. Salary, £120 per annum, with apartments, gas, and attendance. Applications on or before the 17th inst.

ST. GEORGE'S (Hanover Square) DISPENSARY.—Physician. Applications on or before May 8th.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Salary, £65 per annum, with board, lodging, and washing.

SPALDING UNION.—Medical Officer for the Gosberton District. Salary, £40 per annum.

STOW-ON-THE-WOLD UNION.—Medical Officer for the Loughborough District and the Workhouse. Salary, £50 per annum, and fees. Applications on or before the 5th instant.

SWINFORD UNION.—Medical Officer for the Tullamore Dispensary District. Salary, £100 and fees, with £25 as Sanitary Officer. Applications on or before the 4th inst.

TORBAY INFIRMARY.—House-Surgeon. Salary, £100 per annum, with board and lodging.

TORONTO ASYLUM, Canada.—Medical Superintendent. Salary, £411 per annum, with furnished apartments, fuel, light, and furnished table for family. Applications on or before May 15th.

TOTNES UNION.—Medical Officer for the Ninth District. Salary, £20 per annum.

WANGFORD UNION.—Medical Officer for the Lungay District. Salary, £90 per annum.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House-Surgeon. Salary, £100 per annum, with board, washing, and furnished apartments. Applications on or before May 3rd.

MEDICAL APPOINTMENTS.

Names marked with an asterisk are those of Members of the Association.

ABBOTT, George, L.R.C.P., appointed Assistant-Surgeon to the Central London Ophthalmic Hospital, *vice* C. N. Macnamara, M.R.C.S. Eng., resigned.

COOKE, E. M., M.R.C.S. Eng., appointed second Assistant Medical Officer to the Worcester City and County Lunatic Asylum.

COOMBS, Rowland H., L.R.C.P. Lond., appointed Assistant-Physician to the General Infirmary, Bedford.

DAVIDSON, David C., L.R.C.P. Ed., appointed Senior House-Surgeon to the Birkbehead Borough Hospital, *vice* E. L. Tandy, L.R.C.B. Ed., resigned.

JAMES, William D., M.R.C.S. Eng., appointed House-Surgeon to the Hull and Sculcoates Dispensary, *vice* F. R. Chapman, M.B., resigned.

RICHARDSON, John R., M.B., appointed House-Surgeon to the Torbay Infirmary, *vice* A. Nicholson, L.R.C.P. Lond.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths, is 3s. 6d., which should be forwarded in stamps with the communication.

BIRTHS.

ELLIOTT.—On April 20th, at Chichester, the wife of George H. Elliott, M.R.C.S., of a son.

DAVIDSON.—On April 24th, at 224, Union Street, Aberdeen, the wife of Alexander Dyce Davidson, M.D., of a son.

MARRIAGE.

ROBERTS—ALEXANDER.—On April 14th, at Pinkieburn, Inveresk, N.B., by the Rev. J. D. Campbell, D.D., uncle of the bride, Frederick T. Roberts, M.D., of 53, Harley Street, Cavendish Square, W., to Elizabeth Lindsay, second daughter of the Rev. W. Lindsay Alexander, D.D., of Pinkieburn.

MEETINGS OF SOCIETIES DURING THE NEXT WEEK.

MONDAY.—Medical Society of London. George Buchanan, M.D., L.R.C.P., will deliver the Annual Oration at 8 P.M.; subject, "Some Points of importance relative to Modern Hospitals".

TUESDAY.—Pathological Society of London, 8.30 P.M. Adjourned Debate on the Germ-Theory of Disease; being a Discussion on the Relation of Bacteria and Allied Organisms to Virulent Inflammations and Specific Contagious Fevers.

WEDNESDAY.—Obstetrical Society of London, 8 P.M. Adjourned Discussion on the Relation of Puerperal Fever to the Infective Diseases and Pyæmia. The debate will be resumed by Dr. Barnes.—Royal Microscopical Society, 8 P.M. Mr. H. J. Slack, F.G.S., "On the Relation of Angular Aperture to Surface-markings and Accurate Vision".

THURSDAY.—Harveian Society, 8 P.M. Mr. Teevan, "On Urinary Affections of Children".

OPERATION DAYS AT THE HOSPITALS.

MONDAYMetropolitan Free, 2 P.M.—St. Mark's, 9 A.M. and 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.

TUESDAYGuy's, 1.30 P.M.—Westminster, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Royal Westminster Ophthalmic, 1.30 P.M.—West London, 3 P.M.—National Orthopaedic, 2 P.M.

WEDNESDAYSt. Bartholomew's, 1.30 P.M.—St. Mary's, 1.30 P.M.—Middlesex, 1 P.M.—University College, 2 P.M.—St. Thomas's, 1.30 P.M.—London, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Great Northern, 2 P.M.—Samaritan Free Hospital for Women and Children, 2.30 P.M.—Cancer Hospital, Brompton, 3 P.M.—King's College, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.

THURSDAYSt. George's, 1 P.M.—Central London Ophthalmic, 1 P.M.—Royal Orthopaedic, 2 P.M.—Royal London Ophthalmic, 11 A.M.—Hospital for Diseases of the Throat, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—Hospital for Women, 2 P.M.

FRIDAYRoyal Westminster Ophthalmic, 1.30 P.M.—Royal London Ophthalmic, 11 A.M.—Central London Ophthalmic, 2 P.M.—Royal South London Ophthalmic, 2 P.M.

SATURDAYSt. Bartholomew's, 1.30 P.M.—King's College, 1.30 P.M.—Charing Cross, 2 P.M.—Royal London Ophthalmic, 11 A.M.—East London Hospital for Children, 2 P.M.—Royal Westminster Ophthalmic, 1.30 P.M.—St. Thomas's, 9.30 A.M.—Royal Free, 9 A.M. and 2 P.M.

NOTICES TO CORRESPONDENTS.

CORRESPONDENTS not answered, are requested to look to the Notices to Correspondents of the following week.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, in forwarding their Annual and other Reports, favour us with *Duplicate Copies*.

AUTHORS desiring reprints of their articles published in the JOURNAL, are requested to communicate beforehand with the printer, Mr. T. Richards, 37, Great Queen Street, W.C.

CORRESPONDENTS, who wish notice to be taken of their communications, should authenticate them with their names—of course, not necessarily for publication.

WE CANNOT UNDERTAKE TO RETURN MANUSCRIPTS NOT USED.

COMMUNICATIONS respecting editorial matters, should be addressed to the Editor: those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the General Manager, at the Office, 36, Great Queen Street, W.C.

ERRATUM.—In page 566, column 2, of last week's JOURNAL, "Handbooks for Medicines" should be "Handbook for Midwives".

MEDICAL EDUCATION OF WOMEN IN INDIA.

THE Indian Government state that they are desirous of every encouragement being given to ladies to study for a medical degree, in which case, it is observed by Dr. Furnell, they must attend the full curriculum of prescribed studies; but where the ladies themselves prefer the more limited and practical course of study suggested by Dr. Furnell, arrangements may be made accordingly, and, on the completion of the course of study, certificates can be given by the College authorities of the degree of proficiency acquired in each subject. The division of the course of study recommended by Dr. Furnell is approved, and the Government fully concur with the Surgeon-General and Dr. Furnell that, with the exceptions specified, ladies desirous of becoming doctors must be prepared to attend the courses of lectures with students of the opposite sex. The Government understand these exceptions to be midwifery and surgery, and one or two lectures in anatomy and physiology. By the adoption of the arrangement proposed by Dr. Balfour of allowing the ladies to attend the lectures given at the Lying-in Hospital by the warrant medical officer to pupil midwives, it would appear that no additional expense need be incurred on account of midwifery lectures. The Surgeon-General will report the expense which will be incurred for pre collegiate training and for separate lectures in surgery, anatomy, and physiology, during the course of three years' study referred to above. The expense involved in the case of any of the ladies determining to study for the degree of M.D. should also be stated. No fees will be required for the present from the lady students.—*Madras Mail*.

HASTINGS PRIZE ESSAY ON THE SURGICAL TREATMENT OF ANEURISM.—The General Secretary acknowledges the receipt of an Essay, bearing the motto "San Remo".

USE OF TAR INTERNALLY.

SIR,—Two communications on the use of tar having appeared in the BRITISH MEDICAL JOURNAL, I write to advise caution in its employment. I have a vivid recollection of the case of a gentleman who, after taking tar pills for a considerable time to relieve chronic cough, was seized with peritonitis and obstruction in the bowels. The treatment employed was useless in obtaining any mitigation of his sufferings; and he died in the course of a few days. No post mortem examination was made, but the suspicion was very strong that an accumulation had occurred, and obstruction at the ileo-cæcal connection when pain was first complained of. I am, etc., L. H.

WE have not received the communication to which Dr. Huntley (Jarrow-on-Tyne) refers.

G. W.—The BRITISH MEDICAL JOURNAL can be sent to foreign countries on payment of the additional postage.

SIR,—Can you inform me, from recent sanitary reports, as to what is the present condition of the health of Hastings and St. Leonard's? A lady who is desirous of taking change of air at one or other of those places, has been warned not to do so, as "small pox is raging in the place". Possibly a member of the Association residing either at Hastings or St. Leonard's, might be good enough to give me some information.—I remain, Sir, truly yours, H. B. D.
London, April 27th, 1875.

NOTICES of Births, Deaths, Marriages, and Appointments, intended for insertion in the BRITISH MEDICAL JOURNAL, should arrive at the Office not later than 10 A.M. on Thursday.

PREVENTION OF QUACKS.

SIR,—I was very pleased to read the letter of Dr. D. A. O'Sullivan, in your last issue of the BRITISH MEDICAL JOURNAL, concerning the prevention of quacks; but I am afraid it would be money thrown away to appoint consulting medical law officers when the present state of the law will not allow conviction. It appears to me that the first thing to do is to endeavour to bring unqualified practitioners, bone-setters, and the various self-called professors, within the limits of the law. I would like to ask your readers if they know of any case like the following, in which a man has been fined or imprisoned. A man, with a fracture of the leg, goes of his own will to a bone-setter. The bone-setter orders poultices, and leaves the leg without splint or bandages; the bones protrude through the skin, and afterwards mortification sets in, and the man has to have his leg amputated. Now, if a case like this is unable to obtain redress at the hands of the law, how much good would the profession obtain by a legal adviser?

This matter of the suppression of quackery has been ventilated in the *Students' Journal*; but I believe nothing has been done concerning it lately. When quackery was spoken of in this JOURNAL, the one portal system was combined with it, which I think was a mistake, as I believe many are against this; but I think no medical man would be against the suppression of quacks. The law which seems to me to be able to meet all cases of unqualified practice is this: "That any person, male or female, who visits, prescribes, or in any way treats a patient for a disease, and receives in return an acknowledgment for any advice given to man, woman, or child, suffering from disease, should be liable to a fine or imprisonment as the case deserves."

If it be desirable to omit midwifery, I would say, make a law requiring every man or woman who does not obtain a qualification to practise to sign a proper paper, stating where he has received his or her information from, to justify their undertaking the charge of a lying-in woman, and then have a register kept, and, in case of neglect or ignorance, have their name struck off the list.—I remain, yours, etc., ONE WHO WOULD WISH TO SEE QUACKERY ABOLISHED.

SIR,—I cordially agree with Dr. O'Sullivan's suggestion. With regard to funds, let each member of the Association be asked to subscribe five or ten shillings. If the same energy be shown in this (a question of vital importance to the profession) that has been shown lately in the pages of the JOURNAL over the trivial matter of our titles, we will soon boast of a protection society. I enclose my *carte*, and remain, yours truly, A MEMBER WITH HOPE.

NORTHWOODS ASYLUM.—We are requested to state that this well-known institution for lunatics has passed into new hands. Dr. Reginald Eager, the late Medical Superintendent of St. Luke's Hospital, and Mr. Seymour, the late Secretary of the same hospital, have become the conjoint proprietors. The experience of these gentlemen is a guarantee that the future management of the Asylum will be thoroughly efficient, and we wish them every success.

SIR,—In your abstract of the remarks I made at the Royal Medical and Chirurgical Society on Mr. Acton's paper on April 15th there are a few corrections required. In page 524, 27 lines from bottom, the number should be "10,000", instead of "1,000". In line 21 from bottom, instead of "secondary", "primary" should be inserted. In line 19, "1870", instead of 1873; and the sentence in lines 9 and 8, commencing "Before the Acts", to convey my meaning should have stood, "During the same period, the average of gonorrhœa at Aldershot had been 95 per 1,000; but by similar corrections it would be reduced to about 75."

In my letter in reply to Dr. Nevins, in the last column in page 527, the year in lines 14 and 10 from bottom should be 1872, instead of 1873; and in line 12, "now" should be "never". In page, 528, line 11, instead of "question", insert "operation".—I am, yours, ROBERT LAWSON, Inspector-General.

DR. TILT'S paper on "Lymphangitis in Pelvic Pathology" will be found in the recently published volume of the *Transactions of the Obstetrical Society of London*.

COMMUNICATIONS, LETTERS, ETC., have been received from:—

REMARKS ON LEAD-POISONING IN LEAD-MAKERS:

WITH PARTICULARS SHOWING THE OPERATIONS BY WHICH THE
POISON IS INTRODUCED INTO THE SYSTEM, AND THE
SYMPTOMATIC DISTURBANCE RESULTING THEREFROM,
IN TWENTY-FIVE CASES.

By J. S. RAMSKILL, M.D., F.R.C.P.,

Physician to and Lecturer on Medicine at the London Hospital, etc.

IN consequence of there being in the east end of London several factories in which whitelead is made, many persons suffering from lead-poisoning contracted in these factories apply for treatment at the London Hospital; this institution, therefore, affords many opportunities for studying plumbism.

We have been unable to obtain the number of out-patients who have thus applied; but find that sixty patients with well marked symptoms were admitted into the wards of the hospital during the last two years. Of these, thirty-three were males, and twenty-seven females. Of the males, nineteen were aged from twenty to thirty, eight from thirty to forty, and only seven were over forty. The fact that the largest number attacked were under thirty, would seem to indicate that the men are unable to work for a long period in such factories without suffering, and not a few of them becoming incapacitated. Of the twenty-seven females, three were under twenty years of age, nine from twenty to thirty, eleven from thirty to forty, and only three over forty. From these particulars, it might seem at first sight that the females are able to continue the work longer than the men; but inquiry on this point led us to think that the women do not generally begin the work so early in life, and, therefore, the men attacked are younger, because they are employed at an earlier age. The women employed, judging from their statements to us, seem to resort to this occupation when they have failed in their endeavours to obtain other work.

We were anxious to know the operations by which the poison is introduced, and its effects on the system; and, therefore, obtained from a number of patients (twenty-five) particulars of their work and symptoms. We then learnt that some of them had been employed in what are known as "the stoves", where the carbonate of lead is dried. Others had been engaged picking out of the tanks the pieces of metallic lead, which had escaped the action of the acid; these pieces at the time of removal were lying amongst the newly formed soft carbonate, consequently the pickers' hands were necessarily more or less smeared with the carbonate. Others carried the freshly made whitelead from the tanks to the drying stoves; but it would seem that this part of the work is not so injurious. The persons who attend to the drying at the stoves, and those who carry the dried whitelead from the stoves to the warehouse are most frequently attacked, suffer soonest, and commonly have to discontinue their work. In these stove operations, the whitelead, after drying, is powdery and easily shaken about, and the atmosphere around the workpeople who lift and remove it is consequently more or less charged with its particles. This finely divided substance may, it would seem, enter the body by respiration, or by mouth and swallowing, or become intimately mixed with the clothing, and thereby brought into contact with the skin, especially of the hands and face. The persons who remove this dried powdery lead in trays from the stoves are mostly women; and they carry the trays on their heads; consequently, in lifting them up and carrying them along, they must necessarily shake some of the powder in the atmosphere they are breathing.

One woman who had been thus engaged, said that she was first employed in a lead-factory three years ago. She then worked four weeks, not every day, because she found she was unable, but "on and off only" about three days a week. After the first three or four days, she got "queer pains all over;" and, at the end of a month, was compelled to leave work on account of "drop wrist". About twelve months afterwards, she returned to the same employment, continued at it five weeks, and then was again obliged to leave it because of "drop wrist". A third time, she returned to this occupation of carrying about a month before she came to the hospital, and she said that, after working three weeks "on and off", the last day being in the stove department, she found one morning that she had no use in her wrists; she felt exceedingly weak, and had pain in her limbs. When seen at the hospital, at the time she gave this history, the "drop wrist" was very marked.

Another woman said she was employed as a carrier for about twenty-

four days, and was then obliged by illness to leave her work. She was laid up for three months, and seemed to have had well marked symptoms of lead-poisoning. She returned to the employment; and a second attack came on, for which she applied for relief. We found that she had a very evident lead-line on the gums, and other decided symptoms of plumbism.

A third woman said she first worked in a lead-factory three years ago, but not continuously; she usually "washed the pots". After being thus employed four months, she was attacked with lead-colic. On recovering, she returned to the work; and, after three months, a second attack compelled her to absent herself. She went again to the same employment, and a third attack, for which she applied for treatment, followed. She had the usual well marked symptoms.

A case illustrating the way in which the stove attendants suffer, occurred in a man, aged 26, who had previously been a dock-labourer, and had good health. He said he first worked in a lead-factory four months before he came to the hospital; he was employed in "the stoves". After working one week, he began to vomit frequently, and always felt sick; at the end of two weeks, he had "colicky pains" like cramp; in the fourth week, he had to be carried to a doctor, because he was doubled up with pain in his abdomen, and he was very tremulous and felt weak. He also said that, during the month he was thus employed, he did not work more than four days in each week; his bowels were constipated, and he was advised by his fellow-workmen to take aperient medicine. Diluted sulphuric acid was placed in the works, and all the workpeople could use it if they wished, but he remarked that he never found it of any service to him. Three months elapsed from the time when he left the factory to his admission in the hospital, during which he lost the use of the extensors of the wrist; he had great pain in the abdomen, was troubled with giddiness and extreme weakness, and he became very pale and lost a deal of flesh. In this patient the blue line was well marked.

One more case may be mentioned as showing the injury arising from the lead-picking above alluded to. A woman, aged 40, said that, five weeks before she came to the hospital, she for the first time worked in a lead-factory. During the first and second weeks, she worked full time; in the third week, she worked only one day, and was obliged to leave on account of severe pain all over the abdomen; she felt sick and vomited, and was extremely weak. When seen by us, the blue line on her gums was very distinct, and she complained much of pain in the limbs. She further told us that, according to the custom of the factories, she took aperient medicine once or twice every week whilst at work. She had in her occupation to pick the blue lead out of the tanks, and in doing this she must of necessity move about the powdery white-lead amongst which it was concealed.

On taking an average, founded on the statements of these twenty-five patients, the women, it seems, were attacked after working in a lead-factory about four months, and the men, two years; the period varying according to the individual occupation; and, from what we could learn, the earlier suffering of the women was due to the fact that nearly all of them were employed in the more injurious occupations of carrying and otherwise moving the dry powdery lead. Some men, suffering from lead-poisoning, said that they had been employed for many years, one even twenty-seven years, without suffering greatly; but they had worked amongst the blue, that is, the metallic lead.

We next endeavoured to ascertain the symptomatic phenomena which first revealed the lead-poisoning; and, to our minds, the symptoms were instructive, for we soon learned that poisoning by lead is generally attended by symptoms very similar to what occurs in other forms of poisoning. The patients, almost at the outset, become troubled with pain in the limbs and abdomen especially; and weakness with a feeling of great lassitude was an early and very common symptom; they frequently felt sick and often vomited, and constipation was usually an early trouble, for which they commonly took some aperient medicine, seemingly with relief. Not a few of the patients had an appearance which at once suggested lead-poisoning; the face had a dirty yellow or sallow colour; they were generally a good deal wasted and walked feebly, and more or less bent forwards; some of them were so prostrate that they moved with difficulty, and seemed to avail themselves of any opportunity to sit down. Pain and weakness seemed to be the most common and most distressing symptoms; in some the pain was confined for the most part to the abdomen, and although a few had, at the time they applied for relief, severe paroxysmal pain, so-called "lead-colic", in the majority it was not so urgent, but rather of a dull, wearing, constant, aching character. Together with the abdominal disturbance, the patients usually complained of pains in their limbs, and, in some of them, it was confined to these parts; this was chiefly in the joints in many cases, and in others it seemed to be disseminated through the muscles as well. In one case especially, the pain was

referred to the bone, and so localised seemingly in the tibia, that it was thought by some there might be periostitis; this patient at the same time had "drop wrist" and an exceedingly well-marked blue line on the gums. Some of them complained of pain in the head, and occasionally this symptom was very distressing. We have referred above to the characteristic cachectic appearance that is usually observed in these patients, but this was not well marked in all. One patient in particular had not this colour, but his skin was exceedingly pale, and it was instructive to notice that, after he had been in the hospital two or three weeks, this pallor had much diminished, and his aspect was even then much healthier. Nausea and vomiting were also very frequent symptoms, and several suffered with constipation, but usually the bowels acted regularly under the influence of drachm-doses of sulphate of magnesia. Tremor was a common symptom; this brought forcibly to our minds how closely the condition resembled fever; and with this tremor there was usually a great deal of weakness, and a very agitated manner on movement.

With a view to show the symptoms and their frequency, we append the following summary, in which the particulars of twenty-five cases (fourteen males and eleven females) are given. There was in twenty, pain in limbs, or joints, or "all over"; in twenty, colic, severe, or dull aching pain; in eighteen, vomiting; in seventeen, blue line on gums, very marked; in seventeen, tremor, very great in some; in fifteen, constipation; in fourteen, marked cachexia; in fourteen, great weakness—extreme prostration in some; in eleven, loss of appetite; in eleven, loss of muscular power, or "drop wrist"; in ten, thirst, sometimes excessive; in nine, foul taste in the mouth; in nine, nausea, not necessarily vomiting; in six, headache; in six, wakefulness; in five, wasting; in five, stranguary; in four, frequent micturition; in three, delirium; in three, offensive breath (probably more frequent); in three, fainting; in two, giddiness; in two, dimness of sight; in one, loss of voice; in one, swelling of the body.

The treatment adopted in most of the cases was, removal from the source of the poison, confinement to bed to a great extent until the most urgent symptoms had subsided, light food, such as milk, broth, etc., quinine and sulphuric acid in some cases, and in others sulphate of magnesia followed by iodide of potassium. With this treatment, the average duration in hospital was as follows. Of the sixty patients, twenty-nine were discharged "cured", on an average within nineteen days; eighteen were discharged "relieved", within twenty-seven days; ten remained under treatment at the time we took these notes; one contracted fever, and was removed to the Fever Hospital; and two died.

The two who died were both young women, and sisters. One was brought to the out-patients' department; she seemed very ill, confused, and with stupor to such a degree, that she was unable to give any clear statement as to how she had suffered, but she said she had had a great deal of pain in her head, and her sister, who accompanied her, told us she had had fits in which she lost her senses; these were evidently epileptiform. She had for some weeks worked in a lead-factory, but, her health failing, she was obliged to leave it, and the fits came on. It was found she had a well-marked blue line on her gums, but it was recognised at the time that she might be an epileptic, and the seizures and lead-poisoning might coexist without their having any relation of cause and effect; and inquiry showed, that she had, when very much younger, suffered from fits, but, as far as we could gather, she had been free of them for years until she went to work in a lead-factory. This patient's heart, lungs, abdomen, and urine were examined, but there were no signs of chest or abdominal lesion. She was taken into the hospital, and next day she died. The necropsy showed that the viscera were healthy looking; the spinal cord was also examined microscopically, and no morbid change was discovered. A large portion of the brain was analysed, and Dr. Tidy reported that he discovered lead in its substance.

Within a few days of this patient's death, the sister above referred to, who had also worked in a lead factory just previously, was admitted into the hospital, and she, too, rapidly died with epileptiform seizures. The lead-poisoning in these cases would seem to have determined the later fits and death.

THE ROYAL SOCIETY.—The following gentlemen have been selected by the Council from the fifty-four candidates for election to the Fellowship of the Royal Society:—W. Archer, M.R.I.A.; J. Risdon Bennett, M.D.; D. Brandis, Ph.D., F.R.S.; J. Caird, C.R.; Professor J. Casey, LL.D.; A. Dupré, Ph.D., F.R.S.; J. Geikie, F.R.S.E.; J. W. L. Glaisher, M.A.; J. B. N. Hennessey, F.R.A.S.; E. Klein, M.D.; E. Ray Lankester, M.A.; G. S. Nares, Capt. R.N.; R. S. Newall, F.R.A.S.; W. C. Roberts, F.R.S.; Major-General Scott, R.E., C.B.

ABSTRACT OF THE LUMLEIAN LECTURES ON LIFE, AND ON VITAL ACTION IN HEALTH AND DISEASE.

Delivered at the Royal College of Physicians, London.

BY LIONEL S. BEALE, M.B., F.R.S.,
Physician to King's College Hospital.

LECTURE III.

ONE of the most remarkable examples of inherited constructive power is the bioplasm of the spermatie particle. The bioplasm of a human spermatozoon, which, perhaps, hardly weighs as much as the one-hundredth part of a single red blood-corpuscle, may stamp with unmistakable individual characteristics several tissues and organs which, in their fully developed state, weigh many pounds. Moreover, the influence of the power thus conveyed extends over many years, and is as distinctly manifest in the action as in the structure of tissues. This influence may not be clearly evident until many years have passed since the minute particle of bioplasm left the organism that produced it. But how are we to explain the association of such far-reaching constructive power with molecules of such minute size? No properties of any elements that have been discovered are in any way comparable with those manifested by this wonderful particle. Mr. Darwin has, therefore, endeavoured to explain the marvellous properties in another way.

It is suggested that living spermatozoon may be composed of particles detached from every component element of the tissues of the parental organism, passing from every part of the body where they were formed, and moving with unerring precision towards the gland-tubes, where they collect together in sets without confusion, thus to form the spermatie particle. By what means these millions of particles find their way to their proper destination—how they are sorted, how at last they arrange themselves in proper order, has not even been suggested. But, further, it is not stated from what part of the cells the particles are supposed to come. Now, the anatomical elements are complex, and many are composed of several kinds of matter. Many are growing, and the matter of which they consist is in very different states in different parts at different periods. If non-living particles were to collect in the manner assumed, it is not conceivable that such a collection could in any way have vital powers communicated to them. On the other hand, if we assume that the minute particles are detached from the bioplasm, we should have to assume that minute particles of bioplasm passed through even the thickest and hardest formed material in a direction the opposite of that in which nutrient fluid was flowing. We must further conceive such living particles as making their way into the intercellular spaces, and directing themselves, or being drawn, into the blood-vessels or lymphatics, or working their way through the tissues in the most direct course towards the seat of their development. By what means they find their way, why they do not take up nutrient material and grow so large as to be stopped in their course, how it is that many are not lost and impacted in growing parts, it is impossible to conjecture.

It has been suggested that a general directing agency might be influential in regulating and governing the phenomena contemporaneously proceeding in all parts of a living body which result in the formation of very different structures, somewhat as a number of workmen are controlled and directed by a central authority placed over them. Certainly, the facts of the case do seem to demand some such postulate; for, as each part grows and undergoes development, changes occur in other parts not anatomically connected with the first, but otherwise related, though separated perhaps by a considerable distance. But there is, in fact, no centre from which such power could act, and there are no means by which it could be conceived to operate upon tissues at a distance. I cannot even admit that any facts known to us justify the belief that one cell is capable of acting upon adjacent cells. I do not believe that any particle of living matter is capable of influencing the phenomena of any other particle, except perhaps by taking up more than its own share of pabulum, in consequence of an unequal distribution.

It will be asked, How, then, are the facts to be explained? If the

development of any particular tissue be carefully studied, as may be done by comparing specimens taken at different stages of growth, the observer will be able to form a conception of the phenomena which succeed one another in an orderly manner, until, in place of the bioplasm-particles of the embryo, he finds a highly elaborate arrangement of parts performing a definite office. At first, all that is to be seen is a number of masses of bioplasm which divide and subdivide. After the process of multiplication has continued for a certain period of time, each portion of bioplasm undergoes change upon the surface, and produces formed material. The arrangement and shape assumed by each particle will, in some measure, be determined by the growth of neighbouring masses, and the pressure that may be exerted, as well as by a number of other circumstances. The general form of the organ or tissue is determined chiefly by the inherent vital powers of each individual portion of bioplasm out of which it is formed, but in part by the growth of contiguous organs or structures. Whether the elementary part shall be drawn out like tendon, muscle, or nerve, flattened, many-sided or oval, like certain forms of epithelium, will depend upon its connections which were determined at a very early period, and whether it be subjected to stretching or pressure. Many questions, however, that might be asked with reference to many of the matters to which I have very briefly adverted cannot, in the present state of our knowledge, be answered, and are likely to remain unanswered for a long period of time. But I venture to think that, if scientific men substitute conjectures for answers, and confidently recommend to the public their own speculations as if they were scientific conclusions based upon evidence, it is the duty of other scientific men to examine the propositions, and to carefully criticise them. From what has lately fallen from some of those attached to the doctrine of evolution, it would almost seem as if they considered that their views were to be accepted by us without even the slightest examination. Against this idea, one cannot too strongly protest, and especially when one finds the most far-fetched hypotheses advanced and pressed upon the people as worthy of being accepted, and believed as actual truths.

BIOPASM IN DISEASE, AND THE DEGRADATION OF BIOPASM.—Having considered the changes taking place in simple living matter, and those wonderful phenomena which succeed one another with perfect regularity and in perfect order, until the formation of the organism, with its complex tissues and organs, is accomplished, let me ask your attention to vital phenomena of a different kind which result in degradation as regards formative power, although there is increase, not diminution of those changes to which I would restrict the term vital. If the bioplasm of man or one of the higher animals grow more rapidly than in the normal state, its power of forming tissue and of developing structure is impaired. If any structure whatever be produced, it is soft, incapable of discharging its function properly; it is weak, and it does not last. But, if the rapidity of the growth of bioplasm be very considerably increased, no tissue at all results. Bioplasm produced by descent from that which grows and multiplies quickly does not regain formative power. Rapid increase is associated with loss in constructive power; but vital activity is increased, if by the phrase we mean to imply that more pabulum undergoes conversion into bioplasm within a given time than in the normal state.

If the bioplasm of any tissue in a state of inflammation or fever be compared with that of the same tissue in health, it will be found that the bioplasm-masses have considerably increased in size. The essential change, both in inflammation and in fever, seems to be *increased nutrition of bioplasm*. An inflammation may be regarded as a local or circumscribed fever, and a fever as a general inflammation. The growth of the bioplasm in ordinary fevers does not proceed far enough to end in pus-formation, because the general changes in the blood, in the nervous system, and in other parts of the body, cut short life long before the whole organism could pass into a state of general supuration; but how often do we find a sufficiently marked tendency to such a state in the extensive and too often wide-spread suppurations occurring in tissues and organs of persons who just escape death from severe attacks.

Now, what is the cause of the increased nutrition and growth of the bioplasm? In fevers and in every form of inflammation, the bioplasm suddenly, quickly, that is perhaps within a few hours, increases greatly in amount. It may divide and subdivide into several masses, all of which grow rapidly and take up a large quantity of nutrient matter. The production of formed material is not only for the time suspended, but much of the formed material last produced, and still in a soft and imperfectly developed condition, is taken up by the bioplasm which produced it.

What would happen if the living matter did not increase, if pus were not formed, and perhaps much tissue destroyed? Although the inflammatory process is undoubtedly destructive, the tissue destroyed

is as nothing compared with the amount of texture that would be totally destroyed by decomposition, if the phenomena of inflammation did not occur. The bioplasm-particle would die, and that regular flow of fluid to and fro in the very substance of all the tissues being deranged, the bioplasts near the part affected would also die, and the organic matter of these, with that of the tissue and organic matter present, would undergo decomposition. The resulting products would diffuse into the neighbourhood, and extensive mortification would ensue. The blood would stagnate in the neighbouring vessels; its bioplasm would die and undergo decomposition. In such cases, it often happens that the death of the organism very soon follows. If, however, a part of the body mortify, and inflammation occur around the dead tissue, life may be saved and the dead mass detached. But in this case there must be rapid growth and multiplication of bioplasm between the part that is dead and the healthy tissues.

If the bioplasm of any tissue be supplied with more nutrient material than it receives in the normal condition, it will grow more rapidly than usual. This increased growth, owing to an increased access of nutrient pabulum, is the *first change that occurs in inflammation, and it is essential to the inflammatory process*.

The more ready access of nutriment may be due to an opening in the formed material and exposure of the bioplasm at one point, as may occur in mechanical injury; or it may depend upon a softened state of the formed material, which is thereby rendered more permeable to the fluids; or the character of the nutrient fluid may be so altered as to permeate the formed material much more readily than the nutrient fluid which transudes through the walls of the vessels from healthy blood—a condition which is met with in some forms of inflammation, and in all the more severe forms of fever. But the access of pabulum could not determine increased growth, unless there were an active tendency on the part of the bioplasm itself to appropriate the pabulum and to grow. Bioplasm has within itself no power of regulating or controlling the rate of its growth. The conditions vary as regards every kind of bioplasm; and different forms of bioplasm differ greatly in their power of bearing a change in the conditions. Some forms will live under external circumstances of the most varied kind, and are, therefore, found over a very wide area. Others suffer or are destroyed if the external conditions be altered only so slightly as to be imperceptible to many living creatures. As it were between the two extremes, are forms of bioplasm that grow and deteriorate, but still live for years, under adverse circumstances, the structures formed never attaining a state of vigour. The weak succulent too quickly developed vegetation of our fern-cases is an example; and the soft rickety tissues of some of our weak, flabby, overfed, town-bred, highly precocious children, supply a very painful instance of too quick formation and growth. Is it not a mistake to point to such cases as examples of diminished vital action? It seems to me that life has been carried on too fast, and not too slowly. Too much pabulum has been taken up, not too little. Too much heat, too much food, favour a quick rank succulent spongy sort of development, inducing the formation of soft bones and weak imperfectly acting tissues.

The loss of formative power as the rate of growth and multiplication of the bioplasm increases is a fact of great interest. Bioplasm may form tissue and give origin to multitudes of bioplasts, from which tissue may also be developed. But the very particle of bioplasm which might have taken part in tissue-formation will, if it grow and multiply too fast, not only lose its power of forming tissue, but the particles that may be produced from it by descent will never regain the capacity that has been lost. No pus-corpuscle or any of its descendants ever takes part in tissue-formation. But, although formative power is lost, new powers or properties may be acquired. These are, however, remarkable for destruction; never for construction. Some forms of pus acquire a most wonderful capacity for rapidly growing and multiplying, as well as for living and resisting the influence of external conditions. The little offsets or particles that are detached from them may rise in the air, live for a time in water or milk, or other fluids containing organic matter, adhere to a sponge or probe or other substance, or be carried in a living state on the foot of a fly or some other insect, and thus transported to an organism at a distance from the one which was the seat of their production. The minute germs, being in contact with material adapted for their nourishment, rapidly grow and multiply in their new situation. As we know but too well, such forms of virus have been produced *ab initio*, fostered, and propagated to the destruction of hundreds of human beings. This particle of deteriorated bioplasm, which in some cases may be seen, is a "disease-germ", and of such "contagium" consists. It has been already shown that an ordinary form of morbid bioplasm, pus, often originates in the bioplasm of epithelium and in that of connective tissue, and that certain forms of pus have specific virulent properties, and are in fact animal poisons,

which may be inoculated. I do not, however, entertain the opinion that all contagious disease-germs spring from the bioplasm of epithelium or connective tissue. Some may come from white blood-corpuscles, or from lymph-corpuscles. But I do consider that many facts favour the doctrine, that the contagious particles concerned in propagating many of our most serious specific fevers have been derived from the living matter of man's body, and that they are not germs of fungi or bacteria of any kind whatever.

I have, since 1861, directed attention to the many insuperable objections to the acceptance of the bacterium and fungus-germ hypothesis of contagious fevers. It is asserted by some that bacteria are the active agents, or at least the essential concomitants, of almost every form of contagious disease. Others have expressed themselves clearly and forcibly against this doctrine. Others, again, seem to think that fungi may or may not be the active *materies morbi*. If, say they, contagium do not consist of actual bacteria, it is caused by bacteria, or bacteria constitute an essential condition of propagation, or they prepare the body for the reception of the contagium, or they make the pabulum upon which the contagium lives, or they are a stage in the development of contagium, or they are constant and necessary accompaniments of contagious particles. But, at the time when certain contagious matter is most virulent, no bacteria, or few or doubtful bacteria, are to be discerned, while as the bacteria multiply the specific properties of the poison become weaker, and, when the bacteria are growing rapidly and freely multiplying, its specific properties have disappeared. Again, it is assumed that there is a necessary connection between the development of bacteria and the formation of pus, although anyone can satisfy himself by observation that the living moving pus-corpuscle is destitute of bacteria-germs, while the dead inactive pus-corpuscle, or more strictly, the matter resulting from the death of the pus-corpuscle, is being devoured by them.

I must apologise for troubling you with so many remarks against any form of physical doctrine of life, but I shall trespass very little more upon your patience. If, by physics and chemistry, the phenomena common to all living—even in the case of the very lowest, simplest living—cannot be adequately accounted for, it seems to me it would be an idle waste of time to recount the numberless facts and arguments against the acceptance of a physical doctrine as applied to thought.

Have the supporters of physical doctrines been able to tell us what goes on when a nerve grows, what occurs when it acts, or the difference between the nerve matter of the nerve-centres and nerve-fibres when they are in a state of the highest activity and most complete rest? Have they shown us how a single nerve-fibre is formed in its position, much less accounted for the manner in which that inextricable interlacement of fibres characteristic of all nerve-texture is brought about? Have they proved how an odorous or a sapid particle influences the nerve, or the differences between the vibrations of the molecules of the nerves concerned in sight and hearing, or what happens when a nerve-centre receives an impression from the periphery, or transmits an impulse outwards—nay, have they advanced a plausible theory to explain how we are able to bring about a definite degree of shortening in muscular fibres, maintain it for a time, and vary it as we will? And yet we are expected to accept the dicta concerning the nature of the highest and most complex actions of man's organism, of authorities who are professedly unable to enlighten us as to the changes which occur when an amoeba or a bacterium moves, or takes up nutrient matter, grows, or divides and multiplies.

THE HIGHEST FORM OF VITAL ACTION: BIOPLASM OF NERVE.
—I venture to think that we may entirely dismiss from our minds every vestige of the notion that the action of any nervous apparatus is mechanical, or that any part of it can be formed by physics or chemistry. As far as I am able to learn, there is in every nervous action something behind that part of the process which is plausibly considered to be physical. Before the simplest reflex act can be completed, there must be a nerve-current, and the latter cannot be set free unless some chemical change occur. The matter undergoing this chemical change must be formed, and its particles must have been so arranged that the changes ending in the development of the nerve-current may occur. I am not one of those who regard the nerve-force as some mysterious and very peculiar form of energy, and am quite ready to accept the view that the current that passes along the nerve-fibre is electricity, or something very closely allied or related to it. I can conceive that many of the phenomena of the nervous system are a consequence of nutritive acts, and that the latter are, in their turn, controlled and regulated by nerve-action. I was, in fact, the first to describe the distribution of nerves to capillaries, and to point out that these form the afferent part of a self-regulating nerve-apparatus connected with the distribution of blood. There is, one may say, always a tendency to the derangement of the complex phenomena of the higher organisms; but this tendency

is compensated by the most elaborate and beautiful arrangements, of which the self-regulating nerve "mechanism", in connection with the distribution of the blood in the capillaries, is one of the most remarkable. All the nerves and nerve-centres, and other tissues of which this so-called "mechanism" is constituted, were gradually formed by living matter, and the action of this apparatus is due to the action of the bioplasm in connection with it; for, when the latter is deranged, the action of the "mechanism" is disturbed; if it cease for a time, the action is suspended, and, if the bioplasm die, the "mechanism" is destroyed. Vitality, therefore, comes into play in the construction of the apparatus out of bioplasm, and in the preparation of the substances, by chemical change, in which the nerve-current is established. But the actual nature of the nerve-current is only a very small part of the great question of the general nature of nerve-action. The nerve-current may be the same form or mode of force in all creatures, the different results effected by it in different animals being due rather to differences in the construction and arrangement of the nerve-apparatus of the organism than to differences in the current which the nerves transmit. But the development and arrangement of the nerves is entirely dependent upon bioplasm.

Whether the bioplasm which takes part in the development of nerve-fibres, and which is found in connection with the active part of all nerve-fibres, at every period of life, is concerned in receiving impressions, or whether this office is performed by the fine nerve-fibre only, is a question of great interest. In connection with all nerves forming the terminal expansions which constitute the essential part of sensitive nerve-organs, masses of bioplasm are numerous; and numbers are found in connection with the ultimate ramifications of motor nerves distributed to some muscular fibres which are highly active, like those of the diaphragm and tongue. In the case of some muscles, the terminal nerve-fibre is at certain points highly convoluted; and here we find the masses of bioplasm very numerous, and situated very near to one another. All these facts support the inference, that these masses of bioplasm are intimately connected with the action of the nerve-fibre as well as being concerned in its formation. On the other hand, there are very few upon the finest ramifications of nerve-fibres in the serous membranes, which become extremely sensitive in disease. It might, therefore, be argued that the pain results rather from pressure upon, or stretching of the finest nerve-fibres in the intervals between the bioplasts, than from any direct pressure or other influence upon the bioplasts themselves. Again, in the imago state of many insects, the finest ramifications of the nerve-fibres exhibit very few bioplasts in their course. The same remark holds good to a less extent with regard to the distribution of nerves to the involuntary muscles. At the same time, the peripheral ramifications of nerve-fibres are nowhere destitute of bioplasm. Probably one-hundredth of an inch is the greatest length of peripheral nerve-fibre in the higher animals which intervenes between two bioplasts.

I conclude then that, although the bioplasm is necessary to the peripheral expansion of nerves, it is not the material which is in all cases absolutely essential for the reception of impressions and their conveyance to distant parts. I think, however, there is little doubt that the bioplasm of peripheral nerves develops nerve-currents, feeble perhaps as compared with those set free by central nerve-cells, but yet of sufficient intensity to influence the nerve-centre. The peripheral nerve-bioplasm is also concerned, as has been already remarked, in the formation and renovation of the nerve-fibres. This change is constantly proceeding in all nerve-organs.

Another important change in which these bioplasm-particles, in connection with the peripheral expansion of nerves, probably take part, is the development of heat. Is it not possible that, under certain circumstances, the mode of force developed in the matter of the nerve-bioplasm may be changed, heat being rapidly produced instead of nerve-force? The suggestion at once occurs, whether the explanation of such exceptional cases of high temperature as that brought by Mr. John Teale before the Clinical Society a short time since, will not probably be found to have something to do with the phenomena of nerve-bioplasm.

BIOPLASM OF THE BRAIN.—Let me now endeavour to ascertain whether the phenomena connected with the operation of mind have their origin in bioplasm. The only instrument concerned in thought attains its highest state of development in man. In the formation and action of this organ bioplasm is all-important, and exists in greatest amount in that part which, upon other grounds, we know is concerned in mental action.

The highest form of bioplasm or living matter in the world is that which, as I believe, is concerned in mind, and this attains its highest state of activity not until the age when that part of the nervous apparatus concerned in mental operations has attained a high degree of

elaboration. This period differs in different races and in different individuals, but it is never reached until some time after growth has ceased, and every tissue and organ is fully developed. As far as I am aware, those parts of man's brain concerned in the manifestation of its highest mental faculties constitute the only structures in nature which continue to improve for many years after the rest of the organism has attained its highest state of development. So also these, above all structures, are remarkable for continuing to improve, although many tissues of the body may have been for some time undergoing deterioration and decay.

It is not easy to conceive by what means the angular cells, which form such prominent objects in the grey matter, could will. That these are concerned in the formation of the fibres is certain, and it is possible that in them nerve-currents may originate; but it is very doubtful whether the bioplasm of these cells is the bioplasm concerned in thought. There are other bioplasm-particles, and in enormous numbers, though they do not constitute such prominent objects as the angular or caudate cells. These are little spherical particles of bioplasm, many of which are smaller than a red blood-corpuscle, and are probably connected by communicating fibres of great delicacy. These bodies are situated near the surface of the grey matter among the ultimate subdivisions of the excessively delicate nerve-fibres. In this situation, the supply of arterial blood is more abundant than in any other part of the nervous system, and the particles of bioplasm in question being naked and unenclosed in any cell-wall at any period of life, are just such as we should expect would undergo rapid change. These are, I believe, the active agents which, by their movements, may act upon the delicate nerve-threads which ramify on all sides in very close proximity to them. When we examine these particles of bioplasm after death, they are spherical; but are we not justified in assuming that during life they may change in form, at least as much as a mucus-corpuscle or an amoeba? The slightest alteration in form would influence the current traversing the nerve-fibres that were close to them. These delicate bioplasts are, I believe, during the waking state continually undergoing changes in form. That in some situations they increase in number cannot be doubted, and it seems likely that collections might increase in extent even long after the formation of the brain had been completed. What is very remarkable is, that these bioplasts retain their primitive characters throughout life.

I daresay few persons will be persuaded to believe that the bioplasts concerned in the highest mental acts of man are bodies not more complex than the lymph-corpuscle or the white blood-corpuscle; but all evidence is in favour of the view, that exalted function is not dependent either upon complexity of constitution or upon quantity of material. There are no differential characters to be demonstrated between different forms of living matter having widely different endowments, by which the peculiarities may be accounted for. There may be differences in power not dependent upon differences as regards matter and its forces. May we venture to conclude that mind is the form of vital power which, stirring in these particles of bioplasm, causes the movement of the matter of which they consist, and that thus the elaborate mechanism slowly constructed and gradually brought to perfection is influenced? If this be so, mind is the highest form of vital power which exists in Nature, by which particles of matter are caused to move in a definite manner for a definite purpose.

CONSIDERATIONS ON THE TREATMENT OF NEW FORMATIONS OF BENIGN CHARACTER IN THE LARYNX.*

By LENNOX BROWNE, F.R.C.S. Edin.,

Surgeon to the Central London Throat and Ear Hospital, and to the Royal Society of Musicians.

THE introduction into medical practice of the laryngoscope, by Professor Czermak, more than sixteen years ago, opened up a new and even yet unexplored territory for observation and treatment—a territory equalled in importance by that of no other technical instrument for exploring the deeper cavities of the body. At first considered a mere physiological toy, this instrument has been proved, in a very short space of time, to be of immense power for good, and, it may be added, also for evil. It is, I suppose, an undoubted fact, that many more ophthalmic operations are now performed than previously to the discovery of Helmholtz. Certainly, the vaginal speculum and uterine sound have robbed of much wholesome fear surgical interference

with the cavity of the womb. But as the laryngoscope surpasses all these other instruments, by combining completeness of revelation with opportunity for precision of local treatment, so also has its reputation suffered in far larger proportion from excessive instrumental interference with the organ over which it holds sway. It is some years since Dr. George Johnson "felt it his duty to remark upon the possibility that the larynx may get too much of local treatment". Yet I fear that many who have quoted his warning have only done so to excuse their own overzeal in this respect.

Every sort of instrument has been introduced into the glottis, from the innocent brush to the cutting forceps or unguarded knife; and, while portions of the larynx itself, as the epiglottis or a vocal cord, have been bodily removed, one American laryngologist, on the other hand, has made, by intralaryngeal operation with the reflected light of the laryngoscope, a new vocal cord to replace one lost by disease. At least, such is the reported case. I am glad, for the honour of British surgery, to be able to state that these abuses of the value of the laryngoscope have, for by far the most part, occurred abroad.

In no department of practice with the laryngoscope do the foregoing remarks obtain with greater force than in that of the treatment of growths in the larynx; for, since Czermak, in 1859, first discovered, with the laryngoscope, a growth on the right vocal cord, and Lewin, eighteen months later, by aid of the same instrument, removed one, the goal of every student in throat-diseases has been to find an excrescence in the larynx, and, having found it, to remove it *vi et armis*, without for a moment considering how slight might be the symptoms he was attempting to relieve, or what serious results might ensue to his patient by the operative interference he adopted. I venture to think, therefore, that a few remarks with a view of inducing members of the profession to withhold their hands from efforts at mechanical removal of what is often, in every sense, a most benign formation, will not be considered inopportune or unworthy of attention.

The propositions I venture to submit for consideration are the following.

1. *Attempts at removal of growths from within the larynx are not in themselves so innocuous as is generally believed, but, on the contrary, direct injury of healthy parts, leading to fatal results, is by no means of unfrequent occurrence.*—I am quite prepared to give case for case in which this proposition could be verified; for I have knowledge of at least five instances in which perichondritis, or other equally fatal result, has followed as a direct consequence of intralaryngeal instrumental operations for removal of benign growths from the larynx. Nor is there much room for wonder at such a statement. However able a laryngoscopist the operator may be, he is, in ninety-nine cases out of a hundred, guided in his knowledge of the exact situation of the growth by previous examinations; and, when he operates, the larynx spasmodically closing around the instrument as soon as it passes the epiglottis, the growth is caught according to his skill, or, more often, according to his good fortune. But it is easy to understand how a piece of mucous membrane, the arytenoid cartilage, or one of the cornicula, may be caught and injured also. This is especially the case with the unguarded instruments now generally employed. Further, it every now and then occurs, that spasm of the larynx after an operation on a growth is so severe as to require tracheotomy. I have myself been called upon to perform it for such a reason.

2. *The functional symptoms occasioned by benign growths in the larynx are, in a large proportion of cases, not sufficiently grave to warrant instrumental interference.* Dr. Morell Mackenzie, in his exhaustive and elaborate essay on *Growth in the Larynx*, analyses the symptoms of nearly three hundred cases, one hundred of which occurred in his own practice, while the remainder were derived from every published source, English or foreign. From this analysis, it is seen that impairment of the voice is the unique symptom in about fifty-two or fifty-three per cent. of cases of growth. Pain is a very rare symptom. Cough, and not often severe, occurs but in twelve per cent. In two or three per cent., the sole sensation was that of "tickling". Difficulty of swallowing occurred in only eight per cent., and actual pain in swallowing was present in only one of these eight instances. In all these latter cases, the growths were attached to the epiglottis, and there could not be any objection to, or any difficulty in, their removal. These cases of glandular or fibrous growths on the epiglottis may, therefore, well be dismissed from further consideration as hardly coming within the scope of the present article. Dyspnoea was present in only thirty per cent., and dangerous dyspnoea in only fifteen per cent. In other words, as many as seventy per cent. of the cases were free from any element of danger whatever, and in eighty-five per cent. there was no serious danger to life.

It has, I am aware, been generally considered that mere impairment or loss of voice is in itself a sufficient reason for removing a laryngeal

* Read before the Medical Society of London.

growth; but this opinion has been, and is, held in the belief that intra-laryngeal operations are at least harmless, if not always successful, and few practitioners have hitherto thought it necessary to warn their patient that there was a certain amount of risk to life attending these operations, and that, in comparatively few cases, is the voice restored to its purity and entirety. The number of persons to whom the advice (appropriate to those subject to benign growths in other regions of the body) to watch and wait is given, must be very small; but, without doubt, there are a very large proportion which never require treatment, and, if left to themselves, never assume a serious aspect. For example, I have been the subject for the last four years of a small polyp on the left vocal cord, which renders my voice occasionally, but not uniformly, a little hoarse, and the text of "physician heal thyself", is not unfrequently preached at me. A French laryngoscopist kindly offered to remove it, but I hardly thought the symptoms sufficiently severe, and I have until now had no reason to regret having left it alone. Further still, there is no reason to doubt that, while many of these formations remain thus stagnant, a large proportion would, if untreated, "frequently disappear spontaneously, being subject, as they are, to slow atrophy and resorption" (Virchow).

3. *Many of these new formations will disappear or be reduced by appropriate local and constitutional medical treatment, especially when of recent occurrence.*—Before going further, I must premise that, except in the very rare and doubtful instances of a congenital growth, all these new formations originate as a direct consequence of hyperæmia, or, as Virchow puts it, "as the expression of an inflammatory irritation, which affected the whole surface, though it does not give rise to the same result in all parts". When growths are present, there is not unfrequently considerable general congestion of the laryngeal mucous membrane. It is, therefore, most important that every practitioner should make himself *au fait* with the use of the laryngoscope, and in every case of hoarseness examine the larynx of his patient at the very earliest date. Let him then treat the hyperæmia when it first occurs, and he will also see a new formation, should one arise, at its very commencement, or at least on the first approach of symptoms of its presence. It cannot be too strongly urged that the cause of a hoarseness is not to be discovered by pressing down the tongue with a paper-knife, and looking into the back of the mouth, and that a localised inflammation, ulceration, or irregular formation within the larynx, is not to be healed by swabbing the pharynx with a brush charged with solution of nitrate of silver, or by pushing a probang similarly loaded down behind the tongue, unguided by the mirror, in the vain belief that it is going into the larynx, when, in the one case out of ten in which it certainly reaches no further than the superior surface of the epiglottis, it as certainly finds its way down the gullet.

This is not the occasion, nor would space allow, to consider in detail the particular treatment best adapted for laryngeal congestion. It may be, however, stated that, in addition to the use of general and topical remedial measures to reduce the hyperæmia, the practitioner should remove any cause likely to keep up irritation of the larynx, such as a relaxed uvula, unsuitable occupation, or exposure to sudden changes of temperature, and rest of the voice should in all cases of hoarseness be strictly enjoined. I am not of opinion that frequent direct local applications with the brush are in any way necessary in cases of simple congestion of the larynx; but the moment the least irregularity of the cord is visible, the practitioner should at once make mineral astringent applications to the spot, daily until there is diminution of the growth or ulcer, and then on alternate days, or less frequently, as may be required. I know there is a great and general feeling in the profession against local laryngeal treatment, and much of this feeling may be something more than prejudice; but the case may be put thus. No ophthalmic surgeon would say that he would deem it necessary to himself drop solutions each night and morning into the eye of a patient suffering from simple conjunctivitis; but, were the case one of ulcer of the cornea or granular lid, he would feel justified in advising the patient to have the necessary topical remedies applied by himself or some other medical practitioner; and, if this be true of the eye, how much more is it of the larynx, where the part to be treated is not only hidden from the ordinary view, but where also some amount of technical skill is necessary to apply topical remedies with precision. I have seen many cases of neglected hyperæmia of the larynx, in which after an interval—sometimes only of a few weeks—a new formation has been seen to have sprung up, and such cases are not by any means necessarily associated with syphilis or phthisis. I have also often seen cases of small growths in which, by early local treatment, a distinct cure has resulted. The last under my notice, seen also by my friend Mr. E. Jewelyn Thomas, was that of Miss T., aged 19, who for three months had lost her singing voice, and for two months had been distinctly hoarse in ordinary

conversation. The condition, as seen with the laryngoscope at her first visit, is represented on Fig. 1, namely, a small growth on the left vocal cord surrounded by bright red localised congestion. In a week from the first application, February 3rd of the present year, the hyperæmia was removed. In a month, she was quite well. I saw her last week, and her voice was perfectly clear. Now, as to constitutional treatment, a word or two may be necessary; for, as I stated a few weeks ago, on the occasion of Dr. Drysdale's admirable paper on Syphilis, it is of the utmost importance in the case of syphilitic ulceration of the larynx, to combine local and constitutional measures, pursuing each with equal vigour and attention. Those who believe only in the local origin of these formations will probably be of opinion that all internal remedies are useless. It is certain, however, that syphilis, and, as I have little doubt, gout also, play an important part in predisposing to these local developments; and it may well be that medicines directed to counteract these dyscrasias are of good effect on the local condition; and so, I think, I have in some cases found them.

Fig. 1.

Fig. 2.

4. *Recurrence of laryngeal growths after removal per vias naturales is much more frequent than is generally supposed.*—Here again, as in illustration of the first proposition, numerous cases could be given in which the authors have been too quick to report their cures; and since the reports have been printed their patients have presented themselves either to their former attendant or to another with a return of their disease. Six per cent. has been given as about the proportion of recurrence after intralaryngeal removal. I would put it at 20 per cent., and two cases lately under my notice may be quoted as confirmatory on this point.

The first was that of Mr. T. F., a baker, who consulted me on October 22nd, stating that his voice had been always rather thick, having as a boy suffered from enlarged tonsils. He had within the last twelve months become hoarse, and was now almost voiceless. Until three or four weeks before coming to me, he had been for some months under the care of another practitioner, who had on eleven different occasions removed pieces of growth, and at the last two or three sittings he had informed the patient that there was the merest fragment left. There is in my mind not the slightest doubt that the practitioner stated the truth; but it should be mentioned that all this was not communicated to me until after I had examined the patient and made a drawing of his case (Fig. 2), when he exclaimed: "Why, that is just like the drawing made before I was ever operated upon." Regarding what I just now said as to constitutional treatment in these cases, it may be stated that this patient had contracted primary syphilis six years previously, followed by sore-throat and skin eruption, and was when I saw him suffering from palmar psoriasis. He had, however, received no medical treatment whatever from his former attendant, who told him that the eruption on his skin had no more to do with his throat than would a broken leg. Mr. Durham, who kindly saw the case with me, shrewdly remarked: "But you would think a broken leg had something to do with your throat if you had hurt both with one and the same accident."

The second case is that of Walter L., a hairdresser, aged 19, whom I first saw on the 3rd of March last at the Central London Throat and Ear Hospital. He stated that he had always been subject to catarrh, and, having lost his voice during an attack two years previously, had never since recovered it. He had attended for nearly a year at a general hospital, and only on his last visit had been examined with the laryngoscope. He had then attended another hospital, where, after removal of his uvula, pieces of growth were evulsed from his larynx on four different occasions, at intervals of from seven to ten weeks. The largest piece was that last removed. He stated that his voice was now worse than before any operation at all, and that lately his breathing had become laboured. He gave as his reason for discontinuing attendance at this last institution, that he did not see what was the use of these operations if the tumours grew larger at each interval. Laryngoscopic examination showed two pink lobulated and symmetrical growths on the vocal cords at their anterior insertion (Fig. 3). There was great thickening and irritability of the pharynx; the larynx was also ex-

tremely congested, and it was difficult to make even an ordinary examination. Although, therefore, I bring this case forward to show the strong tendency to fresh growth, even while under treatment, I cannot forbear expressing my opinion that the fact that any growth at all had been removed, reflects the greatest credit on the skill of the practitioner under whose care this patient had been.

Fig. 3.

It is worthy to be remarked that, where there is a tendency to fresh growth in another part of the larynx, or to recurrence in the original situation of the first formation, and repetition of operative procedures is made, the intervals between each successive recurrence almost invariably become shorter. This is, I believe, only what takes place in recurrence of tumours in other parts of the body.

5. *While primary malignant or cancerous growths are of extremely rare occurrence within the larynx itself, benign growths frequently assume a malignant or even cancerous character by the irritation produced by attempts at removal.* This proposition is to a large extent a corollary of the foregoing. Epithelioma commencing at the epiglottis or base of the tongue, or at the anterior wall of the œsophagus at its favourite spot just opposite the cricoid cartilage, often extends into the larynx; but it is most rare to find malignant disease commencing in the vocal cords or ventricular bands; that is to say, in the cavity of the larynx itself.* One of the points, however, strongly brought out by Mr. Simon and Sir William Jenner, and admitted by Mr. De Morgan in the great discussion on Cancer at the Pathological Society last year, was, that cancer may be induced in tissue previously healthy by mere irritation, such as that of a needle; this result being due, according to the two former authorities, to constitutional vice, and to the latter, to local development. Whatever the cause, this is what is often found in the case of growths of the larynx. I may allude to one such case (No. 87) in Dr. Morell Mackenzie's report of one hundred cases, which he, having treated during the life of the patient as benign, most straightforwardly included in his list of benign cases, though somewhat to the detriment of his statistics. I quote his remarks on the result of the *post mortem* examination. "The luxuriant growth of the new formation in this case pointed to its being otherwise than of benign character; and its microscopic examination illustrates the extreme difficulty of arriving at accurate conclusions concerning the histology of these tumours even when the entire growth is brought under observation. The specimen was examined by several eminent microscopists, and was at first supposed to be a simple papilloma. On another examination, fibrous tissue was found to be developed, and it was pronounced to be fibro-cellular. Still later, my brother, Mr. Stephen Mackenzie, discovered some nested cells (laminated capsules of Paget). From the extreme importance of this element, the case must undoubtedly be placed in the category of carcinomatous growths, and be considered as epithelioma. The whole surface of the growth was covered by papilloma." I was the more impressed with this case, because I saw the patient almost daily while he was under the care of Dr. Mackenzie, and he was for some months transferred to my sole charge.

6. *The instruments now most generally in use are far more dangerous than those formerly employed.* Success in removal of growths from within depends so much on the individual manual dexterity of the practitioner, as well as on the method of his examining the larynx and the plan on which his other instruments are constructed, that it is not surprising that well-nigh every practitioner who has attempted the operation has invented a new instrument for the purpose. As with tracheotomy-tubes, many such instruments have been adapted for one particular case, their utility lapsing with its termination. As to others, one wonders how they could ever have been expected to be of use at all. At first, every instrument—and, indeed, some more cautious

practitioners still confine themselves to such—was on the principle of a snare; and these were undoubtedly the safest. They are constructed more or less on the plan of a Gooch's cannula, and have been used by Dr. Walker of Peterborough, Sir Duncan Gibb, Dr. George Johnson, and others. The fault of them is that, while safe from injuring other parts, they are not well adapted for hard or large growths. Dr. Mackenzie's tube-forceps are a step further towards more instrumental freedom and strength.* Then came guillotines, rigid loops with sharp edges, fenestrated knives; and finally, in America, Germany, France, and England, common forceps, cutting forceps, and crushing forceps, strong enough to break a vesical calculus. Scissors, knives, guarded and unguarded, were also freely used. Galvano-cautery has been extensively employed abroad, but, happily for the patients, has not met with much professional favour for these cases in this country. As a curious evidence that even in Germany, where operative procedures are most boldly adopted, a feeling is dawning that it is possible to intrude too rudely into the larynx, it may be noted that Eyselle has recently suggested transfixing the growth by a needle passed through the thyroid cartilage from without: a procedure more easy in imagination than performance, and of little practical value. Dr. Jelenffy of Pesth has also, on the well founded belief that one does not see much of the larynx after the instrument has entered it, invented a very safe guarded *éraseur*, by which, as he states, first one side and then the other can be freely and safely swept of excrescences. Undoubtedly, the safest instrument is the guarded ring-guillotine of Stoerk, which combines strength, cutting power, and the maximum of safety against wounding healthy parts. I think I have good reason for stating that, since instruments were used unguarded, injury to healthy structures, and consequent perichondritis, have occurred more frequently than was formerly the case.

7. *The cardinal law, that "an extralaryngeal method ought never to be adopted unless there be danger to life from suffocation or dysphagia", should be applied with equal force to intralaryngeal operations; and it is a subject worthy of consideration whether, in many cases, tracheotomy alone might not be more frequently performed—*a. With a view of placing the patient in safety when dangerous symptoms are present; b. In order that the larynx may have complete functional rest; and c. As a preliminary step to further treatment, radical or palliative. If I have succeeded in proving the truth of my previous propositions, there is not much necessity for enlarging on this. I would simply beg once more to impress the importance of a more general study of the laryngoscope, and of its use at an early stage in every case of alteration of voice; of the early treating of hyperæmia of the larynx, remembering that it is the most general forerunner of growth; of the early and active local treatment of such new formations by topical astringent applications; of the administration of suitable medicinal remedies when there is evidence or presumption of any constitutional cause or complication; and of the non-instrumental interference with these formations for mere symptoms of inconvenience, having always in view the dangers that may occur to healthy structures, and the fear that irritation of the growth may only make the disease worse, rather than better. I have not discussed the question of thyroto-my, or division of the external cartilage of the larynx. Many of these operations have been done for reasons as little justifiable as some in which intralaryngeal operations have been adopted. Certain foreign practitioners have not hesitated to divide at one operation two or three rings of the trachea, the cricoid cartilage, the crico-thyroid membrane, the thyroid cartilage, the thyro-hyoid membrane, and even the hyoid bone, for removal of a small growth causing but little annoyance; and all this with apparently no thought of such a consequence as perichondritis or caries. In many cases where there is dyspnoea—the only symptom which appears to me to warrant interference capable of leading to fatal results—tracheotomy, whether as an only step, or as preliminary to other measures, should much more frequently be adopted. In making this suggestion, I am not unmindful of the fact that the operation of opening the windpipe is in itself a serious operation; but it is generally agreed that, in chronic diseases and in adult patients, the procedure is unattended with much risk to life. Amongst other advantages in the class of cases under consideration, it offers the chance of removing the growth from below—i. e., through the tracheal opening. Sufficient success has already attended this step to give encouragement to its more frequent adoption.

Looking at the many evil consequences likely to result, and actually resulting, from attempts at removal of growths from the larynx by the laryngoscopic or any other method, the profession generally will, I

* This statement was made originally as the result of my own experience, which comprises a personal knowledge of at least 20,000 cases of throat-affections, and in which I had only seen two cases of what was considered to be primary cancer in the larynx. A doubt having been suggested to me of the accuracy of my assertion, reference has been made to the works of Türck, Cohen, Mandl, and others: all are found to agree in the rarity of primary cancer of the larynx proper, and the extreme rarity of any form but that of epithelioma.

* Dr. George Johnson has recently been so good as to show me an arrangement, suggested by an ingenious patient, by which this form of forceps is rendered somewhat less liable to wound the mucous membrane.

trust, consider the proposition established, that there is not so commonly as is supposed any operative procedure for the treatment of these cases in which "no chance of danger is incurred".

MEANING OF THE TERMS DIPHTHERIA, CROUP, AND FAUX CROUP.

By SIR JOHN ROSE CORMACK, F.R.C.P.Lond., M.D.Paris.

IN my note on the History and Meaning of the Terms Diphtheria and Croup, published at page 544 of the JOURNAL of April 24th, I suggested that the prefixes diphtheritic, herpetic, spasmodic, and the like, are required so long as the word croup continues to be used by medical writers as a name for essentially different diseases. The propriety of this suggestion is illustrated by a criticism on my own statement in my paper, which is made by Dr. George Johnson at page 575 of the JOURNAL for May 1st.

He there says: "In the last number of the JOURNAL, Sir John Rose Cormack states that the spasmodic croup of English authors is the *faux* croup of the French. I have always believed, and I believe still, that the spasmodic croup of English authors is also the spasmodic croup of the French, its synonyms being laryngismus stridulus, crowing inspiration, thymic asthma." Dr. George Johnson adds, that "to speak of the *spasmodic croup* of the English as synonymous with the *false croup* of French writers is to introduce a new element of confusion into the discussion of the relations between croup and diphtheria". He says that the "*faux croup*" of the French is the "inflammatory croup" of English authors.

I correctly stated the meaning of the French term "*faux croup*". It is synonymous with our English terms "laryngismus stridulus" and "spasmodic croup". It is a "névrose", and not an "inflammation". I quote the following from p. 795 of the edition published in 1873 of the *Dictionnaire de Médecine et de Thérapeutique Médicale et Chirurgicale*, edited by Dr. Bouchut, Physician to the Hôpital des Enfants, and Dr. Desprès, Surgeon to the Hôpital Cochin.

"**LARYNGITE STRIDULEUSE, ou CROUPE SPASMODIQUE, ou FAUX CROUP.**—La laryngite striduleuse, maladie en apparence voisine du croup par l'âge des sujets où elle se montre, et par les accès de suffocation qui la caractérisent, n'est qu'une névrose du larynx greffée sur une laryngite aiguë."

"Une accès de suffocation apparaissant d'enlèvement, sans phénomènes précurseurs chez une jeune enfant endormi et bien portant, accompagné de toux sonore, avec conservation de la voix, également sonore et non croupale, disparaissant en quelques minutes ou en quelques heures, caractérisée le *faux croup* ou laryngite striduleuse."

It is evident from this extract that Dr. George Johnson errs when he says a "new element of confusion" is introduced by considering "spasmodic croup" and "*faux croup*" as synonymous. When I assert the synonymy of the terms, I only state a fact.

The following is from the *Manuel de Pathologie* of Professor Tardieu, p. 144.

"**LARYNGITE STRIDULEUSE.**—Syn.: *Faux croup* (Guersant); *angine striduleuse* (Bretonneau); *laryngite spasmodique* (Rilliet et Barthez). Le spasme du larynx qui constitue à proprement parler l'un des éléments de la laryngite striduleuse peut exister seul, et n'en diffère alors que par l'absence du catarrhe laryngien primitif ou concomitant."

The following is from the *Pathologie Interne* (vol. i, p. 300) of Monneret.

"**ANGINE STRIDULEUSE.**—Syn.: *Faux croup*, laryngite striduleuse, laryngite spasmodique.

"Spasme de muscles laryngiens; asthme de Millar, de Kopp; asthme thymique; spasme de la glotte; tétanos apicéno périodique; apicéno spasmodique; laryngisme infantile.—*Nature.* L'absence de toute lésion des voies respiratoires.....Tels sont les traits principaux de la névrose que nous étudions."

The following is from the *Dictionnaire de Médecine* of Nysten, edited by Littré and Robin.

"**FAUX CROUP.**—Syn.: *Pseudo-croup*; *croup spasmodique*; *laryngismus stridulus*... L'absence de inflammation," etc.

The following is an extract from the *Aide-Memoire* of Corlieu, the cram-book at present most in favour with the medical students of Paris.

"**LARYNGITE STRIDULEUSE, ou FAUX CROUP.** Pharynx et larynx à l'état normal, à peine rouges.....Ne pas confondre avec laryngite aiguë, ou laryngite pseudo-membraneuse, ou croup."

It will be observed that one of the mistakes against which the grinder warns the student is the mistake which Dr. George Johnson commits—the confounding "*faux croup*" with inflammation of the larynx.

In my former communication, I ought to have mentioned *laryngitis*, which most English writers call *croup*, but in which there is no false membrane.

I would add that my recommending the use of such explanatory prefixes as "spasmodic", "herpetic", and "diphtheritic", was merely an incidental suggestion of a simple means of giving lucidity and uniformity to the clinical descriptions of authors holding different views, and was not intended as a proposed reform in scientific nomenclature.

TRUE AND FALSE CROUP.

By JAMES RISDON BENNETT, M.D., F.R.C.P.,
Consulting Physician to St. Thomas's Hospital, etc.

It is not my wish to enter the lists in the interesting and important controversy now going on respecting the identity or non-identity of croup and diphtheria. But the criticism of Dr. George Johnson on Sir J. Rose Cormack's communication in the JOURNAL of April 24th, calls for notice. Dr. Johnson denies the accuracy of the statement that "the spasmodic croup of English authors is the *faux* croup of the French". This denial much surprised me, as, unless my memory deceived me, the term *false croup* used to be the common designation of the French for what has latterly been called by us "laryngismus stridulus". I, therefore, referred to Guersant, who, in the first edition of the *Dictionnaire de Médecine*, 1821, introduced the term *false croup*. In the second edition of the same work, 1835, art. *croup*, he thus speaks: "The name of *false croup* which I had introduced in the first edition of the *Dictionnaire de Médecine*, to supply the place of that of the acute asthma of Millar, which I thought ought to be abolished, because it has given rise to confusion and error, is certainly, as the critics have remarked, not very scientific; but my intention in proposing it was merely to associate a word which might be easily popularised with that of *croup*, which was already popular, and thus I wished to introduce into common language a distinction which I believe to be absolutely necessary. For the use of physicians, I shall more willingly adopt the expression of stridulous laryngitis admitted by M. Bretonneau" (Semple's Translation in Sydenham Society's *Memoirs on Diphtheria*, p. 210). The above passage is sufficient to prove that Sir John Rose Cormack's statement is correct; and also that Dr. Johnson is wrong, not only in his criticism thereon, but also in affirming that the "*laryngite striduleuse*" of the French is simply synonymous with the inflammatory croup of English authors. In reference to the latter term, however, it will, I think, be found that French authors employ it and the term *laryngismus stridulus* somewhat loosely. But Guersant, Bretonneau, and others certainly employ the term "*false croup*", stridulous laryngitis, "*acute asthma*", i.e., Millar's or thymic asthma (and, therefore, our *laryngismus stridulus*) as synonymous or nearly so. It is certain that Guersant, in the *Dictionnaire de Médecine*, second edition, speaks of "*laryngites striduleuses*" in the plural, and his first variety "*laryngite striduleuse simple*" is clearly our spasmodic croup, or "*laryngismus stridulus*". His second variety appears to be catarrhal laryngitis; and his third, I suppose, corresponds with Dr. Semple's "*laryngitis stridulosa*", or strictly acute inflammatory disease, but unattended with the exudation of false membrane. To a certain extent, therefore, Dr. Johnson may be right in affirming that *one* of the forms of the *faux croup* of the French is an inflammatory disease. In the new *Dictionnaire de Médecine et Chirurgie*, it is distinctly stated that under the term *croup* the writer comprises only those acute diseases of the larynx which are attended by pseudo-membranous exudations. All others are relegated to the class of *false croup*. Nysten, in his Dictionary, under the head "*laryngisme*", cites Marshall Hall as his authority for describing it as an example of reflex or diastaltic nervous action, and terms it "*laryngisme striduleux*". Under the head of "*faux croup*", he gives as synonyms, pseudo-croup, "*croup spasmodique*", *laryngismus stridulus*.

At all events, and this is the main purport of my communication, it is, in my opinion, highly desirable, for the sake of the public, as well as for the profession, that the term "*false croup*" should be applied and restricted to the spasmodic disease which is commonly called "*crowing inspiration*", or simply "*croup*". Sir Thomas Watson, with his usual felicitous use of the English language calls this "*bastard croup*", or "*spurious croup*". I would willingly adopt the latter term and speak of "*spurious croup*"; but for the public I think "*false croup*" is even better, for I suppose we cannot discard the word "*croup*". Whichever term be used, we thereby clearly separate from all other forms of laryngeal affection one, whatever may be its pathology, which is not inflammatory, is not attended by any form of inflammatory exudation, is not contagious, and, for the most part, is a far less serious malady, and which moreover, and this is of the highest practical im-

portance, demands a very different mode of treatment. The distinction is certainly not understood by the public, and, I fear, is too often not made by the medical attendant. For one not unfrequently finds that leeches, blisters, and antiphlogistic remedies of all kinds have been employed, in cases where a warm fomentation and a purge followed by some antispasmodic and mild sedative were all that the case required.

In conclusion, and in reference to the controversy now maintained as to the identity or diversity of diphtheria and the old English inflammatory disease, croup, I will venture to express my conviction that they are distinct diseases. So far as I know, I was one of the first to call attention to the outburst of diphtheria in this country, which took place about the year 1850, in which year I read before the Medical Society of London a paper (*Medical Times*, vol. i, new series, 1850) expressing my views as to the distinction between the disease described by Bretonneau and that with which English practitioners were familiar, as acute inflammatory croup. Though much more familiar now with diphtheria than I then was, I have seen no reason materially to alter the views expressed in that paper. Previously to that date the disease with which I, and I believe most other practitioners, were most familiar, was an acute inflammatory disease, beginning in the air-passages and amenable to strictly antiphlogistic treatment, and which Dr. Semple would call "laryngitis stridulosa". This designation is not, however, I think, a happy or desirable one, partly for reasons that may be gathered from what I have cited from French authors. The classification that I would suggest would be 1, false or spurious, or bastard croup; 2, acute inflammatory croup; 3, diphtheritic croup, or diphtheritic laryngitis. I do not touch the question whether the croup of Home and the cynanche trachealis of Cullen, etc., are or are not the same disease as that which is now called diphtheria. The absence of all reference to paralytic symptoms in the older writers is, however, remarkable.

A CASE OF CEREBRO-SPINAL PARESIS.

ACCOMPANIED BY INTENSE NEURALGIA AND CEREBRO-SPINAL IRRITATION.

By J. LOCKHART CLARKE, M.D., F.R.S.,

Physician to the Hospital for Diseases of the Nervous System.

A LADY, aged 56, in delicate health, and always subject to debility, with occasional pain in the back, had felt, about a month before I saw her, unusually weak and languid for a few days, and then experienced a severe pain along the spine, accompanied by a sensation as if the spine were stiff, or "as if it were drawn back by a tight cord". She also felt as if her neck were drawn back, but it was not so in reality. The pain along the spine extended to the back of the head, to the shoulders and scapular region, and was accompanied by a sensation of "pins and needles" in the hands and fingers. She complained also of shooting pains all over her head, but particularly on the right side; and, on the same side, she had the most intense pain over the brow, in the temple, and below the eye, along the orbital ridge of the malar bone, extending thence to the inner angle of the eye and side of the nose, and causing frequent fits of sneezing. There was some swelling of the brow and face. The pain in the brow extended upwards to the forehead and vertex of the same side. It was so severe, that she felt "as if it would drive her mad". These symptoms were accompanied by chills, flushes, and perspirations; but there was no continuous pyrexia. The pulse was small and rather quick. Her intellectual faculties became much impaired; she had confusion of mind, loss of memory, and felt so nervous and timid, that she was afraid to move about. In the course of a few days, she became very weak, and took to her bed. There was considerable tenderness on pressure at the back of the neck, and at several points along the cervical and dorsal regions of the spinal column. She was ordered citrate of iron and quinine, iodide of potassium, and Dover's powder at night, with counterirritation along the spine. Great improvement followed in a few days, and, at the end of twelve days, all the neuralgic pains had gone, but some tenderness remained along particular parts of the spine. When the neuralgic pains had subsided, she complained of great soreness of almost all parts of her body. The soreness was first felt on each side of her face, on opening and shutting her mouth, and the masseter muscle was tender to the touch. The soreness then extended down to the sides of the neck from behind the ears; then over the shoulders and back of the arms as far as the elbows; next down the back of the thighs and legs, but not in the feet. Her body and face became much emaciated, and the masseter muscles were evidently wasted. By continuing the use of the citrate of iron and quinine, with small doses of tincture of nux vomica, she was quite herself again at the end of a month.

This is an exceedingly interesting and instructive case. I have called it cerebro-spinal paresis, because the cerebral and spinal functions were much depressed. The correctness of the diagnosis was proved by the successful treatment.

ON A NEW AND EFFECTUAL METHOD OF ADMINISTERING CHLORAL AND BROMIDE OF POTASSIUM IN DISEASES OF WOMEN.

By G. DE GORREQUER GRIFFITH, L.R.C.P. Lond.,
Senior Physician to the Hospital for Women and Children, Pinelock.

MRS. M., aged 26, gave birth at her full time to a healthy male child, on Sunday, July 19th, 1874, being attended for me by Mr. Smith. The labour—primipara—was natural, and was completed within thirteen hours; but towards the close of it, the soft parts offered great resistance, which, however, was overcome by patient waiting, and without any manual interference, or any rupture of the perinæum. Everything went on well till the night of Saturday, July 25th, when it was necessary to draw off the urine, as none had been passed for twelve hours. In four hours, she was again seen; she had become restless, complained of not being able to sleep, and had a pulse fast and quick, but full and strong; she was feverish, and I therefore prescribed for her a diaphoretic aperient, which acted effectually. As she had not slept much the previous night, and was still restless, I gave her a sedative of opium and chloral, and had the vagina well washed out by means of warm water with Higginson's syringe.

On Monday, July 27th, acute puerperal mania declared itself unmistakably. She refused all kinds of food, as well as her medicine; would not allow the urine to be drawn off, nor the syringe to be used, and became very violent. Under these circumstances, I had to put her under chloroform, in order to do for her all that was necessary, and to procure her some sleep.

Tuesday, July 28th. She was put under chloroform three different times, and had done for her as on the previous day. I gave her subcutaneous injection of morphia, using one-third of a grain only. The chloroform acted quickly, very little being sufficient to anaesthetise her; it did not occasion sickness, nor any other bad symptom; but it did not assuage the delirium, which returned with the reaccession of consciousness. In the evening, while she was under the influence of the chloroform, I gave her a subcutaneous injection of morphia (one grain), which had the effect of prolonging the soporific influence of the former drug, and of producing great contraction of the pupil. The discharge from the uterus and vagina being somewhat offensive, the syringe was used every four hours, Cond's red fluid being added to the warm water. The child was removed the very first day the maniacal symptoms declared themselves, and the breast-pump was used to get rid of the milk.

Wednesday, July 29th. Chloroform was given at 9 A.M.; the patient was fed by the bowel; the urine was drawn off: a vaginal injection of warm water and Cond's fluid was given. At 1 P.M., chloroform was again given, in the same dose as in the morning, one grain of morphia being now injected subcutaneously. At 4 P.M., Dr. Cumberbatch and I met in consultation, and agreed to continue the administration of nutriment by the bowel; adding, however, to the egg and milk, half a wine-glass of pale brandy; and, as the morphia injections had not relieved the delirium, and had begun to aid in drying the tongue and mouth, and to induce other morphia symptoms, we decided to use an injection into the rectum of bromide of potassium one drachm, chloral half a drachm, mixed with the egg, milk, and brandy; and to repeat the drugs, if necessary, every four hours. Accordingly, at 5 P.M., I put her again under chloroform, and injected into the bowel the nutriment, having the medicines previously mixed. She slept for about six hours. At half past 11 P.M., as she was awake, restless, and violent, we gave her chloroform, and the enema, as at 5 P.M. She slept nearly the whole night soundly, awaking at intervals, but only for a short time, when she still raved, muttering incoherently, and then again falling asleep. On July 30th, chloroform was administered, and the nutrient enemata; but, as she was drowsy and quiet, the bromide and chloral were laid aside all this day. On the 31st, in the afternoon, the bromide and chloral were again given her in one of the nutrient enemata, which she had regularly every four or five hours.

Saturday, August 1st. She being quiet, having lapsed into a state of imbecility, and taking some nourishment by the mouth, as well as allowing the egg, milk, and brandy to be given her by the rectum, the chloral and bromide were discontinued; and I am happy to learn that, in the asylum, whither she was moved, she is convalescing.

The difficulties in this case can hardly be estimated, unless they had been witnessed, so strong was the patient and so violent; and it would have been impossible to feed her, or, indeed, do anything for her, without great violence, had chloroform not been administered. As, however, the effects of this speedily passed off, little ulterior good might have been wrought, but for the chloral and bromide, the sedative and good effects of which were quickly manifest each time they were used, acting apparently more rapidly than when taken into the stomach; nor was there any diarrhoea, or other irritant effect produced on the bowel.

In very many cases, this mode of giving chloral is, I consider, the best; since it does not nauseate, nor does it sicken, nor give that unpleasant taste in the mouth which remains long with some patients, nor does it occasion the burning in the mouth, throat, and stomach, of which many patients complain, a sensation which may be prevented in the rectum by beating up the drug with a raw egg, or even two raw eggs, a little warm milk being added to further the solution. One great advantage is that the gastric nerves are not affected, as they are when the medicine is taken by the mouth; in which latter case they seem completely deadened, or, as it were, narcotised, a result that tends to impair the appetite.

Since my experience in this case, I have used the chloral in half-drachm doses, with a lady suffering the agonies of gall-stones, and in whom the stomach was so constantly irritable that no medicine could be retained; chloroform inhalation to narcotism, morphia by subcutaneous injection, and every conceivable remedy, had been tried to allay pain, and procure rest and sleep, but had all failed. In ten to fifteen minutes after the rectal injection of chloral, pain was assuaged, and in half an hour sleep was procured. I have in this manner also used it when menstrual pain and sickness could perhaps have been relieved in no other way; also in cases of uterine and ovarian irritation, where pain, such as we have in those affections, varied from the mildest to the severest states. In irritable rectum, also, I have found it most efficacious, and have just commenced to use it as a vaginal suppository. In uterine, ovarian, and rectal cases, it is an especially valuable agent, inasmuch as it is brought into immediate contact with the affected nerves, and acts upon them directly, deadening any hyperæsthetic conditions, and relieving pain.

I have recently (end of April) seen the patient who was the sufferer from puerperal mania, and find her perfectly well in body, mind, and intellect, quick and vivacious, with no trace of imbecility remaining. The patient suffering from gall-stones, who had been for so long a time a sufferer without any relief, till the chloral was administered by the rectum, has remained quite well.

(*Brit Med. Journal*)

CLINICAL MEMORANDA.

CROUP AND DIPHTHERIA.

THERE appear to be two questions under discussion relative to croup. The first has reference to the meaning of the term, and the second to the nature of membranous croup. I take it that the former is to be settled by usage. I find that most medical men whom I meet in consultation apply the term croup to any acute affection where the symptoms denote a partial closure of the glottis. They cannot often know the exact nature of the malady, whether it be due to simple inflammation, or whether a membrane be present. This is a matter for after-diagnosis. They are, therefore, content to call the case one of croup, which is as good an expression as most other terms in medicine. The second question as to the nature of membranous croup is a very important one, both pathologically and clinically, since the answer either affirms or denies the existence of such a pathological condition as a membranous inflammation of the aerial mucous membrane. I speak of the mucous membrane as a whole, for I suppose no one would say that different causes were in operation according as larynx, trachea, or bronchi were affected, seeing that we may find the whole of the air-passages, from glottis downwards, covered by membrane. It is well known that nearly every pathologist in Europe has spoken of two forms of inflammation of the mucous membrane of the air-passages, the catarrhal or corpuscular, and the membranous or croupous, and clinical observers have acquiesced in this division. It is now maintained, and notably by two good authorities in London, that there is no such thing as an idiopathic membranous inflammation, but that, when found, it is due to a cause external or specific. A prevalent opinion is, that such membranous inflammation may arise under various influences; but the modern assertion is, that it is never idiopathic but always diphtheritic. As the question is not an anatomical one, but has to do with causes, it can only be settled by clinical observation.

SAMUEL WILKS, M.D., Physician to Guy's Hospital.

CROUP AND DIPHTHERIA.

IN the report of the observations I made at the Clinical Society (BRITISH MEDICAL JOURNAL, May 1st), on the subject of the identity of croup and diphtheria, I am made to say that I have "recently been converted to the view that croup and diphtheria are identical". I should like to say that this does not quite express my position; the observations I made were to the effect that, although I had long believed in the distinctness of the two diseases, this opinion of mine had recently been "rudely shaken"; and I instanced a case I had lately had under my care which would, probably, have been registered as croup if a *post mortem* examination had not shown it to be diphtheria. But, whilst I am entirely convinced that many cases of diphtheria have been registered as croup, I am far from believing that sufficient evidence has been produced to settle the question in favour of their identity, and I am altogether opposed to the tone of dogmatic finality which has been assumed by some on the identity side, as it is essentially hostile to that liberal and patient spirit of inquiry, which, in medical as in all scientific investigations, can alone lead to real advancement in knowledge. It has also occurred to me in connection with this discussion, that I have found a far larger experience and familiarity with cases of so-called croup, and with epidemics of diphtheria, amongst medical men in large general practice, especially in the provinces, than amongst the physicians of general hospitals in London. So far as I have been able to observe, cases of croup and diphtheria are comparatively rare in the general wards of London hospitals. As these cases are exceedingly acute and often rapidly fatal, I am inclined to believe that by far the greater number of them fall exclusively under the observation of our brethren in large general practice, and it is to them, therefore, that we should look for evidence which may decide this dispute.

I. BURNEY YEO, M.B., Assistant-Physician to King's College Hospital.

CROUP AND DIPHTHERIA.

IN the note on croup and diphtheria inserted in page 507 of the JOURNAL for April 17th, I need not say that I professed to give only a brief summation of my own experience in these diseases. I admit, with Sir John Cornack, that the nomenclature is unfortunate and open to misconception, and cordially concur with him in the views held by the French and other authorities, which he has so lucidly detailed. I believe that diphtheria and croup are as distinct as typhoid fever and pneumonia; that the former is a fever of low type, with or without, but generally with, evident local manifestations; the latter a local inflammation giving rise to general febrile disturbance, and both running a rapid course; and that the recognition of these distinctions is very important in prophylaxis and treatment. In answer to Dr. Semple's courteous notice, I can only say that, confining both diseases to children under the term of puberty, the characters of the membranes observed by me have been such as I described. That of simple membranous croup was firm, tough, light kid-coloured, its inner surface glistening, its texture elastic, when ejected during life or removed after death retaining its tubular form, and when cut transversely the edge clear and clean; that of diphtheria generally ash grey or dull white (*subalbicans*), like rice-paper that had been macerated, or, as Dr. Starr described it in 1749, "like an oversoaked membrane, which, being oversoaked, had become rotten"; when removed from the body collapsive, so that the tubular form was lost, and when cut transversely the edge soft and flabby. I may add, that many years elapsed after my acquaintance with membranous croup before I saw a case of diphtheria, and when I did, I had not the slightest difficulty in recognising the latter, and the marked difference of its exudation from that of the former. Perhaps Sir John Cornack may recall during his early professional life in Edinburgh, if he were attached to a dispensary especially, many cases of membranous croup with its characteristic membrane, for it was about that time and in the class of patients who frequented dispensaries that I chiefly met with it.

WM. CUMMING, M.D., Edinburgh.

OBSTETRIC MEMORANDA.

PUERPERAL INFECTION.

IN reply to the fourth question in Mr. Spencer Wells's address on puerperal fever, How can its spread be most certainly prevented or checked? and, in response to your call for any useful hint on this now prominent subject, I have pleasure in giving the plan which the late Dr. Dawson, Lecturer on Midwifery at Newcastle-on-Tyne, found

effectual in preventing a run of puerperal fever cases in his practice, and which has proved entirely satisfactory in my own. In 1863, I called on Dr. Dawson to see a case of puerperal peritonitis. My wife was at the time "daily expecting", and I naturally felt peculiarly anxious. On my way home, I told him my position and feelings, and put the question to him, What must I do to prevent more cases from occurring? Dr. Dawson at once asked, if I could use either hand in delivering? Yes. Then, said he, touch this poor woman with one hand only, and reserve the other for future cases; and, lest you should inadvertently neglect the precaution, you might put the mistrusted hand in a sling when called to a case. I warmly thanked the doctor, felt my weight of anxiety removed, nor have I ever had more than isolated cases of puerperal fever since. Before parting, I told Dr. Dawson that I had more than once observed my revered teacher, the late Dr. Patterson of Glasgow, with one arm in a sling, he must have adopted the same method. Undoubtedly, was the reply. Dr. Dawson's mode of preventing the spread of "childbed fever" would also be efficacious in cases of syphilitic infection. Had it been more in vogue, we might never have had to lament that distressing trial of Simpson and Wife v. Davey. That "puerperal fever" is infectious is quite granted in this district, for I have heard it styled "nail fever". Besides baths, disinfectants, change of clothes, and other preventative means, I would recommend the obstetrician, when first a suspicious case occurs in his practice, to discontinue the use of gloves, to walk in the sunshine, and if he have the opportunity, to do a little flower-gardening.

JOHN CARRICK MURRAY, M.D., Newcastle-on-Tyne.

REPORTS

OF

MEDICAL AND SURGICAL PRACTICE IN THE HOSPITALS OF GREAT BRITAIN.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL.

A CASE OF CÆSAREAN SECTION.

(Under the care of Dr. GRIGG.)

CASES of Cæsaean section are rare, and the modern improvements by which delivery is facilitated without recourse to this last resort of the accoucheur have rendered the instances which call for the operation so few, that its performance is always an occasion of painful interest. In the following case no other proceeding was open. Although in some respects the case was favourable, and although the operation was performed with skill, the mother died. The child, however, still survives; and there is, we believe, a good prospect that its life may be preserved.

Jane B., aged 38, married, was admitted on April 26th. She had been under the observation of Dr. Sloman of Farnham, by whom she was sent into the hospital. She stated that she was a native of London, being born near Holborn; that she had been delicate from birth, always subject to chronic bronchial catarrh and gastric disturbance. During the last five years, she had lived in the country, during which time her health had much improved. She had intercourse on July 29th last, quickened a fortnight before Christmas, and married shortly after Christmas. She believed that she became pregnant in July. Gestation was normal, with the exception of slight increase of gastric disturbance, coupled with much sleeplessness. Her parents were healthy; two brothers and one sister were living, healthy and well formed. She was the last but three of eleven children; those younger than herself died at early ages. None of the family were deformed.

When admitted, she presented a worn attenuated appearance; her height was forty-two inches and a-half; her head was large; the lower third of the spine was sharply curved forwards; the mammae were large; the chest was of fair size, but deformed; the spine was, as it were, driven in. Her arms were small; her hands large; her thighs straight; the legs were much curved anteriorly, being bent like the letter S. External measurement of the pelvis by callipers gave eight inches from one anterior superior spinous process of the ilium to the other, and from the sacrum to the pubes four inches and a half. A vaginal examination showed the conjugate diameter to be one inch and five-eighths. The pelvis was oblique, the left side being less developed than the right, with the right wing of the ilium much bent in. The depth of the pelvis was slight, but the cavity was roomy. The axis of the inlet was nearly at

right angles with the perpendicular line of the patient's body. The breech was found by external palpation to be presenting. She was examined by Drs. Brodie, Hope, and Greenhalgh. On account of the peculiar direction of the axis of the inlet, it was thought impossible to attempt craniotomy with any chance of success; Cæsarean section was, therefore, decided upon.

The operation was to have been performed on April 30th; but, labour having set in prematurely on the morning of the 29th, at eleven o'clock, the operation had to be hastened, and was performed at 5.50 P.M. on the latter day. The membranes ruptured at one o'clock. At 5 P.M., the os was two-thirds dilated; the breech could be felt high up; the pains were strong and frequent. There were no signs of the breech entering the brim. Pulse 130. Temperature normal. The vagina was cool and moist. The patient was placed under methylene by Dr. Gordon; and, in the presence of Sir William Fergusson, Mr. Spencer Wells, Drs. Brodie and Waters, and Professors Simpson of Edinburgh, Helmholtz of Stockholm, Netzel of Christiania, and Stoltz of Nancy, Dr. Grigg made an incision beginning at two inches and a half above the umbilicus, and extending to within one inch and a half of the pubes. The various structures were carefully divided. On opening the peritoneal sac, about a pint of serous fluid escaped. The bladder reached to within an inch and a half of the umbilicus; and some care was required to avoid cutting it. The uterus was opened by an incision commencing about the middle of the body of the organ, and extending in a direct line downwards to within two inches of the external os. The fetus, whose back was foremost, was rapidly and easily extracted, as was also the placenta removed, which was seated at the fundus and posteriorly, with only slight hæmorrhage; the uterus contracting firmly. The bleeding was not much throughout. In dividing the cervix, a large vessel was cut through, which bled for the moment freely. A continuous silken suture was placed in the uterine wound, the end being passed down through the vagina; it was not tied at either end. This was a plan recommended by Mr. Spencer Wells, and the suture was placed in by himself. The abdominal walls were brought together by interrupted silken sutures. The patient rallied, and did very well up to 2 P.M. on the following day, when she suddenly became hot and then cold; was delirious at 4.30; and died collapsed at 8.50 the same evening. She, however, kept nothing upon her stomach from the time of the operation. The child, a boy weighing over six pounds, is living.

At the *post mortem* examination, the measurements of the pelvis were verified, and were found to correspond exactly with those made out during life. The upper third of the abdominal wound had healed; the uterine wound was patulous, and the thread suture had worked out of the upper half. There were very slight signs of peritonitis in the immediate neighbourhood of the wound. The cavity of the uterus and the uterine wound were bathed with some turbid fluid which escaped externally on dividing the abdominal sutures. The abdominal wound measured four inches, and the uterus the same. The apex of the incision was three inches from the apex of the fundus, and one inch and three-fourths from the external os.

NEWCASTLE-ON-TYNE INFIRMARY.

REPORT OF A CASE OF LYMPHÆMIA.

By G. H. PHILLIPSON, M.A., M.D. Cantab., F.R.C.P. Lond., Physician to the Infirmary, Lecturer on Medicine in the University of Durham College of Medicine.*

RALPH M., aged 40, a tobacco-pipe maker, resident in Gateshead, was entered as an out-patient at the Newcastle-upon-Tyne Infirmary, under my care, on July 9th, 1874. He stated that he had been in weak health for five years; that he had been aware of a swelling in his abdomen for two years; that, for the past six months, his breathing had been hurried; and that he had been rapidly losing strength, having suffered from epistaxis, sickness, and diarrhoea; and that for six weeks the right side of the neck had been swollen. He also complained of fleeting abdominal pains. Upon interrogation, he admitted to having had syphilis fifteen years ago, and to having led a very dissolute life. Upon examination, the abdomen was enlarged, visibly so on the left side. Upon palpation, the left hypochondrium was found to be occupied by a hard tumour, which was dull upon percussion. The dullness extended nearly to the middle line in front, and from the sixth interspace to two inches below the umbilicus. The anterior border was sharp and hard, and was distinctly notched. The tumour felt near the surface, but was unable to be moved; yet the hand could be passed behind it. Its position remained unchanged in forced inspiration and expiration. The blood was examined microscopically, and it was found that there was a

* Read before the Northumberland and Durham Medical Society.

considerable diminution of the red globules and an increase of the white.

The tumour was regarded as an enlarged spleen; the diagnosis being based upon its position, its nearness to the surface, its sharp and notched anterior border, and the ease with which the hand could be passed behind it. It was surmised that the organ was bound to the abdominal wall, which would explain its immobility.

He was advised to enter the institution, but declined. He was ordered to take iodide of potassium internally, and to rub the compound iodine ointment over the enlargement of the neck and the swelling in the abdomen. On August 2nd, he was made an in-patient. He was greatly emaciated, and very anæmic; the lips and conjunctiva were almost white, while there was a peculiar fawn or orange tint about the eyelids. The pulse was 106, and the temperature 100.4 deg. Fahr. The face and head were considerably swollen from œdema. The right leg was œdematous. The lymphatic glands on both sides of the neck, and in both axillæ and both inguinal regions, were enlarged and hard. Upon examination of the abdomen, it was found that the tumour extended fully three inches to the right of the umbilicus; upwards, as high as the sixth interspace, and downwards, within two inches of Poupart's ligament. There was distinct fluctuation in the abdomen. No *bruit* was heard upon auscultation over the tumour. The heart's impulse was visible about half an inch within the left nipple and in the nipple-line. The heart-sounds were feeble, but without murmur. Upon examination with the ophthalmoscope, it was noted that the optic discs were normal, but that the fundi were extremely pale. The urine was of specific gravity 1028, and contained albumen, but no blood-corpuscles, pus-cells, or casts of the uriniferous tubules. He was ordered a generous diet, wine, and the tincture of the perchloride of iron.

September 2nd. From time to time, he suffered from diarrhœa, which was restrained with the chalk mixture and catechu, and the compound powder of ipecacuanha. He gradually became weaker, and died on September 20th.

NECROPSY, forty-five hours after death.—The peritoneum contained a small amount of clear yellow serosity. The spleen was adherent to the abdominal wall, the left lobe of the liver, and fundus of the stomach, by old and firm adhesions. The surface of the organ was slightly uneven, and indented by the ribs. It measured 12 inches in length, 9 inches in breadth, was 3 inches thick, and weighed 7½ pounds. Upon incision, it presented a mottled appearance, was reddish-brown in colour, very firm and tough, and was not impressed by the finger. Microscopical examination showed the normal elements, only they were more closely packed together. The increase appeared to be owing to proliferation of the cell-elements. The liver was not adherent to the abdominal wall; it was smooth on its surface, and, upon section, was of fair consistence, and a little pale in colour. The kidneys were enlarged; the right measured 5½ inches in length, and 3½ inches in breadth. The capsules were easily removed, the exposed surface being pale and smooth. On section, the cortical portion was increased, at places to half an inch in thickness. The suprarenal capsules were large; the right measured 2¼ inches in length, and 1½ inches in breadth. The mesenteric and lumbar glands were enlarged, the largest being fully half an inch in length. The pericardium and pleura contained clear yellow serosity. The heart was small and loosely contracted. The muscular tissue was pale and soft. The valves were normal. The coagula were greyish, and, when examined microscopically, were found to be composed entirely of colourless blood-cells. The lungs were emphysematous, especially at the anterior and lower borders. There was no tubercle. The bronchial glands were enlarged. The thyroid gland was not larger than usual. The glands in both axillæ, in both inguinal regions, and on both sides of the neck, were enlarged. The largest gland in the right inguinal region measured three inches in length. On section, the glands were pale, mottled, and were soft and watery-looking. The cortical substance was particularly swollen, in some to the thickness of one half or three-quarters of an inch. The microscope showed that the increase was entirely due to an excessive formation of cells, nuclei, and granules, similar to those of the normal glands.

REMARKS.—The interest of this case is the association of the enlargement of the spleen with the enlargement of the lymphatic glands, peripheral and central, and with the condition of the blood, designated leucocythæmia or leukaemia, in which the white corpuscles are in excess. The anatomical characters of the lymphatic system, however, being so markedly predominant, the case has been recounted under the title of lymphæmia, as a more appropriate term than leucocythæmia, the latter being regarded as expressive of the condition of the blood alone, and not necessarily associated with hypertrophy of the spleen or other blood-glands. The abdominal tumour, from its immobility, if the physical signs had not been carefully interpreted, might have been re-

garded as an enlarged left kidney, and not an enlarged spleen, the supposition of its fixation being clearly verified at the necropsy; the tenseness of the adhesions indicating old localised inflammation of the peritoneum in the neighbourhood of the spleen.
